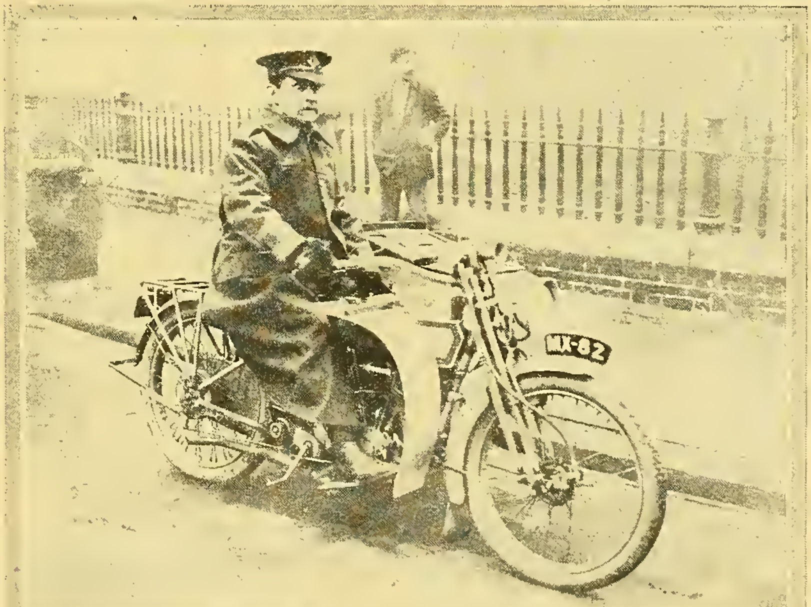
Service entertainments behind the lines, in hospitals, and on board ship are quite a feature of the social life of our soldiers and sailors. An excellent effort in this direction, in the opinion of a former member of our staff who has witnessed many such entertainments, was a revue staged a few days ago by what is considered to be the crack squadron of the R.N.A.S. The subject of the revue was the introduction of women into the Service, and both officers and men were in the caste. One hesitates to think of what Nelson would have said had he seen air mechanics dressed as girls and parodying well-known songs instead of changing sparking plugs and such-like duties that form part of the daily routine.

Women Motor Drivers Inspected by the Queen.

The Queen inspected a large number of women, representing the Women Motor Drivers' Section of the Women's Legion, on Saturday morning, in the gardens at Buckingham Palace. There were 160 dismounted women and sixty-five on vehicles, representing 2,000 women motor drivers belonging to the Legion in different parts of the country. Five specimen vehicles were drawn up in front of the garden entrance to the Palace—a staff car, a touring car, a motor cycle for a despatch rider, a box-body van, and an ambulance.

The Queen was particularly interested in the work of the women despatch riders and learned that they "carried on" during air raids.



A Harley-Davidson, fitted with aluminium leg shields, seen at the parade of the Middlesex Motor Volunteers, last Sunday.

10,000 MILES WITH A DYNAMO LIGHTING SET.

Experiences and Technical Tests of a Lucas Lighting Set.

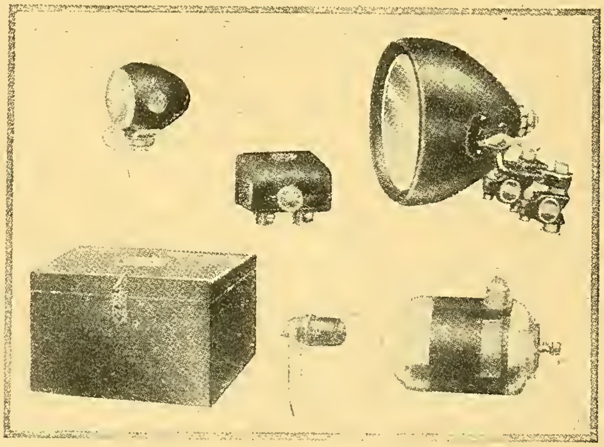
FROM time to time descriptions of electric lighting sets appear in the pages of *The Motor Cycle.* These articles generally deal with the early life of the lighting set and refer to its behaviour during that period, and it is not usual for the question of deterioration and wear to be discussed very fully. As this information is a matter of much importance to the majority of buyers, its omission is to be regretted.

During a period of thirty-four months the writer has had a Lucas dynamo lighting outfit in use on his motor cycle and sidecar, and he has made at intervals a careful examination of the condition of the various units.

The Drive.

In his experience only one feature has deserved criticism, and it concerns the drive from the engine shaft to the dynamo. The transmission is by means of a rather long chain, and due possibly to the lightness of the chain and to the high speed that it attains, the rollers have persisted in breaking. Each chain has had a life of about 2,000 miles only, which performance falls far below that of all the other parts of the lighting set and of the motor cycle itself. In comparison, the original driving chains of the latter are in use after 10,000 miles and they still show no need for replacement. In later models of the motor cycle concerned a Whittle belt drive has been adopted, and, judging from the results obtained on car installations, this type of drive should be expected to prove very satisfactory.

The dynamo has shown absolute reliability and appears now in perfect condition. No replacements have been necessary, and nothing has been touched except for an occasional oiling and a rare "look inside" to satisfy oneself that everything is in order.



The Lucas dynamo lighting set for a sidecar outfit.

The lamps, switchbox, and wiring have given unfailing service, and there has been no call to disconnect them.

The Battery.

Storage cells form the most vulnerable part of any electric lighting set, as they are so susceptible to misuse. This danger, however, is greatly minimised in a dynamo lighting system. After the outfit had been in service for some time the thought occurred to the writer that it would be instructive and interesting to record by means of capacity tests the wear and tear on the battery throughout its life. Accordingly tests are being made at intervals, which, indicating the condition of the cells, will show finally when replating becomes a necessity.

The capacity of a battery is usually expressed as the product of the current in ampères and the number of hours during which the battery will deliver this current on discharge before the e.m.f. falls to the average value of 1.8 volts per cell. In other words, it is the useful output of the battery, and it determines the period during which the cells will light the lamps before a recharge is necessary. This knowledge, for instance, would be of great value if the dynamo chanced to fail.

In the Lucas lighting set the current ordinarily supplied by the battery, when the machine is stationary and the dynamo at rest, is approximately 1.5 ampères—assuming the user has switched his head lamp over to its reduced lighting, as he should do, and the tests described were made with this discharge current.

It may be well to point out here that the smaller the discharge current the better output performance will a battery show; and in general it will be found that the ampère hour output marked on the label is only obtained when discharging at currents considerably below the stated maximum current.

Testing Methods.

The procedure of the tests consisted in first fully charging the battery at its stated charging current of 2.5 ampères until the cells were "gassing" freely. This was continued until the voltage per cell reached the value of roughly 2.2 volts, when the charge was taken to be complete. In discharging the battery an adjustable resistance and an ammeter in series with it were connected across the battery terminals. The circuit was closed, and by means of the resistance the

0,000 Miles with a Dynamo Lighting Set.—

current was adjusted to and maintained at 1.5 ampères hroughout the discharge.

Initially and at intervals of one hour until the completion of the discharge the voltages across the battery terminals, and also across the individual cells, were measured. From these values curves of discharge were plotted.

The Tests.

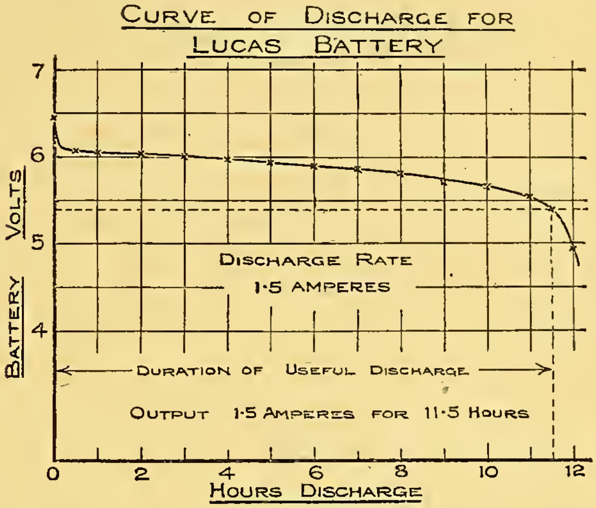
The first test was carried out in August, 1915, the second in October, 1916, and the third in November, 1917, and the values obtained in each case have been identical—a result which is most gratifying. One discharge curve therefore illustrates graphically the results of all the tests. This curve, which is shown, is of the characteristic form. Initially the voltage of the battery is 6.4. Then for a short period a rapid fall of voltage occurs, followed by a slow gradual decrease until nearing the end of the useful discharge, when the rate of fall becomes more and more rapid. A voltage of 5.4, or an average of 1.8 volts per cell, was reached in each test after discharging for 11½ hours, which gave for the battery a capacity of 17¼ ampère hours.

In discussing the results of tests of this character it is well to consider the conditions under which the apparatus has been used, in order to value its performance more truly. The mileage run, although not high on account of the many restrictions, constitutes a respectable total, and it may be taken to give a sufficiently representative test on any lighting system. Faults and weaknesses in design, materials, and workmanship may reasonably be expected to reveal themselves over this distance.

There is little doubt that the present excellent results are due in a large measure to the provision of a dynamo in the system. As a consequence, the battery is always in a more or less charged state, and it does not often reach that condition in which "sulphating" with its cumulative deleterious effects becomes appreciable.

Further, the rates of charge and discharge are never permitted to exceed values at which the plates would tend to buckle and disintegrate. These latter effects are a frequent source of poor performance in batteries fitted to self-starting sets on cars where discharges at a very heavy rate often occur.

Another factor, which perhaps has contributed to the excellent results obtained, is the periodical charging and discharging that the writer has carried out. A moderate amount of regular work is essential to keep a battery in its best condition, and it has been the practice during periods when the lamps are rarely used, as, say, in summer, to disconnect the battery at intervals and subject it once or twice to a charge and discharge at a low rate, half an ampère being the rate adopted.



The dynamo lighting system for motor cycles undoubtedly has come to stay, and, when well designed and constructed, it gives service in lighting, convenience and life second to no other system. A.K.

Wintry conditions at New Zealand headquarters. The motor cyclists have to "carry on" in spite of inclement weather. (*Official.*)

HOW TO JOIN THE R.A.F.

Provisional Regulations governing Temporary Commissions as Flying Officers.

THE following details will be of interest to the younger section of readers whose ambition it is to enter the Air Force. Many of our readers have shown the liveliest interest in all that pertains to the Air Force, and further information likely to interest them will be published as soon as it is available.

The earliest age at which a candidate can be admitted to an Officers' Cadet Wing is 17½ years, but applications can be received and decided upon earlier.

Candidates over thirty years of age are not eligible.

Applications should be made in letter form, stating full particulars regarding the applicant, and should be addressed to the Director of Air Organisation, Room 29, Air Board Office, London, W.C.2.

After March 31st applications should be addressed to the O.C. Reception Depot, Royal Air Force, London, Birmingham, Bristol, Cardiff, Glasgow, Leeds, Liverpool, Newcastle, or Nottingham, according to the district in which the candidate is registered.

Service candidates must in all cases apply through their Commanding Officer (on Army Form M.T. 393a, if soldiers).

Admission is by selection, subsequent to an interview with an officer detailed for the duty, and after passing the prescribed medical examination.

Candidates are required to be of pure British nationality, the sons of natural-born British subjects on both sides. No variation from this rule is admitted.

Civilian candidates are required to attest before entry into the Officers' Cadet Wing. Full instructions are issued to each selected candidate.

The pay of a cadet is 1s. 6d. per diem, uniform, messing, and quarters found.

The course at the Cadet Wing lasts for about two months. This course is devoted to instruction in military duties and drill, and ends with an examination in these subjects.

Cadets next proceed to a School of Aeronautics for a six weeks' course of instruction in technicalities, such as engines, appliances, the construction of aeroplanes, and theory of flight; and thence to a School of Armament for a four weeks' course of gunnery instruction. At this stage in their training cadets may volunteer for the particular type of aircraft (aeroplanes, seaplanes, airships, etc.) for which they desire to be trained.

Cadets who successfully pass through the above schools will be appointed Flight Cadets or Sergeants with pay at the rate of 7s. 6d. per diem (plus 4s. per diem flying pay) and 3s. 6d. per diem (plus 1s. per diem flying pay) respectively.

Thence they advance to Training Squadrons, where they learn elementary flying on service machines under service conditions, proceeding to air tactics, bombing photography, and artillery observation.

On graduating from the Training Squadrons, Flight Cadets are gazetted 2nd-Lieutenants, and Sergeants are promoted Technical Sergeants, with pay at the rate of 10s. per diem (plus half flying pay, 4s. per diem) and 6s. per diem (plus half flying pay) respectively.

On graduating, 2nd-Lieutenants and Technical Sergeants obtain full flying pay (8s. per diem), and are entitled to wear pilot's wings.

Whether a cadet is eventually selected as an officer appointed as a non-commissioned officer or finally rejected depends upon his progress and recommendations while serving as a cadet. Cadets may have to pass a further medical examination before they begin to fly.

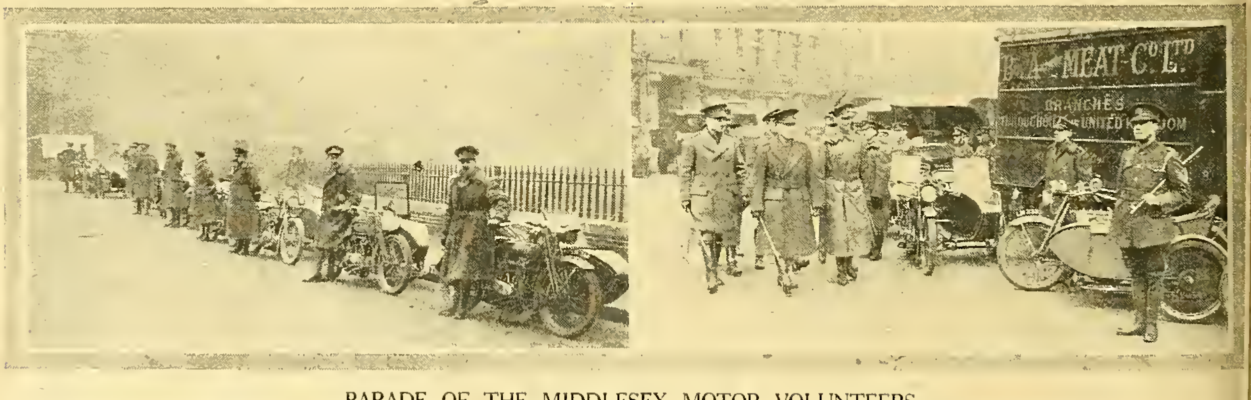
AN ATTRACTIVE POST-WAR MODEL.

A MODEL for after the war which has not been very much touched upon is a really T.T. two-stroke lightweight, having 26in. wheels, semi-T.T. bars of attractive design, and a light two-speed gear box. Most of the post-war two-stroke designs I have so far seen all tend in the direction of being heavier than their predecessors. Their designers are apparently out to produce a reasonably light and perfectly comfortable touring mount in preference to the mere runabout heretofore, but is no one going to cater for the speed merchant who wants something really light and cheap?

Some time ago I possessed a machine of the type I have in mind, and can honestly say that I obtained more genuine sport from it than any other machine I have owned. All superfluous weight was stripped even the rather heavy gear box eventually, as the second speed was seldom required, and at last the machine was so light that a temporary stoppage added to the sport of things.

One cannot help but think that a really fast lightweight, having aluminium parts as far as possible and designed throughout for speed, would meet a read market after the war.

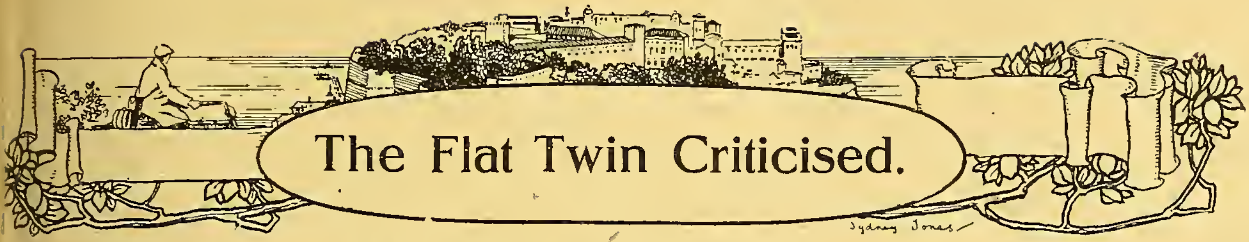
CHINOOK.



PARADE OF THE MIDDLESEX MOTOR VOLUNTEERS.

(Left) The parade of the motor cycle attachment of the 13th Company of the County of Middlesex Motor Volunteers.

(Right) Inspection by Lieut.-Col. Walter Gibbons, officer commanding the group. The parade, which took place on Sunday last at West Smithfield, near St. Bartholomew's Hospital, included commercial lorries and private cars as well as motor cycles.



The Flat Twin Criticised.

Advocating the Vertical Twin as the Best Type of Engine.

NOW that the flat twin is about to sweep the motor cycle arena of all competitors, I feel bound to express my views that this type of engine merits early grave, unhonoured and unsung. Do not ugh. I am justified by the well-known precedent of e *Skibbereen Eagle*, which, some time ago, had its e on the Czar of Russia. And think of the latter's te! It is well known by everybody, outside the otor trade, that all motor cycle manufacturers secretly eal their designs from the "Letters to the Editor" olumns, and so put the salary of a drawing office pert into their own pockets.

Therefore let me allay the anxiety of these poor men to what their post-war productions are to look like. therwise they are quite likely to fall into grievous ror, and go in bald-headedly for flat twins.

There are only three types of engine at present in ew worthy to survive on motor cycles. (1) The ngle. (2) The side-by-side twin, balanced as a single, it with even firing impulses. (3) The four-cylinder.

The Four-cylinder.

Looked on purely as an engine, the third is the st, but the manufacturers do not yet see its defects, they are not likely to supply it for some time. As on as the manufacturers realise that it is impossible supply a four-cylindered motor cycle with an ficient transmission, they will flood the market with and the public will at last get the shaft drive has been clamouring for for so long. "Just like a r." What a number of inefficiencies those words ld and make resplendent.

But as No. 1 is known to all, and No. 3 is still in e distant future, let us consider what advantages o. 2 has over the V and flat twin.

The Vertical Twin.

Over the V it scores in (1) bearing area, (2) accessi-lity, (3) torque, (4) intensity of magneto spark, (5) ction on carburetter, and (6) better cooling. It loses width of engine, and (theoretically) on balance.

Over the flat twin the side-by-side scores on (1) aring area, (2) accessibility, (3) ease of fitting into iangular frame, (4) overall length, (5) induction ping and carburetter position, and (6) better cooling. loses again on width of engine and (actually) on lance.

I contend that width of engine does not matter, as enables the final drive from countershaft to be on e same side of the machine as the primary drive, saving twisting strain on the gear box so usual in esent-day machines. Before leaving the width ques-on, let me state that the engine I contemplate is aluminium or copper *monobloc*, with steel liners, etachable head (no valve caps), exhaust valve over let in front of the cylinders, carburetter in bottom centre of block of cylinders, with induction pipe cast integral with cylinders. Such an engine, even in the 1,000 c.c. class, need not be too wide.

But the point I really wish to make clear to those manufacturers who hang trembling on my words is that torque is far more important than balance. And the parallel twin balanced as a single is superior in torque to any V and equal to any flat twin made.

On torque depends comfort of rider, and life of tyres and transmission. If anyone believes that balance plays a more important part in his comfort let him get the best balanced flat twin in the world and fix one cylinder (either by attention to plug or inlet valve) so that it only fires intermittently. He still has his perfect balance, but I defy him to believe that his machine is as comfortable to ride as a badly balanced single.

It is the even torque that really makes the difference. A parallel twin could easily be turned out just as comfortable to ride as a flat twin—at any rate, up to 50 m.p.h., which is far faster than the average tourist ever goes, in spite of what his speedometer may tell him.

I say that, with an outside flywheel, the ample width of big end bearing area, the genuine accessibility of the engine (especially if the crank case be split horizontally instead of vertically), the ease of housing in a strong frame, the simplicity of properly warming the carburetter and induction pipe, as well as the ease of cooling equally both cylinders, make the parallel twin with even torque well worth a place in the post-war policy of any manufacturer. And I prophesy that the scramble to make and discard flat twins will be very like the scramble to make and discard the worm drive, which took place in the car world a few years before the war.

A TILTER AT WINDMILLS.

THE DIRGE OF THE CARBURETTER.

You thought you were above decay
Upon your pedestal of clay.
The tricar vanished in its pride,
Accumulators came, and died:
You saw the trailer's final rout,
Hub gears came in—hub gears went out,
And belt drive tottered on its throne.
Of all the parts you stood alone.
Each year your pipes were cankered through
With juice of still more heavy brew.
With substitute we wreaked our wills.
Your float was caked with petrol pills.
You even swallowed paraffin,
But now at last your checks are in.
Begone! The weak must leave the race:
A *gas tap* comes to take your place.

E.P.B.

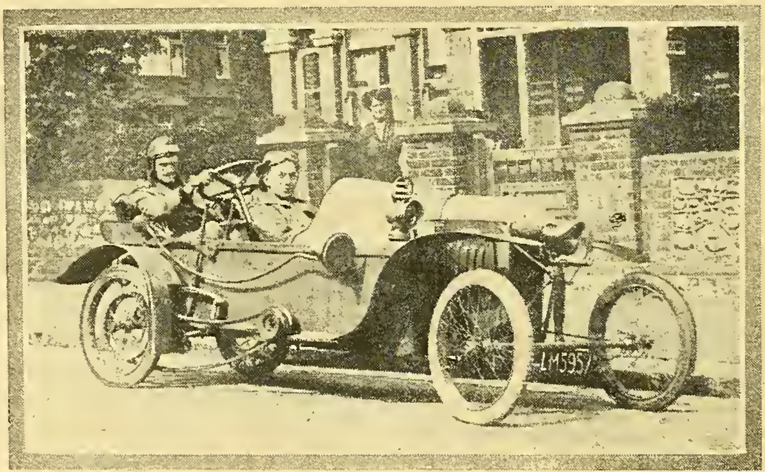
HOW ARE THE MIGHTY FALLEN.

A Motor Cyclist's Experiences with a Cycle Car, and some Comparisons.

THIS is the sad story of a fall from grace—of a time when I was lured from my loyalty to the single-track machine by the specious attractions of four wheels to sit over, and the right to say in an off-hand manner "my car."

This vehicle, which I drove without sustaining any permanent injury for five mad months, was called a "Sabella." There is no need for me to dilate upon her appearance, you may study it for yourself. She taught me a great deal about motors, and she provided more thrills than were ever undergone by Elaine, or Sexton Blake. I shudder now to think that this photograph was taken fifty long miles from home, and of what intervened before I got there.

In an ill-starred hour I sold my reliable but overgeared Rudge-Multi, and drove this horror—this mechanical impossibility—right across London on a Saturday morning. She started by a pull on a leather strap wound round a pulley, and jerked upwards. When the strap did not break, with resultant shocks to one's nervous system, occasionally she started. Her aged Bosch magneto was a prolific source of trouble. She had no clutch, and the drive was engaged by the tightening of sliding pulleys on the double belt drive. Occasionally a belt would fall off and trail, like the first serpent, in the dust. Pedestrians would wave frantically at you, and you would descend and put the thing back (not daring to stop the engine, which raced furiously the while, with a sound as of all Vulcan's smithy coming from the loose dogs). Clambering back hastily before her 8 h.p. Jap engine overheated, you let in the drive. The engine often chose to stop dead. After a lapse of time best indicated in the way favoured by Mr. H. G. Wells when denoting a crisis . . . . she would be got going again.



The cycle car on which the adventures occurred.

Speed—Useful and Otherwise.

Theoretically of infinitely variable speed, her normal was 30 m.p.h. This was occasionally awkward in traffic, as the engine had to be cut off at intervals. This sounded racy, but the dread of a total stoppage blighted any satisfaction to be got that way. Her steering was by steel stranded cable, which wound round numerous ingeniously placed bobbins, fraying through on an average once in six weeks or so. I can still recall the awed feeling that came over me when at the bottom of Westerham Hill, which I had descended in the manner of Boillot on the Grand Prix Peugeot, I found that of the three strands which com posed the cable, only one remained. And my sub sequent tame progress home.

Some Advantages.

Once she baulked half-way up Bury Hill, and w sojourned for a while in the chalk quarry there, smol ing our pipes until such time as her almost incar descent engine should cool down. Her one goo point was her freedom from vibration: the tande seating, with its attendant long wheelbase and ham mock seats, gave real comfort. But the passenger i front experienced sensations akin to those felt whe making a trial run on a torpedo boat destroyer, fo the madly pulsing engine was right under the incline footrests. When the tanks were not leaking through th terrific vibration of the badly mounte engine on its ove light wood fram the brakes require attention, or th wheels (equippe with ball bearing as tiny as those i the head of a pus bicycle) were out o track. She a t tyres. In greas weather her narro tread and habit o insouciantly waggin her tail kept yo heart in your mout If she ever had go over there is n much doubt th she would have rolled like a shot rabbit.

On occasion she would get a good mood, and tal the bit between her teeth. One morning very ear I came up from Worthing. Even the Findon tr was not working at that hour, and there was no nee for that restraint that she loathed so much. I s the throttle wide open and let her have it. I wou not tell you how long we took to get to Town, but is a memory to be cherished now that motoring h become a crime!

On Handcross one day returning from Brighton t vibration set up by her efforts on the hill fractured h petrol feed pipe hopelessly. She shed tears of t best Shell copiously (I never dared check her co sumption), and it was the dickens of a job to mend h Later on the way home she smashed a valve. T mushroom fled heavenwards through the front cylind I chartered a small boy collecting the wherewithal fertilise the garden on one of those ambulant Ta sugar boxes on pram wheels to help me to pu "Sabella" to a garage. He was manifestly u willing to abandon his cargo in favour of my cy car, but the offer of fourpence decided him.

I have never sat in a cycle car since, and never v again.

LETTERS to the EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

CARBURETTER ADJUSTMENT.

Sir,—The letter by H. A. Connell, *re* failure to obtain the full power from a Binks, causes me surprise. I have had a Binks fitted to a standard 1912 Triumph, and I am perfectly satisfied with the results—easy starting, flexibility, slow running, speed, acceleration, and plenty of power even with a main jet. The jets used were 0, 3, and 7.

Being so pleased with the Binks, I fitted one on a T.T. Singer, with the same results.

Is H. A. Connell sure it is the fault of the carburetter and not of the machine? I may also say that I have used even a 10 jet; in fact, jets as they are not intended to be used. If at all possible, I should very much like to have a try at H. A. Connell's Binks. PRIMUM MOBILE.

Widnes.

THE A.A. AND THE UNITED COUNCIL.

Sir,—I enclose herewith a copy of a letter that I have addressed to the Automobile Association and Motor Union in reply to the statement issued to the press under the signature of the Secretary of the A.A.

HORACE WYATT.

[COPY.]

THE UNITED COUNCIL OF MOTOR USERS, PRODUCERS, AND DISTRIBUTERS.

Secretary's Office, 39, St. James's Street, S.W.1,
March 14th, 1918.

Dear Sir,—My attention has been drawn to a statement appearing over your name and dealing with the views of the A.A. in respect of the United Council of Motor Users, Producers, and Distributers. I am particularly glad to note that the A.A. welcomes the co-operation of kindred bodies wherever and whenever the interests of the reasonable motorists are concerned, also that the committee of the A.A. are in entire sympathy with the suggestion of united action by all bodies concerned on matters pertaining to the production, distribution, and use of motor vehicles which may be affected by legislative or other proposals. Further, that the A.A. has at all times worked amicably with the motor producers and distributers.

Under these circumstances it appears that the objection of the A.A. to co-operate upon the suggested Council was based almost entirely, if not quite, upon a reading of one specific paragraph in the terms of reference of the Council as originally defined. This paragraph reads as follows:

"In respect of legislation, kindred matters and technical questions in relation thereto, to use its influence to discourage any organisation represented upon the Council from acting in a manner calculated to impede the policy or to injure the interests of any other organisation so represented, and to encourage united action and mutual support between all these organisations."

It is, of course, fully recognised by those who desire to collaborate that the Council is as yet in an embryonic form. May I suggest, therefore, that the A.A. could consider nominating any member or members of its committee to meet the Council as at present constituted, with a view to considering whether any apparently objectionable features in the terms of reference of the Council could not be eliminated by joint agreement, and the reason for the abstention of the A.A. thus removed?

I think your committee will agree, on further consideration, that the all-important matter of good roads referred to in your letter is of importance, not only to the motor user, but also to the producer and distributer, inasmuch as the markets of these latter are largely dependent upon the quality of the roads available for their vehicles; similarly it is in the interests of the producer and the distributer that motoring should not be discouraged by heavy taxation, and that ample supplies of cheap fuels should be made available. Thus there appear to be many subjects with regard to which discussion between motor users, producers, and distributers might reasonably be expected to lead to some unanimous decisions, which all could unite in putting into effect.

Admittedly there are points upon which the policies of the various sections mentioned must necessarily differ, but in many such instances private discussion may, I believe, serve to prevent unnecessarily antagonistic statements from being made in public. The paragraph quoted above, to which the A.A. takes exception, was really intended, as I understand it, to provide that public action of a hostile character should not take place until the matters in dispute had been privately discussed, and those who might be inclined to be unreasonable had thus been given an opportunity of reconsidering their attitude and taking a reasonable view. As a tentative suggestion that might form a basis of discussion, I do not think it unreasonable to suppose that those who have decided to support the Council would be prepared to modify the paragraph to read:

"To discourage any organisation represented upon the Council from acting in a manner calculated to injure the interests of any other organisation so represented until the views of both parties have been made a subject of discussion at a meeting of the Council; also to encourage united action and mutual support between all these organisations so far as may be found compatible with the effective freedom of action of each organisation in the interests of its membership."

I trust to hear from you that the A.A. will be prepared to discuss this or some other amendments, and should be pleased to convene a meeting of the Council for the purpose of such discussion upon a date convenient to the A.A.

HORACE WYATT, Hon. Sec. *(pro tem.)*

The Secretary, The Automobile Association and
Motor Union,
Fanum House, Whitcomb Street, W.C.

PETROL AND OIL ECONOMY.

Sir,—I begin to fear that his machine-gunning experiences are having an unhappy effect upon "Ixion." At least that is the only explanation I can think of for the curious statements he has been firing off recently. Only a few weeks ago he was talking about his "freak" gear of 4½—1. Now I can see nothing "whimsical or odd" (Webster) about such a gear, even if his machine does weigh over 300 lb., which I doubt; in fact, I doubt if any 3½ h.p. three-speed—and far less a four-speed—machine is supplied with a much lower top gear as standard for civilian use. Again, even if "heavy stress" is not laid on his figures in a recent issue *re* "per b.h.p. hour," they are extraordinary. He apparently refers to a machine in the 550 c.c. class to give 3 h.p. at 20 m.p.h., and even at that the petrol consumption is high, while the oil is terrific. If he does not believe me I refer him to the various letters early in 1914 on the cost of running. In the officially-observed trial of the Clyno and sidecar in 1914, carried out, according to your report, in bad weather, heavy roads, and strong head winds, the oil consumption was 504 m.p.g. If "Ixion" has based his figures recently on an actual machine, we must surely look there to find the freakishness, for I am sure they are not the figures for average machines, though big "revs." do not spell economy. AC 154.

Nuneaton.

LAMINATED SPRING FRAME.

Sir,—I beg you to set the minds of Messrs. Baker, Ltd., at rest. My design was not patented, because at the time I first considered it I was in France; but I sent it because I thought it might be of interest to your readers. Therefore, Messrs. Baker, Ltd., have no further need to worry.

(Pte.) A. F. MARKHAM.

PETROL AT EASTER.

Sir,—A friend of mine informs me that there is a movement amongst motorists to allow them to use petrol that they have in stock for pleasure this Easter holiday. A great many motorists still have a supply of petrol and substitute by them, and would be glad of a little recreation in these hardworking times, especially those engaged on munitions and shipbuilding. For one thing, it would enable them to travel to their homes more comfortably than by a crowded holiday train and restricted railway service; and a little of their holiday could be spent in the pleasant country, enabling them to return to their work much refreshed for further exertions. The Government is asking for money for War Loan, so I think this would be a good way to get it, as I suppose the Inland Revenue taxation money could be claimed for war purposes. R.W.W.

Stockport.

[We have already stated that, so far as we are aware, there is no truth in the rumour.—Ed.]

SIMPLE TYPE CARBURETTERS.

Sir,—I do not know if "Chinook" has tried the carburetter design he describes in the last issue, but I have. Somewhere about 1901 I protected a very similar design, and rode a motor bicycle fitted with it. The control was the same, also the working of the needle valve and arrangement of the thin mushroom diaphragm. The only difference in my carburetter was the absence of a flooding device, and the control of the top rod was by screw instead of a cam.

This carburetter gave very good results up to a certain point. Its main fault was that the petrol feed was too sensitive. For instance, supposing one were ascending a hill, and more power were wanted, the needle valve was opened, and this was always followed by a rush of petrol, which upset the mixture. A very slow thread control was then tried. This proved better, but it still required very delicate manipulation, and was finally abandoned in favour of a float fed jet as being more certain in action.

I do not think every carburetter maker would employ a float chamber and float if the extra expense and complication could be avoided.

I believe in a variable jet carburetter, either by needle or otherwise, in conjunction with a float feed, but nicety of control will be difficult to obtain without a float feed and a throttle.

One drawback of the simple form of carburetter suggested by your contributor is that the engine cannot be made to run slowly. This may not matter so much in the case of a two-stroke. My experiments were made on a four-stroke, and there were practically no intermediate speeds possible with this type of carburetter. You will readily see that the diaphragm needle and spring have to be very light to respond to small differences in atmospheric pressure. When they are made light enough to do so, they are so fragile that they are hammered out of shape in no time.

When the engine was stopped, the main petrol tap would always require to be closed. No spring-controlled needle valve would hold the petrol unless the spring were so strong that the engine suction would barely lift it.

I hope these experiences will be of some use to "Chinook" and others. EXPERIMENTALIST.

ANOTHER LIGHTING PROBLEM.

Sir,—May I beg a little space in the "Blue 'Un" to express my sincere thanks to those of my fellow readers who have so kindly replied to my letter *re* wiring a solo mount, in your issue of February 7th, thereby getting me out of the difficulty. The designs seem easy and efficient, and I shall try them at the first opportunity.

I am, however, a little puzzled over the following, and would esteem it a great favour to have a further explanation: How does "Allon" get his variable light, and how can I get the same with my ordinary fixed lamp socket? I could convert my holder to take the bulb he mentions. Will Mr. Wilberforce Durell tell me what is one ohm resistance? Would the same current be used with resistance thrown in as with it out—in other words, would the resistance use any current? A diagram of how the one ohm resistance and key switch could be easily made, what sort, and how much wire to use would be gratefully accepted. Mr. S. I. Heale's letter I perfectly understand, except the eight to ten ohm resistance, which I trust to have explained.

(Sec.-Lt.) R. PERCY, R.F.C.

["Electricity and the Motor Car," by Hutton, will explain all these difficulties.—Ed.]

RESPECTIVE PETROL CONSUMPTIONS.

Sir,—Surely "Ixion" is a little off the lines in his figures for petrol and oil consumption. At the outset he appears astonished that the aero engine registers a better figure for "pints per b.h.p. per hour," working on practically full load, than the motor cycle engine on an average throttle opening of about one-third. I should have thought that it was practically universally known and appreciated that running on anything less than, say, threequarters full load was comparatively wasteful of fuel. The heat efficiency of any internal combustion engine is not good at light loads. I venture to suggest that a well-designed motor cycle engine will register practically as good a figure for "pints per b.h.p. per hour" at seven-eighths full load on the test bench as an aero engine also at seven-eighths full load on test under similar atmospheric conditions.

"Ixion" shows that whilst the aero engine registers .54 pint per b.h.p. per hour, the motor cycle engine does very little worse, viz., .66 pint per b.h.p. per hour; and I would suggest that he is comparing an aero engine almost fully extended and at its most economical r.p.m. with a motor cycle engine on about two-thirds load.

In the case of his light car of 10 h.p., he is surely "miles" out with a figure ".4 pint per b.h.p. per hour." No reasonably built light car requires an output of 10 b.h.p. to drive it at 20 m.p.h., on practically level roads as an average, to give 40 m.p.g.

The average output might be 5 b.h.p. to give an average of 20 m.p.h. over sufficiently easy roads to obtain a consumption of 40 m.p.g. An efficiency figure of ".8 pint per b.h.p. per hour" would be about correct and in accord with actual tests. If the same light car engine were tested on the bench at seven-eighths full load at, say, 1,800 r.p.m. it might register ".56-.6 pint per b.h.p. per hour." It might then be developing about 16 b.h.p.

A damaged aeroplane being taken for repairs after a bombing expedition.

MOTOR CYCLING FOR THE MAIMED.

Sir,—As a regular reader of your valuable paper, I have ead considerable correspondence *re* "Motor Cycling for the Maimed." I have faint remembrance of letters from various of your readers, some considerable time back however, of machines adapted for the use of riders who have lost a hand. I am afraid my memory is not so good as it might be, as I have quite forgotten what alterations were made; probably I did not make careful note, as I was sound in wind and imb in those days. All late correspondence on this matter appears to deal only with those unfortunates who have lost egs. I wonder if any of your readers can perhaps help me and probably others who have now lost their left hand. I, personally, for the sake of simplicity, favour the 4¼ h.p. single combination with three speeds, kick start, and hand-controlled clutch—rather a problem to get over. I do not know what difference an artificial hand would make in case of control of such a machine. Certainly a machine of the Enfield type would lend itself more readily to conversion; the gear, for instance, could no doubt be operated by the old heel and toe method, as used in clutch control. But then you are faced with the difficulties of starting, insomuch as it (the Enfield) is hand started, and I do not quite see how the exhaust valve lifter is going to be worked.

ARTHUR V. BURTON.

Sir,—As a constant reader of your valuable paper for the past nine years, in New Zealand, France, and England, perhaps I may be permitted to air my views on one or two of the much-discussed subjects of the moment.

I have owned seventeen motor cycles, a Carden monocar, and a G.N. cycle car since first bitten by the motor "rabbit," so have had a fair chance to form an idea of the "ideal" motor cycle—if such a thing exists.

As regards "motoring for the maimed," in this hospital we have four motor cycles owned by men with one leg, and I recently disposed of the second machine I have owned since disposing of my left arm in France, last June. We all ride standard machines—Rover, Humber, Rudge-Multi, and Bradbury—the only alterations needed being for the legless riders, who fit a hand lever (as per Indian clutch control) to the foot brake or clutch—depending, of course, upon which leg is missing. We all use sidecars as a rule, but often have a run solo, with more or less luck as regards spills. Personally, I find it just as easy to manage any of the machines, with sidecar especially, as it was with two arms.

As regards machines for the Colonies, may I, as a keen rider having no connection with the trade in any way, put a question to home manufacturers, viz.: "Can they expect to turn out their 3½ h.p. singles or 8 h.p. twins (guaranteed to shake the 'innards' out of anybody, not made of cast iron and rubber, over ten miles of back-country N.Z. roads) to be in the same street with the spring-frame Indian, whose many merits are too well known to need detailing here?" Well, till they do, the Yankee machine will certainly hold precedence with most of us who have tried both. Hoping you will pardon the length of this discourse, and wishing you the success you well deserve,

Weybridge. NEW ZEALANDER.

ROTARY ENGINES FOR MOTOR CYCLES.

Sir,—I receive *The Motor Cycle* out here every week; it is most popular with the troops, especially with those who have anything to do with motor cycles.

I agree with "Ixion" on the absolute futility and madness of thinking of applying a rotary engine to a motor cycle. A rotary engine is a horrible affair, and only suitable for one purpose, *i.e.*, where high power is needed at a very small weight and space, and where no restrictions are placed on fuel and oil consumption and time spent on overhauling. It would be a fearful affair decarbonising and keeping in repair a multi-cylinder rotary engine when reduced to the tiny size it would be for a motor cycle. Incidentally, too much comparison has been made between aeroplane and motor cycle engines lately. They do not work under anything like the same conditions. Also it is ridiculous to compare the power to weight ratio of an aeroplane engine of, say, 200 b.h.p. with that of a motor cycle, which would be 10 h.p. at most! Any engineer knows that the weight per horse-power grows rapidly as the engine size diminishes.

B.E.F. R. BAMSELL.

A POST-WAR IDEAL.

Sir,—I should like to express my opinion as to the mount I should most favour if it were upon the market, and that is a large single two-stroke. I have been an enthusiast of the two-stroke for some time, and have longed for a machine to be made something after this style: Horse-power 4¼ (or thereabouts), single two-stroke engine, like the Radco as regards simplicity and efficient running; Zenith-Gradua countershaft gear, giving ratios from about 4½ to 10 to 1; Triumph frame with Radco spring forks; Rover silencer; T.T. handle-bars, celluloid covered, like the Enfield. This would be my ideal, and I should like to hear of any criticisms and views on a cycle like this; also of anybody who may be looking for a mount something after this style.

London, N. J. A. JEAPEZ.

Sir,—It is to be hoped that when manufacturers are considering new types to be produced after the war they will not sacrifice efficiency to cheapness, on which latter consideration so many of your contributors lay such stress. There are many buyers who would gladly pay £10 or £20 additional for a reliable, comfortable machine, with plenty of power but of moderate speed, easily controlled and started, and capable of being driven at a walking pace.

Just prior to the war, for reasons of health, I took a house in the country, at an elevation of 500 feet, about ten miles from my place of business, without any railway communication. For three years my Panhard car has taken me to and fro daily without trouble. I drive myself in each morning and back each evening. My consumption of petrol was about thirty gallons per month. This convenient arrangement lasted until my petrol allowance was reduced to ten gallons per month.

It is no easy matter, when one has passed sixty, to make a new departure, and, against the warnings of all my friends and family, I determined to try a motor cycle, having been a rider of the push bicycle from the far-off days of the iron-tyred boneshaker. My first venture was a 3 h.p. two-cylinder machine, which ran delightfully when it did run, but was constantly in dock for trivial breakages, which was most annoying and expensive. Recently I was fortunate enough to come across a new 3½ h.p. single-cylinder Rover, which has given me no trouble at all, and I now run in and out daily with the same regularity that I was accustomed to on my car.

The pleasure of riding a motor cycle, solo, is so great that after the petrol restrictions are removed I shall probably continue to use the cycle when weather permits. The cost of a motor cycle, when compared with a car, is so small that one can easily afford any reasonable addition to the cost to get additional comfort. I should like my clothes to be protected from oil and the machine from mud. It would be a great advantage if the clutch could be controlled by hand as well as by foot. Less noise when the engine is running with the clutch out would be pleasant. The three-ribbed tyres fitted to both machines have proved quite satisfactory, and I have not had the semblance of a side-slip. The simplicity of the single-cylinder machine, when combined with the chain-cum-belt drive, appeals to me, and the admirable Brooks saddle appears to absorb all vibration, if there is any. SENEX.

Bridgwater.

STANDARDISATION.

Sir,—Being an interested reader of your paper, I have noticed several times articles on "Standardisation." I think the idea is all right, as regards small fittings of machines, but I hardly think the subject will be a success with complete machines. No doubt "standardisation" is *the* thing as a war measure, but it is to be hoped that after the war firms will continue with their original designs. I think we may take it for granted that a standard machine would be much cheaper, owing to quantity production, but the crux of the matter is that scarcely two riders have the same opinion of one machine. Again, makers have innovations on their machines which they will not willingly scrap; also, with standardisation, initiative would tend to become stagnant.

At present, in England, our people seem to be "standard mad"—clothes, boots, food, and everything generally. Let us hope that, after the war, one will be permitted more freedom of action, and it is then we shall see the results of original designs, which have been on the drawing boards so long. SAPPER.

QUESTIONS & REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Magneto Voltage.

? Will you please let me know the voltage of a high-tension magneto?—B.W.G.

The maximum voltage of a high-tension magneto varies from 7,000 to 10,000 volts, depending upon the strength of the magnets, the number of revolutions per minute, etc.

Altering the Lubrication System.

? I purpose putting a copper pipe from my oil pump to the crank case. Do you think it advisable to bore a $\frac{5}{16}$in. hole in the crank case? I do not care for the petrol-oil system. My motor cycle is a $2\frac{3}{4}$ h.p. two-stroke fitted with an Armstrong three-speed hub gear. There is already a pump fitted, but the measure has been lost. Do you advise me to fit this as I suggest for lubricating the engine, and where should the hole be bored, and what lubricating oil should I use?—R.A.S.

There is no reason why you should not tap your crank case in a suitable place and fit a union, so that you can fix a pipe and oil directly into the crank case, or allow a constant supply to be maintained therein through a drip feed. The hole should be preferably high up in the crank case, where there is plenty of metal. A good brand of air-cooled engine oil should be used.

Cracked Valve Seating.

? I have a Morgan with 1914 A.C. 8 h.p. J.A.P., and find that one exhaust valve guide is cracked (at the top inside cylinder). I want to remove this. It is evidently screwed in, and I am expecting to find it very tight. Would you advise soaking round it with paraffin or heating with a blow lamp? In this case, I presume, one would heat the cylinder around the guide. The valves also are very pitted. Is it better to send them to the makers to be refaced? I do not think I can ever grind all the pits out. —G.T.D.

If the valve guide is too tight to be removed by direct unscrewing, you should try soaking it well with paraffin, and only when this has failed try a blow-lamp. If you have to use a blow-lamp, heat the cylinder around the guide, and take care that the guide itself does not become heated, otherwise the guide also will expand, and, of course, there will be no advantage. Any good mechanic should be able to skim up the valves of your engine on a lathe, and there is no need to send them to the makers.

An Allotment Holder's Queries.

? I wish to alter my $3\frac{1}{2}$ h.p. Humber and sidecar so as to come under the free-of-duty trade requirements. (1.) How will this affect the registration of the machine? I fitted the sidecar since registering the machine. (2.) I propose to use this machine for taking tools and stuff to allotments which I have, and also for the benefit of my friends who have allotments. I have thirty rods under cultivation myself, and last year the machine was very useful for transporting soot, manures, and tools, and conveying produce home. When not required for this purpose it will very likely be lent to a local tradesman for the transport of goods. I purpose putting on the carrier my name and address and occupation, say allotment holder, or would it be better to put engineer, which is my real occupation? (3.) I propose to run the machine on coal gas, mainly with a little paraffin as a stand-by. I suppose I should have to obtain a gas permit. The machine has been run on paraffin for the last two years, including some long runs, and I still have about six gallons of petrol left from my allowance.—T.W.S.H.

(1.) We think your best plan would be to write to the local registration offices and explain to them just what you are doing with regard to your machine. We do not think it will be necessary for you to do more than this. (2.) It really does not matter what line of employment you mention on the sidecarrier. Only your name and address are essential, painted in letters not less than 1in. in height. There, however, may be some difficulties with the police if you loan the machine to other tradesmen. (3.) You will have to write to the Petrol Control Department, 19, Berkeley Street, London. W.1, for a permit to run on coal gas, stating for what purposes you intend to use the machine. Also you may not run the machine on any liquid fuel without a permit.

THE LIMIT IN PASSENGER CARRYING.

A four-passenger sidecar attached to a Reading standard. The scene is in the Italian Alps, at a height of several thousand feet.

(*"Motor Cycle and Bicycle," New York.*)

Hints on Maintenance.

(1.) What is the best substance known to you for cleaning rust off the rim of a wheel? (2.) Do you know anything better than aluminium paint for putting on rims so as to give a bright finish? (3.) Are soldiers on leave allowed to use a motor bicycle? (4.) Is vaseline satisfactory to put on rims after they have been cleaned?—W.S.D.

(1.) There is nothing better than coarse emery cloth. If the rims are plated, petrol is some use; but if they are in bad condition, there is nothing that will clean off the rust which will not also remove the plating. (2.) Aluminium paint is satisfactory, and we do not know of anything better than this for the purpose. (3.) Yes; provided application is first made to the Petrol Controller's Department, 19, Berkeley Street, London, W.I, for a permit, which is, however, granted only to soldiers on leave *from one of the fronts.* (4.) After the rims have been cleaned of rust they should be painted, preferably with black paint. If vaseline is applied t should only be used on the bright part, and must not touch the tyres.

The Effects of a Plug Adapter.

I have a lightweight motor cycle of about 1¼ or 1½ h.p. (1.) After two miles or so it will overheat and misfire very badly—in fact, sometimes it even comes to a standstill. The compression is poor. There is an adapter on the top of the cylinder to take the plug, which leaks. Do you think this would cause the trouble, and why is the adapter necessary? The adapter is L shaped and screws into the top of the cylinder. If it were not fitted the plug points would project into the compression space inside the cylinder. Do you therefore think it is really for "pocketing" the plug? (2.) The engine is fitted with an automatic inlet valve. What strength of spring should I use, and what is the correct lift? (3.) What size of carburetter jet should I use (B. and B. old pattern)? (4.) When I accelerate on the road or on the stand the engine seems to choke up, and starts to misfire badly. What is the cause of this? (5.) The magneto is driven by a skew gear on the flywheel, and there is an arrangement for shifting the armature backwards or forwards to get the advance and retard. What is the proper timing for this class of machine? (6.) What speed should this cycle be capable of on a run of, say, thirty miles? (7.) I wish to remagnetise the magneto. A friend of mine tells me I can do this quite successfully with a battery. I have got a four volt accumulator, but I should imagine I would also require some sort of coil. Please let me know if I can remagnetise the magneto myself.—R.W.W.

(1.) The adapter might well cause misfiring due to leakage. We do not think one should be necessary unless it was to take a special plug for which there was not sufficient clearance in the ordinary way, and undoubtedly the adapter causes pocketing. We should think there would be no difficulty in getting a small size plug. (2.) The lift should be about $\frac{3}{32}$in., and the strength of the spring should be such that when the valve is shaken violently in the hand it should only just open. (3.) We should think that a .026 jet would be about the size. (4.) Probably too large a jet is fitted. (5.) The timing is the same as for any other small machine, namely: Place the piston exactly on top of the compression stroke and connect up the magneto with the points just about to break and the ignition lever fully retarded. (6.) About 18 m.p.h. if the roads are fairly flat. (7.) We fear you cannot remagnetise the magnets yourself, and certainly not with a battery.

An Unsatisfactory Exchange Deal.

Some weeks ago I advertised my Rex combination for sale, or exchange for lower power. I received a reply from a person offering me a 1913 model Premier, and came to terms, provided the machine were in good running order. When the machine arrived I could not start it; I have tried several times. I at once wrote to the vendor telling him I was dissatisfied with the bicycle, and asking him to return my combination, as I was not pleased with the looks of the bicycle. I thought it was an earlier model than he stated. I wrote to the makers, and they informed me it is a 1910 model (the man stated it was a 1913). What course should I take to procure the return of my own machine?—J.C.

Your course of action should be perfectly clear and straightforward. Write to the man who has your machine, demanding its return, and stating that if you do not hear from him within a certain time you will be compelled to put the matter in the hands of a solicitor. You will have no difficulty in obtaining the return of your machine through a court of law.

Accumulator Queries.

Will you please give information on the following? I have bought a set of four accumulators for lighting my combination. (1.) How can I tell the voltage and amperage, as they are not marked on the cases? Each accumulator has four grey and three brown plates. (2.) At what rate should they be charged when connected in series in a case?—J.W.

Each cell of an accumulator gives, when fully charged, 2.2 volts; consequently the total voltage of any accumulator is 2.2 multiplied by the number of cells. The ampère hours can only be obtained from actual test, viz., if you connect the accumulator to a lamp of the same voltage as the accumulator the number of hours that the lamp is fully lit multiplied by the ampèrage of the bulb will be the capacity of the cell. It is impossible to give the charging rate without knowing the rate of discharge; consequently, your best course is to charge the accumulator at a fairly low rate, say from .5 to 1 ampère, until the accumulators show by frothing and by the reading of the voltmeter that they are fully charged.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY.

During 1918 the restrictions on the import of paper and paper making material are very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week.

Repairing Petrol Tanks.

(1.) I have read on several occasions in your "Questions and Replies" column, when you have advised readers as to the best means of finding leakages in petrol tanks, that you have also advised them to get the soldering done by an expert, owing to the great danger. Now what puzzles me—and this is my first question—is wherein does the danger lie, provided the tank be empty? (2.) Please tell me the best way to remove the belt rim of a modern B.S.A. big single chain-cum-belt drive, in order to replace broken spokes on that side of the driving wheel.—D.C.

(1.) The danger is in soldering the tank when it contains petrol vapour, which may remain after the petrol is emptied out of the tank. We had a large tank to solder one day last summer, and drained it carefully, leaving it to dry in the sun all day. We then found it could be soldered with perfect safety that evening. (2.) So far as we can recollect, the belt rim is spoked on to the wheel. If this is the case, the short spokes holding the belt rim must be removed. In replacing the belt rim great care should be taken to see that it is true. See also "A Reader's Reply" on this subject in *The Motor Cycle* of February 21st.

EXPERIENCES WANTED.

"A.V.B." (Slough).—Abingdon King Dick engine and Wolf combination. Reliability, etc.

RECOMMENDED ROUTES.

LEEDS TO YARMOUTH.—H.P.
Leeds, Pontefract, Doncaster, Retford, Newark, Sleaford, Swineshead, Long Sutton, King's Lynn, Swaffham, Dereham, Norwich, Acle, Yarmouth.

CARLISLE TO GLOUCESTER VIA BLACKBURN.—H.B.
Carlisle, Penrith, Shap, Kendal, Lancaster, Preston, Blackburn, Bolton, Warrington, Tarporley, Whitchurch, Wellington, Bridgnorth, Kidderminster, Worcester, Tewkesbury, Gloucester.

ASHFORD TO LEEDS.—W.P.
Ashford, Maidstone, Chatham, Gravesend, ferry to Tilbury, Romford, Waltham Cross, Ware, Huntingdon, Stamford, Grantham, Newark, Retford, Doncaster, Pontefract, Leeds.

Catalogues Received.

A well-got-up list of Pedley motor cycle tyres, inner tubes, tyre accessories, such as repair outfits, inflator tubing, Pedley motor-cycle belts and belt fasteners, has recently been published, and a copy may be obtained on application to Messrs. John Pedley and Sons, Ltd., Oxford Works, Great Charles Street, Birmingham.

We have recently received a copy of a new spare and replacement parts list from Messrs. Butterfields, Ltd., of the Levis Motor Works, Stechford, near Birmingham. The list is attractively got up, and anyone interested may have a copy on application.

Gas Filling Station.

We have received a map, scale four miles to the inch, of gas filling stations situated within forty miles of Manchester, issued by Messrs. Brannen and Co., 43, Edge Street, Shudehill, Manchester. Under the name of each town the address of the gas charging station is given, the price of gas per 100 cubic feet, and the hours at which the station is available.

Liquid Fuels.

"Liquid Fuels for Internal Combustion Engines," by Harold Moore, M.Sc.Tech., F.R.C. Crosby, Lockwood and Son, 2, Stationers' Hall Court, Ludgate Hill, London, E.C.4. 12s. As is claimed by the author, the book is more for engineers and chemists than for the average motorist, but there is a good deal in it which cannot fail to enlighten the ordinary reader which is clearly understandable by the lay-mind.

The book deals with liquid fuels for three types of engines. (1.) Engines fitted with carburetters (generally known as petrol motors; these, of course, include motor cycle engines). (2.) Engines fitted with simple vaporisers (generally known as paraffin motors). (3.) Engines fitted with fuel pumps and atomising devices—that is to say, semi-Diesel and Diesel engines. The chief use of the book is that it tells us what fuels may be used in internal combustion engines, how they are made, and of what they consist. It also deals with the important question of fuel after the war, and there seems to be no doubt that the fuel shortage will be with us for a long time after hostilities cease, and, consequently, chemists will be hard put to it to find substitutes for petrol until such time as normal supplies are obtainable.

Dealing with the process of "cracking," which consists of subjecting oil to violent heating in the absence of air, Mr. Moore points out that Mr. W. A. Hall, in the *Journal of the Institute of Petroleum Technologists*, suggests, as a future source of petrol in Great Britain, the production of cracked spirit in specially constructed oil gas plants, to be worked in gasworks, and estimates that motor spirit could be produced as a by-product at a cost of 5d. per gallon.

Mr. Moore also deals with shale oil, coal tars, and their products, benzine, and benzole, the possibility of getting fuel from wood and peat, and from alcohol. Some of the figures given in the book are extremely interesting, and the work is certainly one which might be well studied to the advantage of a large number of users of internal combustion engines.

Repairing Motor Cyclist's Overalls.

Motor cyclists have long experienced the annoyance of torn overalls, and have long realised the impossibility of satisfactorily repairing these garments, whether they be made of macintosh, oilskin, or waterproofed cloth. The Leicester Rubber Co., Ltd., Post Office Place, Leicester, have now brought out a couple of repairing outfits, one suitable for khaki and waterproof materials, and the other a general outfit, which is intended for the repair of coats, overcoats, waistcoats, trousers, linings, oilskins, hoods, umbrellas, and kid gloves. Both these outfits are sold under the name of Mend-a-Tear.

To mend a tear in a garment it is better to repair from the inside. From a strip of material found in the outfit a patch large enough to cover the tear properly should be placed over the part to be repaired, coated side downwards. It should be then covered with a piece of paper and an ordinary hot flat iron should be applied to it. In repairing a lined garment the patch should be inserted through the tear, coated side upwards, and then treated with the iron after a piece of paper has been applied. To repair very thick material, roll a narrow strip of Mend-a-Tear adhesive to about the thickness of a pin, and insert this between the frayed edges of the tear in addition to the patch.

It is also possible to repair a garment with a piece of the same material, which, of course, is an undoubted advantage.

The outfits cost 1s. each.

(Left) A torn garment before treatment. (Right) The same garment half-an-hour later.

Review.

"The Aviator's Handbook," 1s. 6d., L. M. Waterhouse, M.I.E.E., M.I.A.E., A.M.I.C.E., and H. Arrault, A.F., Aero Institute, Engineer in Aeronautics. The Aeronautical Department, the Motor Training Institute, 10, Heddon Street, Regent Street, London, W.1.

In view of the interest taken by this journal in aviation, the booklet that we have under review will be of undoubted value to those of our readers who are following up the subject. It is exceedingly handy for them to have at their disposal a concise dictionary of flying terms to which they may refer, and so quickly master the subject which they have taken up. The English-French and French-English dictionary of aviation terms, one printed in red and the other in blue, will also be of great value. There is much in common between the aviator and the motorist, especially so far as the engine and also tool and shop terms are concerned.

British Magnetos.

"About British Magnetos"; published by the British Ignition Apparatus Association, 8, Breams Buildings, London, E.C.4. It is stated in this brochure, which contains an interesting history of the development of the British magneto, that the number of these instruments constructed in this country at the beginning of the war was quite small, owing to the fact that the Germans were first in the field, and had established a reputation for a well-made article. To compete against this reputation would have meant much hard work, and also the outlay of much money, and in spite of warnings published, chiefly by *The Autocar* and *The Motor Cycle*, manufacturers did not think it worth while to expend money or work in connection with the manufacture of an instrument which possibly might not prove a success. The war has altered this state of affairs, and there are at the present time nine firms engaged in the manufacture of magnetos, whose works are all illustrated in the centre of the booklet. The difficulties with which British magneto makers had to contend were great, and entailed much research work, the procuring of special materials, and also the task of learning the special processes necessary.

The nine firms in question are members of the Association, and much of the success gained is due largely to the opportunities afforded by the Association to its members for co-operation and interchange of ideas. The magnetos produced by these firms will be standardised; the complete magnets are to be made interchangeable with the best pre-war types, as well as with one another; most of the essential parts are to be standardised and made interchangeable; for example, screws will be of standard dimensions, different sizes of brushes are to be standardised and reduced in number, and therefore spare parts will be cheaper, more easily made, and quickly obtainable.

The book deals also with the work carried out by the Tanks, aeroplanes, airships, and motor patrol boats fitted with British-made instruments, and concludes with an illustrated list of the standardised types of British magnetos for the motor trade.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

7h.p. Matchless M.A.G. 6B. Combination, with Swan sidecar, hood and screen, £55; another, with Matchless sidecar, hood and screen, £65; brand new 8B2 combination, M.A.G. engine, spare wheel and tyre, £125.—1a, Bloomfield Rd., Plumstead. [X2783

MATCHLESS 1917 8B2 Combination, run 450 miles, condition as new, and mechanically perfect, fitted wind screen, leg guards, footboards, despatch box, tool cases, 2 Lucas 462 head lights, generators complete, tail light and generator, Enk easy starter, watch, Cowey trip speedometer, mirror, Lucas horn, spare wheel and tyre, petrol carrier and can; cost £160 last September, will accept £135; seen by appointment.—A.T., 9, Shirley Rd., Wallington. [X2742

New Hudson.

NEW Hudson, 1913 pattern, 2½h.p., lightweight, easy running machine; £20.—Box L5,804, c/o *The Motor Cycle*. [4024

NEW Hudson, 1914, 4h.p., 3 speeds, coachbuilt sidecar, in first-class condition; £34.—Percy and Co., 337, Euston Rd., London. [4167

RIDER TROWARD and Co., 31, 40b, 78, High St., Hampstead.—1915 New Hudson Big Six combination, 52 gns.; 1916 New Hudson, 2-speed, 2-stroke, 25 gns. (D) [4092

3½h.p. New Hudson (1914), Armstrong 3-speed, clutch, new gears, bushes, rings, and valves, re-enamelled green, everything perfect; £20, lowest.—Becks, 21, Victoria St., Norwich. [X2784

New Imperial.

CROW Bros., Guildford.—New Imperial, latest 2½h.p., 3½h.p., 6h.p. models in stock; also sound second-hands [1047

NEW Imperial-Jap, 8h.p., 3-speed War Model combination; 109 gns.; delivery from stock.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter. [3521

NEW Imperial-Jap, 2¾h.p., 1916, 2 speeds, lamps, horn, etc.; £24, or nearest offer; must be cleared, owner joining up.—Lethermans, Croft, Dunmow, Essex. (D) [4010

NEW Imperial Motor Cycles, 2 speeds, clutch and kick starter, and lady's models in stock for immediate delivery; trade supplied; no permits required.—P. J. Evans, 91, John Bright St., Birmingham. [3714

Norton.

NORTON 1918 Military Model, brand new, in stock.

NORTON 1916 Big 4 Combination, practically as new; £65.

NORTON, 1917, T.T., indistinguishable from new; £55.—Percy and Co., 337, Euston Rd., London. [4155

NORTON Big 4, all-chain drive Military Model; £82.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter. [3524

NORTON Latest Military Model, Big 4, all chain; immediate delivery; £82.—Parker's, Bradshawgate, Bolton. [X2860

We hope to offer a Special Bargain each week this year

THIS WEEK'S BARGAIN:
Latest Model T.T. Rover, with Philipson pulley, slightly shop-soiled, absolutely new; engine has never been started up.
55 gns. only.

Send for List of Machines, including

MOTOR CYCLES FOR SALE.

Norton.

RIDER TROWARD and Co., 31, 40b, 78, High St., Hampstead.—1918 Military Model Norton, new; £82. (D) [4078

NORTON.—Big 4 Military Model, all-chain, new; also chain-cum-belt, £57 10; E.P., or exchange.—Service Co., 292, High Holborn, London. [X2847

3½h.p. Brooklands Special T.T. Norton, winner of Public Schools' hill-climb; owner at sea; £45.—W. P. Cubitt, H.M.S. New Zealand, c/o G.P.O. [X2828

N.S.U.

N.S.U., 2¾h.p., just overhauled, Bosch speedometer, splendid running; about £17.—F.W., 50, Guilford Av., Surbiton. [3988

HAVING Acquired the entire stock-in-trade of the N.S.U. Motor Co., Ltd., we can supply spares for practically all types of N.S.U. motor cycles. In ordering it is important to submit old parts as patterns.—Eagles and Co., Acton Hill Works, Acton, W.3. [0739

N.U.T.

3½-4h.p. N.U.T., twin-cyl., belt drive, 3 speeds, 2 brakes, kick starter, Lucas head lamps, knee-grips, horn, all accessories; a bargain, £55, lowest, in new condition.—Miller, 62, Hampstead Rd., N.W.1. [3927

Premier.

PREMIER, 3½h.p., Gradua gear, in splendid order, take sidecar anywhere; £15.—16, York St., Dover. [4172

RIDER TROWARD and Co., 31, 40b, and 78, High St., Hampstead.—1916 military model Premier, 3½h.p., 3-speed; 42 gns. (D) [4095

PREMIER, 1914, 3½h.p., 3-speed, P. and H. lamp, horn, Stewart speedometer, etc., £23/10; 1916 3½h.p., 3-speed countershaft and kick starter, coach built sidecar, large P. and H. lamp, horn, £61/15; E.P or exchange.—Service Co., 292, High Holborn, London. [X2846

Quadrant.

QUADRANT Combination, 1915-16, 4¼h.p., B.S.A. 3-speed gear box, chain drive, specially sprung coachbuilt sidecar, mileage 1,000, condition as new; £52, lowest.—Graves, Harlington, Middlesex. [3987

Radco.

RADCO, 1915, 2-speed, 2-stroke, 2¼h.p., good appearance; £21/10.—Motor Exchange, Horton St., Halifax. [4034

Rex.

REX, 3½h.p., battery, £7, or exchange 8h.p. w.c. single engine, cycle car parts.—40, Clarendon Rd., E.17. [4005

MOTOR CYCLES FOR SALE.

Rex.

RIDER TROWARD and Co., 31, 40b, and 78, St., Hampstead.—1914-Rex 6h.p. coach com tion: 38 gns. (D)

1912 Rex, 6h.p., 2-speed gear, cane sidecar, in condition throughout; £28/10.—J. Plastow, Osborne St., Grimsby. [X

REX, 1913, 6h.p., 2-speed, sidecar, just overha suit tradesman; bargain.—Rogerson, 9, H Hall Rd., Newcastle-on-Tyne. [X

REX de Luxe 1914 3½h.p. Combination, Bosch tight mag., B. and B. carburetter, tyres mechanically perfect; £20, or offer.—93, Fentiman London, S.W.

REX, 3½h.p., Binks 1916 3-jet carburetter, mag., lamps, horn, new John Bull belt, new shall back tyre, good condition; bargain, £15, or —Box 1,787, c/o *The Motor Cycle*. [X

Riley.

4h.p. Riley Cycle, B. and B., engine good, ac lator, £5; wanted, N.S.U. gear.—2, Ann Te Brechin. [X

Rover.

ROVER, 3h.p., clutch, 3-speed, new back cover gain, £12.—17, Cobourg Rd., Bristol. [X

1917 3½h.p. Rover, little used, one owner only new; £70.—J. Fryer, Ltd., Hereford. [X

ROVER.—All new models supplied; E.P. or exch —Service Co., 292, High Holborn, London. [X

ROVER, 1913, free engine clutch, Bosch, new lops and tubes; owner joining up; offers 1,790, c/o *The Motor Cycle*. [X

3½h.p. T.T. Rover, late 1917, used 6 weeks, met fatal accident whilst flying, perfect tion; £55.—Mrs. A. D. Stewart, The Heath, Peter Hants.

ROVER, 3½h.p., 1917, with sidecar, new in Se ber, only ridden twice; cost £100; want price £60; seen any time.—Owner, 83, Carleton Tufnell Park N.7.

3½h.p. New Rover Combination, fitted with g Rover sidecar, includes all accessories; £84, guaranteed brand new.—Seen at Wauchop Shoe Lane, London.

ROVER Motor Cycles, 3½h.p. and 5-6h.p. mod stock for immediate delivery, both solo and car outfits; trade supplied; no permits requir J. Evans, 91, John Bright St., Birmingham.

1917 Rover, T.T., Philipson; this machine is tinguishable from new—in fact, it is in condition than a new machine, only done 500 price 50 gns.—Julian, 84, Broad St., Reading. light car and motor cycle dealer in the South 1024. Closed Wednesdays 1 o'clock.

Royal Ruby.

ROYAL Ruby.—All new models supplied; E exchange.—Service Co., 292, High Holborn,

Rudge.

RUDGE Multi, 3½h.p., absolutely tip-top; £23 for particulars.—Box L5,801, c/o *The Motor*

BARGAIN.—1915-16 Rudge Multi, 3½h.p., Rover sidecar, all lamps, tools, perfect con test invited; nearest £36.—102, Perry Hill, C S.E.6.

RIDER TROWARD and Co., 31, 40b, 78, Hi Hampstead.—1915 Rudge, 5-6h.p., 3-speed, sidecar, 48 gns.; 1916 Rudge Multi, 3½h.p., co combination, 44 gns. (D)

1915 Rudge Multi, fitted with 650×65 Dunlop tyres, P. and H. head lamp and generator tools, etc., in excellent order, only used 2 m The North Finchley Motor Co., Woodhouse North Finchley.

Scott.

SCOTT, in perfect order, with Lucas accessor Stewart speedometer, recent model; £48, or offer.—Dents, Stonegate, York.

Singer.

SINGER, 4h.p., free engine model, Bosch, B., good condition; £20, or exchange ligh —85, Revelstoke Rd., Wimbledon Park, S.W.

Sun.

1915 Sun-Villiers, new condition, perfect, 2 years; £14/10, no offers.—69, Kingst New Malden.

SUN-VILLIERS, 2½h.p., 2-speed countersha £37/16; V.T.S., single speed, new, £30/1 2½h.p., 2-speed, £28/10; E.P. or exchange.—Ser 292, High Holborn, London.

Sunbeam.

1917 3½h.p. Sunbeam Combination, Lucas la horn, perfect condition; £80.—Skiner, Na Leicester.

RIDER TROWARD and Co., 31, 40b, 78, Hampstead.—1916 Sunbeam, 3½h.p., 3-sp fect; 65 gns. (D)

SUNBEAM 1917 3½h.p. Combination, run 6 fully equipped, indistinguishable from ne —Percy and Co., 337, Euston Rd., London.

Joint Research and the Motor Cycle.

II.—How it should be Financed and Conducted.

It may be asked why this particular moment is chosen as an appropriate one in which to raise this question of research and to devise schemes for co-operation in this matter. The answer is simple. We have got to solve the problem of keeping our industries in the forefront after the war. Diversion to war work has handicapped them seriously, and everything must be done to make up lost ground. The Government, recognising the position and the importance of research work as a means of accelerating improvement in design and construction, has created a fund to assist those industries that are willing to help themselves. This fund of £1,000,000 is to be dispensed by the Department of Scientific and Industrial Research during a period of five years. The Department has decided to spend it by subscribing annually to Research Associations which are constituted and regularly supported by their industries. Up to a fairly substantial sum, the Government will put up pound for pound.

It is important to note that this will only be done if the manufacturers' share is made up of regular subscriptions guaranteed for a period of from three to five years. It is felt that the value of research cannot be proved in a few months. Thus if Government support is wanted, it is no good for manufacturers to put up a trifling sum by means of subscription and then to add to it by donations to go to specified researches.

If £2,000 a year were regarded as a reasonable total, and if fifty firms supported the movement, then the average subscription would be £40 a year. This average might be obtained by a sliding scale of subscriptions, under which the biggest firms would pay, perhaps, £100 and the smallest, say, £20 or only £10. These amounts are not in themselves excessive, if the results are likely to be of any great value, but arrangements have been made which improve still further the generous offer that the Government has made. The manufacturers' subscription to a Research Association is regarded as expenditure out of income, before the assessment of income for any kind of taxation. Consequently, with income tax at 5s. in the £, a quarter of the manufacturer's subscription really comes from the Government, inasmuch as it is lost to the Income Tax Commissioners, and threequarters of the subscription is the out-of-pocket expenditure by the manufacturer. Thus a large firm would be expending, out-of-pocket, about £75 a year, possibly 80% of which might otherwise go, as excess profits, to the Government.

From this it will be seen that it is possible now for the industry to start important research on quite a substantial scale and yet at very moderate cost. If the Government is so confident as this in the value of the results to be obtained, surely the industry need have no hesitation in doing its share.

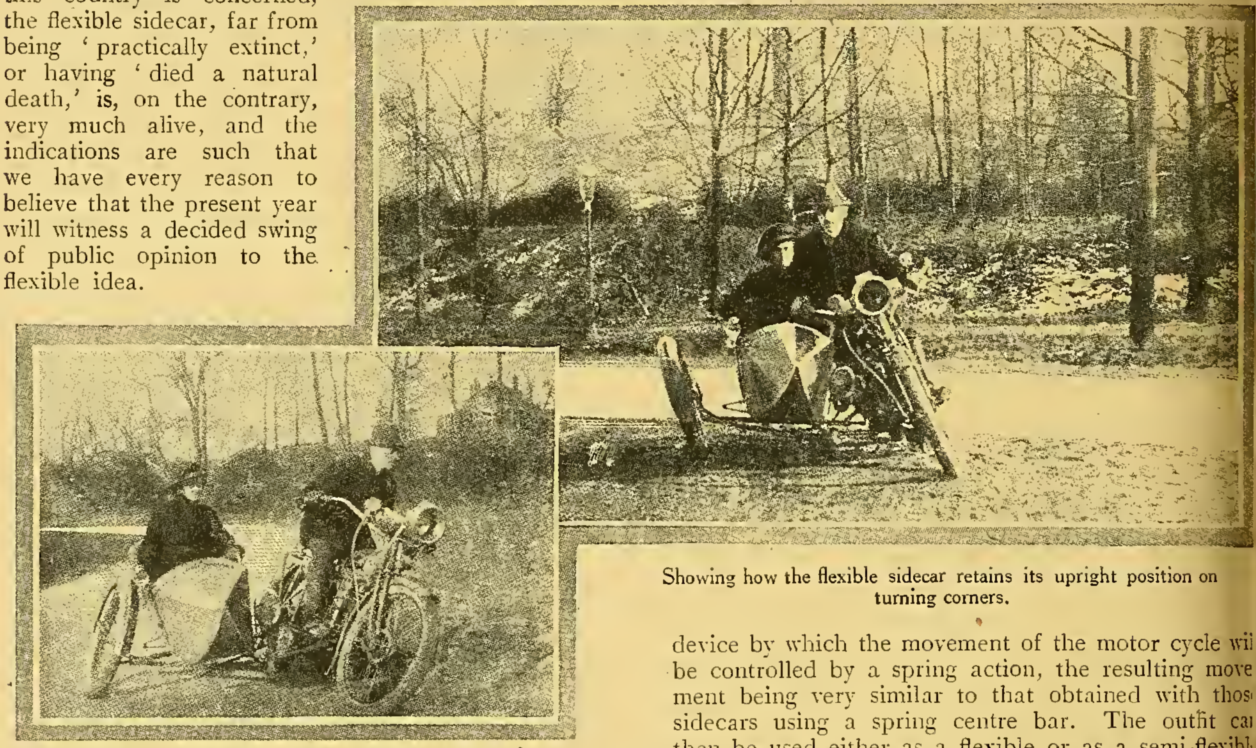
The Government contribution, of course, will be contingent upon the constitution of the proposed research association being satisfactory. The main point on which the Research Department would probably insist would be that the Association should employ a well qualified official as Director of Research. The Director of Research would examine the various proposals put forward by members of the industry, and would advise the Association as to the shaping of its programme, and would supervise all the work put in hand. The Department of Research might also want some small representation on the Board or Council of the Association. The control of the business would always be left in the hands of the industry, and the Government would not interfere with, or dictate to, the manufacturer. The whole proposition is an extraordinarily generous one, and those industries which do not act promptly may find the official funds so far pledged as to reduce very materially the support that can be offered to them.

THE FLEXIBLE SIDECAR IN AMERICA.

Remarks on a New Pattern Sidecar Chassis and on Flexible Sidecars in General.

"ON page 62 of the January 17th issue of *The Motor Cycle* there appeared, under the caption 'The Development of the Passenger Motor Cycle,' a statement to the effect that the flexible sidecar was no more.

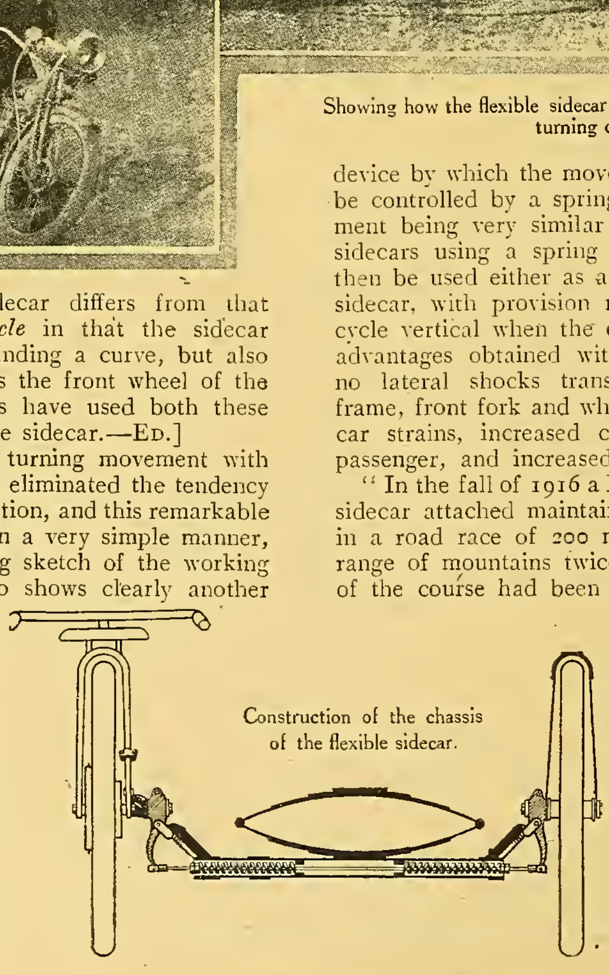
"It may interest readers to know that in so far as this country is concerned, the flexible sidecar, far from being 'practically extinct,' or having 'died a natural death,' is, on the contrary, very much alive, and the indications are such that we have every reason to believe that the present year will witness a decided swing of public opinion to the flexible idea.



Showing how the flexible sidecar retains its upright position on turning corners.

"The present flexible sidecar differs from that described in *The Motor Cycle* in that the sidecar wheel not only tilts when rounding a curve, but also *turns* in the same direction as the front wheel of the motor cycle. [British makers have used both these principles, but not in the same sidecar.—Ed.]

"The combination of the turning movement with that of the tilt has practically eliminated the tendency to side-slip upon every provocation, and this remarkable movement has been secured in a very simple manner, as shown in the accompanying sketch of the working mechanism. The sketch also shows clearly another great improvement over the earliest types of flexible sidecar, that of the adjustable spiral springs housed in the rear frame member, by which the complete outfit can not only be kept in perfect balance, but the side pull or drag on the motor cycle can be perfectly compensated.

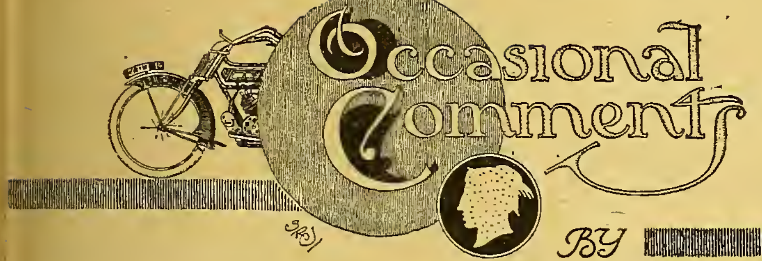


Construction of the chassis of the flexible sidecar.

"The other disadvantage mentioned—that of holding the machine upright when stationary—was overcome by fitting a combination rigid attachment to the sidecar. This was devised solely for the purpose of holding the motor cycle vertically while at rest. It was very easily operated, a touch of the foot or hand throwing on an eccentric lever. An improvement is now being effected in the latter device by which the movement of the motor cycle wi be controlled by a spring action, the resulting movement being very similar to that obtained with thos sidecars using a spring centre bar. The outfit ca then be used either as a flexible or as a semi-flexibl sidecar, with provision made for holding the moto cycle vertical when the outfit is at rest. Among th advantages obtained with this type of sidecar are no lateral shocks transmitted to the motor cycl frame, front fork and wheel are relieved from all sidecar strains, increased comfort for both driver an passenger, and increased m.p.g. and tyre mileage.

"In the fall of 1916 a Powerplus Indian with flexibl sidecar attached maintained an average of 42 m.p.h in a road race of 200 miles, crossing the Alleghen range of mountains twice. Before twenty-five mile of the course had been covered the other competin machine broke the frame o the motor cycle, and afte changing the motor an sidecar to another fram continued on, only to brea the sidecar frame sevent miles further on.

"As will be seen fro the illustrations, the chass is of simple, straight tul design, and all parts are designed that they can used in making up eith right or left hand cars."



Occasional Comment

BY IXION

Oil Consumption.

OUR valued contributor "Engro" takes me to task for supposing that the average oil consumption of a motor bicycle engine is as high as 400 m.p.g. I originally stated that I made this estimate with considerable qualms, but the simple fact is that no standard figure can be given. I myself am a born "scrapper." I learnt bad habits in reporting the early motor cycle trials, when the whole burden of a full report possibly rested on my shoulders, the competitors were travelling at 20 m.p.h., and I had to watch them climb all the important hills, and then catch them up again over bad roads. Under the high average speed thus necessitated, our small big-end bearings heated up in a short time, and had to be oil-cooled. I confess that I habitually ride at speeds which would seize up the big-end, and possibly the piston also, unless I utilised "oil-cooling." Then a comparatively sedate member of the staff tells us that he has owned more than one machine which seldom covered 100 miles without calling for the replenishment of his oil tank; in his case leakages through inferior crank case joints and poorly designed tappet guides were responsible. *Per contra*, I think I remember that Reg. Holloway once rode a 3½ h.p. Premier from Coventry to Town on a single pumpful of oil.

A Suggested Standard.

"ENGRO" makes the interesting suggestion that the simple formula $\frac{\text{Petrol consumption}}{16}$ indicates an average oil consumption, basing the standard on the proportion of petrol to oil recommended by manufacturers for petroil two-strokes. Personally, I consider that a standard can hardly be laid down. Let me give some reasons. In the first place, much of the oil is not "consumed" at all, in the mechanical sense, its consumption being merely economic, as it is ejected through stupidly designed tappet guides and badly fitted crank case joints: a machine of similar h.p. by another firm may hardly waste a drop. Secondly, with machines having plain bearings, the oil consumption increases extraordinarily in proportion to the average speed, as the bearings are too small for efficiency, and get overheated, unless you keep them drenched with cold oil. But this does not apply to ball and roller bearings, which would run well in a dry state, and are lubricated partly for waterproofing purposes. In the case of an engine fitted with ball or roller bearings, the oil supply is conditioned very largely by the needs of the piston. This brings us to a third variable factor. Some cylinders are excellently designed from a cooling standpoint, whilst others are rotten; cylinder cooling (or its absence) affects piston cooling in turn. One engine has a light, badly-cooled piston, which distorts unless it works in a bath of oil. Another has a piston which does not distort at all. The owner of the flexible piston habitually over oils, just because he knows that plenty of oil makes a good compression seal and prevents konks: the man who has a stiff piston can keep his compression and avoid pre-ignition without sloshing pints of oil through his engine in each hundred miles.

A Case in Point.

IN a certain big trial one or two riders achieved miracles with small engines pulling loads which seemed ridiculous. In one or two cases the riders injected several four-ounce pumpfuls of oil on test hills, to cool their pistons and big-ends, draining the hot oil out at the summit. A novice might learn to use similar tactics—indeed, many do—but would probably omit to drain out the surplus oil at the top of the hill. Heavy carbon crusts then form: carbon interferes with the radiation of heat, and over-oiling is necessitated in the interests of the piston and the big-end bearings.

The Kind of Engine Required.

I HAVE indicated that motor cycle lubrication strikes me as being a sea of chaos. Here is an outline of an engine which should prove economical. Its cylinder should be designed to eliminate distortion—*i.e.*, follow aero lines, into which I dare not enter closely. Its piston will be of aluminium alloy, cooling rapidly, and absorbing most of its own heat expansion by means of a slotted skirt or Ricardo type gaps between the two pressure panels. The main bearings might be of the ball type. The big-end bearings could follow the A.B.C. patent, the big-ends threading over the crank pins, after which rollers are inserted, and retained by half collars bolted into place. The oil reserve would be carried in a sump, and would cool down after circulation through the engine. Such a design includes every factor requisite to oil economy, and first-class workmanship will prevent external leakage at crank case joints and tappet guides. Except for the last item, none of the factors are present in the average motor cycle engine: and therefore it is only natural that in ordinary hands a motor cycle's oil consumption is astonishingly high. My own A.B.C. engine does not embody by any means all of the above points, seeing that it is now four years out of date: but it cannot be made to konk, and it can be run forty miles without the addition of a drop of oil.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

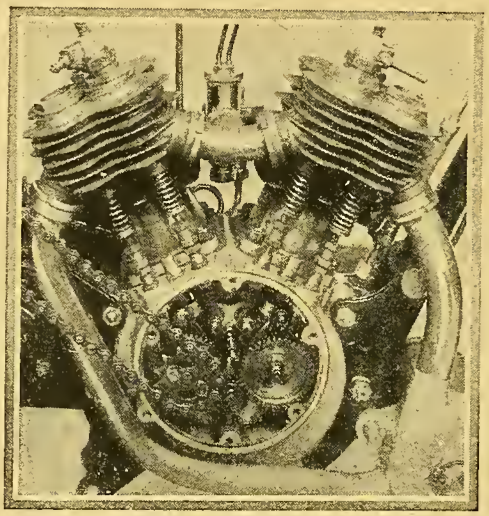
ILIFFE & SONS LTD.

The Case for the Long Stroke

Some Practical Comments on an Interesting Topic by an Experienced Long Stroke Enthusiast.

A COMPARISON of the two engines, long and short stroke singles, shows little structural difference externally, if examples by leading exponents are chosen. Internally the principal difference is, of course, the long stroke engine's narrow cylinder bore and light reciprocating parts. The short stroke theorists inform us that the reciprocating parts of their pet engine can be made almost as light as the corresponding parts of the long stroke engine of similar capacity. In practice, I have never found anything approaching this state of affairs.

TYPES OF MODERN LONG-STROKE ENGINES.



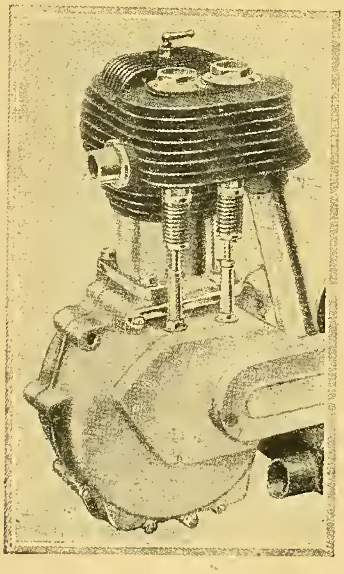
James 3½ h.p., 64 × 77 mm.

Now let us consider the various attributes that we consider desirable in our machines. First, I should place—

Easy Starting.—Personally, I always feel that the longer "induction effort" of the long stroke engine results in a very easy start.

In practice, I have always found this engine the easiest to start next to the horizontal twin. "Gumming up" in cold weather—that bugbear of the average single—I have yet to experience in a long stroke engine. Whether this is wholly due to good design or to the difference in areas of cylinder contact of the two pistons and rings, or a combination of both, I am not certain; anyway, I have never yet required to inject petrol to free any of my long stroke engines winter or summer, even after my machine has stood all night in the keenest frost.

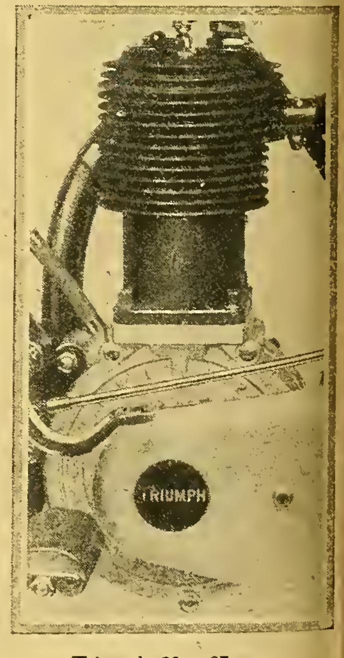
My personal experience of the average "square" engine in this respect has been that injections of petrol for piston firing purposes are generally necessary after a cold night's stand, even without the excuse of a low temperature.



Norton "Big 4," 82 × 120 mm.

Cool Running.—Here again, in practice the long stroke engine scores decisively, and will continue to do so until the theoretical day dawns when our cylinders and pistons are made of non-heat-conducting material. The longer piston travel and relatively slower revolution rate all tend to a better heat dissipation. As a natural corollary to this feature one would expect the power maintenance of the long stroke engine under load on the road to be superior to the short stroke engine of similar capacity. In practice, I have yet to find the short stroke single that will come anywhere near the long stroke engine of similar capacity in cool running and power maintenance under conditions of severe road work. Therefore, for sustained effort, I plump for the long stroke every time. Its average running temperature is lower than that of the equal capacity of square engine, therefore it does not spoil its cylinder lubricating oil to anything like the same extent as does the short stroke. As a result, carbonisation is appreciably reduced. The evidence on this point produced some time ago in our Correspondence pages is most certainly pretty conclusive.

Economy of Fuel and Oil.—Our next most desirable attribute arises directly from the previous heading, I think. A comparison of the two engines is interesting. The square engine over any average run is running at a higher rate of revolutions, and it is running at a higher temperature. By comparison with the relatively slowly turning and cooler running long stroke engine the square engine has a poor



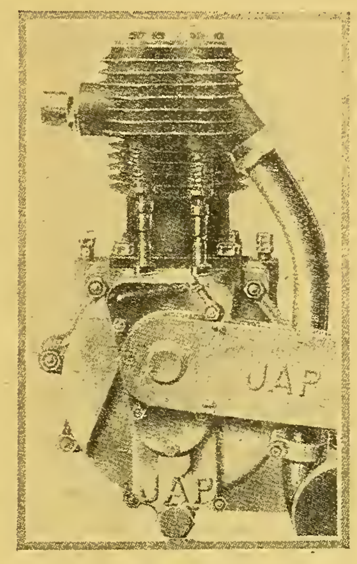
Triumph, 85 × 97 mm.

he Case for the Long Stroke.—

hance of winning the economy stakes for fuel and il consumption.

On benzole the economical running of the long troke engine is simply wonderful, as this engine is ble to utilise to the full the slower rate of flame proagation of this fuel. The driving ffort of a long stroke engine on good enzole must be nearly akin to the lastic push of a steam engine.

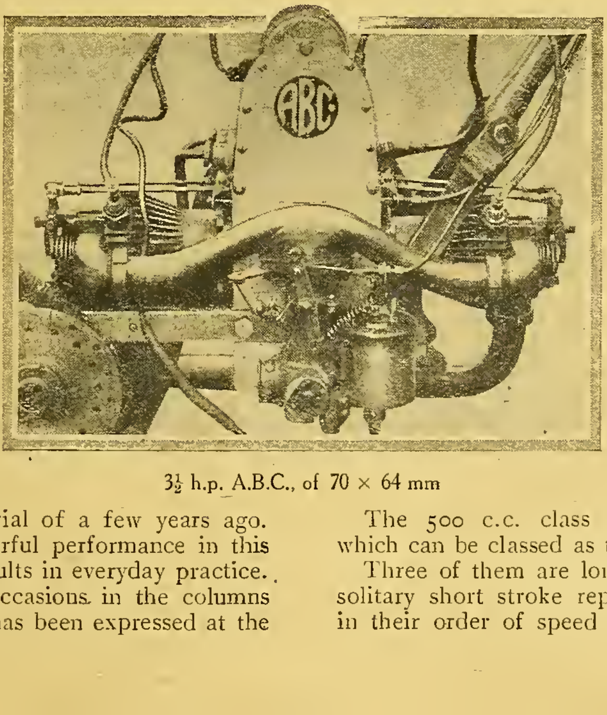
TYPES OF MODERN SHORT-STROKE ENGINES



4 h.p. J.A.P., 85½ × 85 mm

Speed and Power.—I think the short *ésumé* of long stroke engine performnces that I intend to present will ubstantiate my claim that, in this espect at least, nobody can doubt the nique position the long stroke engine ccupies in the motor cycling and car vorld. As an amateur in engineering natters, I have always thought that the ngine which utilised the expansile ush of the burning mixture to the ullest possible extent would be the ngine for power development, without vhich there can be no speed. In ractice it appears to work out so in n unmistakable manner.

Engine Wear.—This question arises rom the subject of bearing pressure, nd the theorists of both sides have old us all about it. Personally I will ack my long stroke engine bearings to e in better condition at 10,000 miles han the bearings of any "square" ingle that has done the same amount of work. At ,500 miles the bearings of a 1915 guaranteed speed nodel long stroke engine of mine were absolutely levoid of shake: so markedly so that the engineer vho took over the machine would not credit its milege—a mileage of genuine hard work, including 350 niles of single-geared sidecar work. In my opinion, he smaller bearing load the slower, cooler running and in consequence better ubrication efficiency), and he better utilisation of the aseous expansion all tend o make the long stroke ngine outlast its short troke brother.



3½ h.p. A.B.C., of 70 × 64 mm

Now let us turn to reults and see how the two ypes of engine have perormed in public.

Here we find that, in roportion to the number f the two types on the oad, the short stroke nakes a very poor showing.

In petrol economy we ave the phenomenal record f 320 miles per gallon by ne 64 × 77 mm. twin James 1 a Sutton Coldfield Club trial of a few years ago. Giving all credit for a wonderful performance in this ase, we do not find these results in everyday practice. Sad to relate! On several occasions in the columns f *The Motor Cycle* surprise has been expressed at the wonderful economy of the 3 h.p. Enfield twin, and, if my memory serves me correctly, "Ixion"—to drag in that unfortunate gentleman once again—on one occasion marvelled at the consumption of this particular engine being so markedly better than the figure for his "square" twin engine of considerably lower capacity.

This particular Enfield engine is a good example of a small twin engine of moderately long stroke.

In the 3½-4 h.p. class, whilst the "square" engine is content with a consumption of from 70-100 miles per gallon solo riding, the 3½ h.p. long stroke engine consistently gives from 90-150 miles per gallon under similar riding conditions.

Whilst stationed at a well-known Lincolnshire camp during the first six months of the war, my 3½ h.p. Norton T.T. averaged 120-150 miles per gallon consistently in that flat county.

A 4 h.p. engined heavily equipped sidecar outfit of the same make, 82 × 120 mm., averaged a consumption of 73-76 miles per gallon, and on one long run covered 162 miles on two gallons of No. 2 spirit over a stiffish give-and-take route along the south coast. The short stroke engined outfit of similar capacity averages from 60-70 miles per gallon, judging from descriptive letters that have appeared in *The Motor Cycle* columns from time to time.

Speed and Power.

Under the heading of speed and power the long stroke engine almost dominates the record list. Twenty-one world's class records stand to the credit of the pioneer long stroke Norton.

Amongst the smaller engines we have had the famous long stroke Levis two-stroke, of under 200 c.c. I believe that attained the wonderful speed of fifty miles per hour—a record speed for any two-stroke engine up to 350 c.c. capacity. In this class, also, the little O.K. Junior, with its long stroke engine, has made its mark.

In the 350 c.c. class the "square" engine, a special one, holds the speed records. To counterbalance that we have the long stroke engined 2¾ h.p. A.J.S.'s clean scoop in the 1914 Junior T.T.—an excellent performance.

The 500 c.c. class sees virtually four machines which can be classed as the world's fastest 3½ h.p.'s.

Three of them are long stroke engines, leaving one solitary short stroke representative. I refer to them in their order of speed as it stands at present *(pace*

The Case for the Long Stroke.—

Mr. Bradshaw)—Norton, A.B.C., Motosacoche, and Triumph. The Norton, as is well-known, is a leading long stroke motor cycle engine. The A.B.C., the solitary short stroke representative, is a redoubtable opponent, and will require watching.

The 3½ h.p. Motosacoche which broke the Norton's record in Switzerland is a long stroke engine, I believe, though I am speaking without my book. Will Mr. O. de Lissa confirm?

Messrs. the Triumph Co., after an historical adherence to the approximately square engine, recently decided that there must be something in the long stroke idea. In the hands of the redoubtable Stanley the new long stroke Triumph promptly clocks 76 m.p.h.—a speed no Triumph had ever attained before.

The Sunbeam Co., formerly square engine adherents, produce a long stroke 4 h.p. single at a 1915 open hill-climb. It promptly annexes the sidecar class at its first hill-climb, and astonishes everyone by its excellent performance.

The 5-6 h.p. Kerry-Abingdon (the performance of which at the power tests described in *The Motor Cycle*, of November 25th, 1915, was so good), the 5-6 h.p. Rudge single, the famous M.A.G. 7 h.p. twin, and the later 7-9 h.p. Indians are all examples of long stroke engine practice and have made their name, as powerful and efficient units.

In the cycle car world we have the big Blumfield twin and the M.A.G. twin more than upholding the reputation of the long stroke engine. The performance of the M.A.G. power unit, in both its air and water-cooled form, on vehicles like the Morgan has been really excellent—in fact, the air-cooled M.A.G. twin can surpass several of its water-cooled square *confrères* in continuous smooth power development.

In the light car world the long stroke engine has given us the ultra-efficient modern light car with its "lively" power unit. Amongst big cars the short stroke engine is in the minority—a condition of things that is not wholly due, as some would have us believe, to taxation anomalies.

ALEX. LINDSAY, M.B.

SOUTH AUSTRALIA M.C.C.

A Meeting at Sellick's Beach.

THE M.C.C. of South Australia still holds competitions in spite of the fact that a large number of its members are at the Front, but with those who have not gone, and now a fair sprinkling of returned men, the Club is again in a flourishing condition considering the times and circumstances. A two days' speed trial was held on the 28th (Foundation Day) and 29th of December last at Sellick's Beach. This is a very firm beach about three miles long, with plenty of width at middle tides, the only inconvenience being its distance from Adelaide (forty-three miles). Weather conditions were so delightful that most of the motorists camped on the beach all night of the 28th, but on the afternoon of the 29th rain began to fall, which caused the postponement of the mile record event for that day.

(Top) Start of one of the semi-finals in the M.C.C of S.A. one mile handicap

(Bottom) A group of competitors. V. K. Torodi (with shirt sleeves turned up) is the chief of the Indian camp. The competitor on the left, with racing helmet, is E. Ferguson, holder of several South Australian records.

The Class half-mile was followed by the South Australian half-mile record attempts for various classes (electrically timed) as follows:

300 c.c. CLASS (PREVIOUS RECORD 42s.).

E. Warren (Elliott-Villiers)	37⅖s.
N. P. Elliott (Elliott-Villiers)	39⅖s.

CLASS UP TO 600 C.C. (PREVIOUS RECORD 27⅘s.).

E. H. R. Hirthe (3½ h.p. T. J.A.P.)	27⅗s.
R. H. Abbott (3½ h.p. Kent-J.A.P.)	29s.
P. W. Carnell (3½ h.p. Lewis)	29⅗s.
E. Warren (Elliott-M.A.G.)	30⅖s.

CLASS OVER 600 C.C. (PREVIOUS RECORD 19⅗s.).

E. Ferguson (Powerplus Indian)	25⅕s.
E. C. Wagener (8 h.p. J.A.P.)	26s.
N. K. Conrad (8 h.p. J.A.P.)	26s.
H. D. Reed (8 h.p. J.A.P.)	26⅖s.
C. Gartner (7-9 h.p. Excelsior)	37s.

PASSENGER CLASS UP TO 600 C.C. (PREVIOUS RECORD 38s.).

L. S. Eglinton (3½ Kent sc.)	37⅗s.

PASSENGER CLASS OVER 600 C.C. (PREVIOUS RECORD 35s.).

*E. Ferguson (Indian sc.)	30⅖s.
*W. H. Hubbard (8 h.p. J.A.P. sc.)	30⅖s.

EXCELLENCE OF WORKMANSHIP

The more closely B.S.A. Motor Bicycles are scrutinized and tested the more is one impressed by the excellence of B.S.A. workmanship. Every part, from the largest down to the most insignificant detail, testifies to the thoroughness of B.S.A. methods and the highly skilled attention each part receives. For many years now, the public has appreciated the value of B.S.A. workmanship, the constant growth of this popularity being fostered by concentrating on B.S.A. Motor Bicycles the most scientific processes known to modern engineering.

THE BIRMINGHAM SMALL ARMS COMPANY LTD.,
Small Heath, BIRMINGHAM.

The post-war CLYNO and -

Its Power

In the Post-War period that comfortable reserve of power, so essential to your full confidence and pleasure, will be even more appreciated than in the days before the War.

And in the CLYNO you'll have an ideal machine in this direction.

Note its Engine specifications—

Twin-cylinder, 8 h.p., air-cooled, medium compression, detachable heads, valves interchangeable, adjustable tappets. Roller and plain bearings to mainshaft. Four - row caged roller bearings to connecting rods. Automatic sight-feed lubrication, with special system of oil feed to pistons.

As also the policy points we have recently announced—

Mass production of one Model

ensuring a price for both outfit and spare parts which will favourably compare with that of any other mount.

Rotational order of delivery.

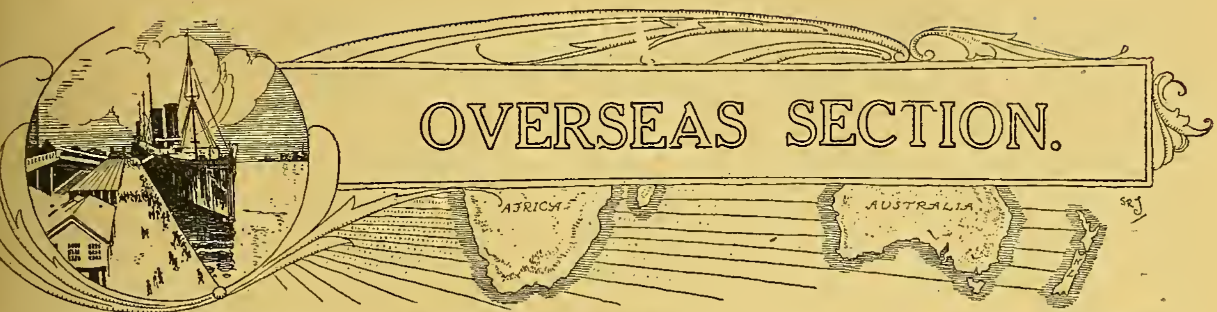
OVERSEAS SECTION.



A Commentary based upon Practical Experience and a Study of Overseas Opinions.

ear Ratios. THE question of gear ratios is one of the many questions of life which is ever vith us. The most desirable system is, naturally, one vhich permits an infinite range between, say, 3 to 1 ind 16 to 1, but such a system unhappily does not xist for a positive system of transmission. The four-peed gear box is as yet the nearest approach to it, ind is fairly satisfactory in that it permits the range of atios to be fairly close together.

Probably most Overseas riders will agree that the resent-day three-speed box falls short of perfection n that the step between the top and the middle gear s too great. When the conditions are such that contant changing is necessary, this big step up and down s a considerable handicap. There are occasions when he high gear is just a hade too high and the niddle gear a good deal oo low, with the result hat one is compelled to un for miles with the ngine turning over a ood deal faster than it eally need, with the esulting burning of alves and unwarranted onsumption of petrol nd oil.

For Overseas use, hen, it is particularly esirable that the two op gears be fairly near ogether—say 5 and 7 to , and so long as overoading were avoided, he necessity for a ratio ower than the 7 to 1 vould seldom be felt, hough a third emerency gear of, say, 14 or 5 to 1 would, of ourse, be necessary. Ve are inclined to think hat a three-speed box ermitting this range vould be more cordially accepted than one giving the resent popular ratios of, approximately, 5, 9.5, and 2 to 1. Many critics attack these typical ratios for se at home, and most of their criticisms apply with ven greater force when the machine is used under olonial conditions.

One of the motor cycles purchased by the American Poets' Ambulance Society, and used in connection with Red Cross work in Italy.

The Four-speed Box. EXPERIENCE has shown, however, that as regards its internal construction a four-speed box need be no more susceptible to breakage and very little (if any) heavier than the present design of three-speed. We should then be permitted the convenient ratios of 5, 7, 9, and an emergency gear decided by the c.c. of the engine.

It would seem that the stumbling-block, so far as Overseas use is concerned, is not so much in the gear box itself as in the striking and operating mechanism. The gate is satisfactory in that it affords a good positive stop for each gear, but it falls short of perfection owing to the fact that, should one of the rods become damaged, the gate no longer registers with the movement of the dogs or pinions, and the more gears we have to deal with the greater is the demand for perfect accuracy of adjustment—a feat somewhat difficult, and at any rate irksome, for the ordinary amateur. We have, indeed, known the operating mechanism to be so slightly damaged that it has passed unnoticed and unheeded, and the gear utilised for weeks with the pinions or dogs only partially engaging. Ultimately the fact that something is wrong is brought home to the rider by the refusal of the gears to remain in engagement, and on taking the gear box adrift it is found that the working parts are so unevenly and badly worn that extensive renewals are necessary.

All this, then, points to the desirability of the gate being contained inside the gear box, so that, whatever may happen to the levers, the various positions remain permanently set, instead of the adjustment having to be conveyed through various rods and bell crank levers, open and susceptible to damage. This system, desirable in the case of the three-speed

Overseas Section.—

box, is even more so in the case of the four, and in car practice it is customary not merely to depend upon the gate, for the selector rods are similarly notched to register with the gate, thus eliminating the likelihood of inaccuracy.

With the enclosed gate the operating mechanism can be badly damaged, but so long as it will work at all the gears can be used without danger of damaging the box internally.

The change-speed lever should possess sufficient range of movement and be of proper workmanlike dimensions—one of the most popular gear boxes of to-day being excellent in this respect, and in the simplicity of its single rod operating mechanism. Silence is a matter dependent as much upon design as upon workmanship, in that, given a wrong design, the finest of workmanship cannot bring about its realisation. This is a point which might profitably be given further consideration, but which, in the design of four-speed boxes particularly, seems often to be eclipsed by other and perhaps more necessary features. Gear boxes, like everything else on a motor cycle, are far from perfection, but are not by any means hopeless.

A Selection of Letters from Readers scattered all over the World.

South African Appreciation of the Zenith.

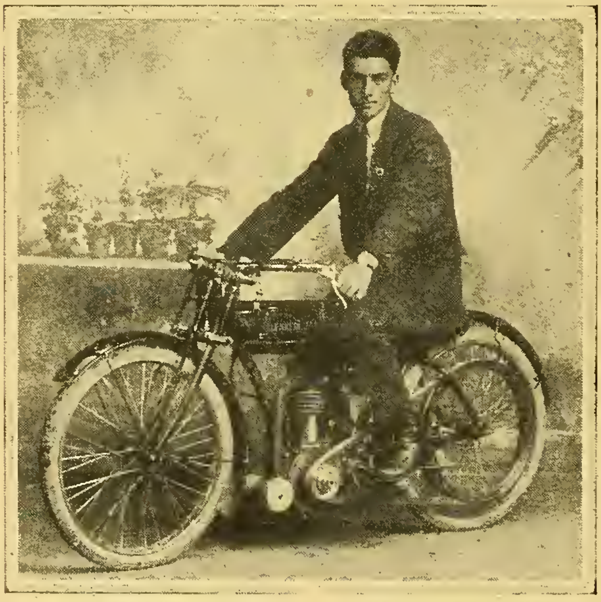
Mr. M. W. Lambon writes from Durban as follows: "On reading through the issue of October 25th, 1917, I came across a letter from Norman Wilson, entitled 'American Trade in Australia,' page 394, and should like to mention that exactly the same conditions prevail in this country.

"The old country does not, or will not, recognise the immense market there is in the colonies for the right type of machine. His ideal machine for Australia complies exactly with what is wanted here, with the exception of where he says he wants plenty of clearance between wheel and tyre, which, in my opinion, would be rather dangerous.

"Following through the numbers of the last three months, I am sure that if Messrs. Zenith Motors ship their 8 h.p. spring frame model over here, when conditions permit, they will hold their own against all comers, in spite of the machine being belt driven. In my humble opinion they have adopted the most sensible spring frame design obtainable."

The J.A.P. Engine in New Zealand.

Mr. George Toms, writing from Blenheim, New Zealand, says: "I am sending you a photograph of myself and my New Zealand-built racer, called the Blenheim-Jap. I am eighteen years old, and came to New Zealand two years before the war started. When I was in England I frequented Brooklands regularly, and was much interested in racing. Mostly I use my machine for knocking about town. It starts as easily as the Douglas. Recently I took it on the beach here—the sands are ideal for speed work—and did one or two sprints, attaining a speed of 60 m.p.h. The petrol consumption is 80 m.p.g. It is the only machine of its kind in New Zealand."



A New Zealand reader, George Toms, on a Blenheim-Jap motor cycle, a machine built up on the island.

Candid Criticism.

"An Australian" sends us the following sensible suggestions: "As a reader from Overseas and an admirer of British motor cycles, I would be pleased if you would let me have five minutes of your valuable time. I am trying my hand at criticism, which, while candid, I hope will be accepted in the best of spirit.

"*Engine* usually too small; out here (New South Wales) a large majority of riders attach a sidecar and want to go anywhere without changing gear too often. The smaller engines must be cleaned regularly, as they have not enough reserve to fall back on.

"*Carburetters.*—Is there any reason why heavier Bowden wire should not be fitted? [A pertinent question.—Ed.]

"*Gear.*—Countershaft, of course, but why hanging by four studs? The Triumph Cycle Co. criticise this method in their own words—see 1915 list, page 28: 'On many machines the tank is fastened to the top tube of the frame by means of clips, etc. For some time we have considered this method obsolete. The Triumph tank is *supported* on the lower horizontal tube, etc., etc.' If suspension were not good practice for the tank, is there any reason why it should be desirable in the case of the countershaft gear? My opinion is that the gear should be supported both top and bottom.

"*Clutch.*—In British clutches bearing surfaces are too small, there being no reserve when a little wear takes place. The American Eclipse clutch, as fitted to big Excelsiors and Reading standards, is a good clutch. The clutches in hub gears went from thick clutch plates to thin; are we going through the same evolution with the countershaft gear?

"*Transmission.*—Chain with shock absorber.

"*Wheels.*—Hubs must be wide; Rudge are a good width, although I would like them a little wider. The Rudge also have strong axles (½in. front), but they should be the knock-through type. Wheels with wide hubs do not need truing nearly as often as those with narrow ones. If Triumph made a wider front hub and fork buttress it would enable them to make a stronger spring. Wheels to be 28×3in.

"*Frame.*—In my opinion, there is only one frame on the road, *i.e.*, one that will stand up under any and every condition, viz., Rudge. This frame is a model for other manufacturers to follow. I have never seen a broken Rudge frame, although I have seen frames bent almost concertina fashion.

"*Forks.*—For simplicity Triumph, but springs break too frequently. All forks should have ball bearings like Triumph. The A.B.C. forks, according to their illustration, look all right, but the bearing parts appear too small. British forks are not wide enough.

"*Handle-bars.*—I like the idea of the A.B.C. fastening but a Rudge or Triumph shape.

"*Mudguards.*—British makers might take a lesson from the best American practice in regard to strength of mudguards. Note the strength of Reading standard mudguards. Mudguards should be as wide as possible.

"*Saddle.*—British saddles are best.

"*Oil Pump.*—Both mechanical and hand pump.

"*Silencer.*—Of the largest possible dimensions; should be made of aluminium, or similar metal, with easily detachable side or end plates.

"*Head Bearings.*—Large, take ¼in. ball bearings.

"I hope you will consider the above as a constructive criticism."

LUBRICATION-FEED SYSTEMS.

A Pump Feed System incorporating a Sump.

THE interesting article by "Chinook" on the subject of lubrication in *The Motor Cycle* of February 21st raises a number of interesting ints. In considering the matter one inevitably mes to the conclusion that manufacturers have the eatest reluctance to depart from any but the most nple forms of lubrication.

There is not the slightest doubt that a maker put on one side all considera- ns of increased weight, extra compli- ion, and considerably increased cost, could turn out a system of oil feed ich would be practically perfect. By s I do not mean that the ultimate rication of the bearing parts would perfect, because this introduces other matter, viz., the adaptability the interior of a petrol engine to per- t lubrication. I am merely taking account the delivering and retain- of lubricating oil in the crank case the requisite quantity, at a minimum nperature, and in the best condition carrying out its functions as a lubri- nt. The internal application of the ricant is a separate consideration gether.

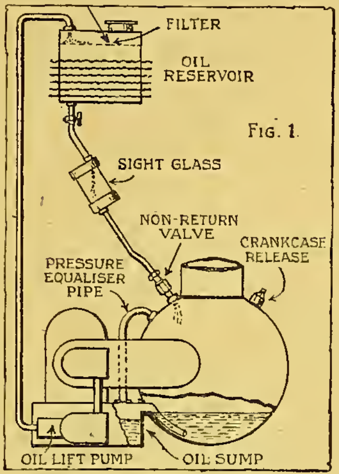


Diagram of a system of oil feed suggested by "Engro."

n feeding oil to the crank case there two evils to be guarded against—(1) giving too le oil, (2) giving too much. It is an impossibility to e the exact amount of feed required. As a com- mise, however, one can arrange to give an over ply and allow the surplus to be drained away. It or this reason that it would appear better to have sump separate from, and not integral with, the nk case. The latter system merely provides for cooling of the lubricant, and does not adequately rd against under or over oiling.

A Suggested System.

An ideal system of oil feed ht be such a one as shown in gram herewith. The system sists of a reservoir contain- n a large filter fitted with ed flanges; a sight-feed glass crank case feed; an overflow n crank case to a sump; a itively-driven oil lift pump for rning oil to reservoir.

he overflow would be fixed ards the front of the machine, that when ascending a dient there would be a slight ease in the quantity of oil in crank case, whilst in descending a gradient there ld be a greater overflow and consequently less in the crank case.

he rate of feed could be as desired, for the sump lift pump would deal with any surplus. In this maximum circulation would give also maximum ling of oil.

Some Criticisms.

What are the practical man's objections to such a system as described? Perhaps they may be summed up as follow: Such a system introduces complication, it upsets the layout of a stereotyped machine, and it adds the cost of some pounds to machines already rising alarmingly in price.

No risks would have to be taken in the design of the lift pump, consequently it would have to be of substantial size—as things go—and it would have to be of the slow speed type necessitating some form of worm gearing.

The size of the sump would naturally have to be almost equal to that of the supply reservoir, to provide for the man who forgets to turn off taps. The position of the pump would be a great bugbear, interfering with silencer and magneto positions.

Ultimately the manufacturer—audibly heaving a sigh of relief—is quite ready to fit a hand pump or any system which approaches it in simplicity, and to trust to the otherwise good qualities of his machine to effect sales.

An alternative to the arrangement shown in diagram is perhaps worthy of mention. Instead of the mechanically driven pump with its complicated drive, etc., a *hand pump* may be substituted for transferring oil from the sump to the overhead reservoir. This, probably, would give as good results in practice as the mechanical variety, and would certainly tend to simplify matters somewhat.

An Alternative System: Circulation of Oil by Utilising Variation in Crank Case Pressure.

In this system, as in the ordinary crank case suction feed, the oil is drawn into the crank case by the upward displacement of the piston. It is quite possible to use the downward movement of the piston for expelling oil from the base of the crank case. All that is required is that there should be sufficient air in the crank case for the pressure to exceed atmospheric by a small amount when the piston is at the bottom of its stroke. By an arrangement as shown in the sketch, however, it is quite possible to vary the pressure in the crank case and so provide the required pressure, and when necessary to reduce or agument this pressure. A two-way—or really three-way—valve is shown. In one position air can be admitted into the crank case through a non-return valve. This has two effects—(1) to increase pressure in crank case so that oil is more readily expelled through discharge, and (2) to reduce the incoming quantity of oil.

Apr.	1st	8.0 ,,
,,	3rd	8.3 ,,

Summer Time.

Although it will have much of the sour grapes flavour—or lack of flavour—about it, for the motor cyclist, the extra hour came as a boon and a blessing to men on the 24th inst.

The Industrial Reconstruction Council.

The Industrial Reconstruction Council is holding the second of important provincial meetings at the Assembly Hall, Edinburgh, on Wednesday, April 3rd, at 8 p.m.

Motor Cycle as Prize.

The Ixion motor cycle given by the North Wales Motor Exchange, Wrexham, in aid of the 17th Batt. R.W. Fusiliers, has been won by Mr. J. Wilson, the winning number being 11,705.

The Dunlop Rubber Co., Ltd.

The directors of the Dunlop Rubber Co., Ltd., announce the payment on April 8th of an interim dividend of 1s. 9d. per share on the ordinary shares for the half year ended February 28th, being at the rate of 17½% per annum.

Fuel Doping in New Zealand.

Many readers will remember that some time ago there was a craze among a certain type of motor cyclist for using various materials to doctor the contents of the fuel tank, the main result claimed being increased m.p.g.

Now the disease has broken out in New Zealand, and wonderful results are alleged to follow from the adulteration of petrol with a small quantity of a patent liquid.

A Grateful Soldier.

A reader of *The Motor Cycle* who is attached to the Headquarters Workshops of a Siege Park in France has written a letter to the Commandant of the Motor Transport Volunteers in the following terms: "In a recent copy of *The Motor Cycle* I see you are asking for volunteers to drive soldiers on leave between the various London termini. On the various occasions that I have been on leave the M.T.V. transport has been of great assistance. I expect to be home again in a short time, and will gladly give up two nights to help you. . . . I have had considerable experience out here, also at home, on road and track, so do not mind what vehicle you put me on. Also I know London very well. Your service is of great help to Tommy in his journey across Town. More power to your wheels!" The writer is Donald S. Parsons, well known to many of our readers as a member of the Essex Motor Club and of the Motor Cycling Club.

When daffodils begin to peer,
With heigh! the doxey over the dale;
Why, then comes in the sweet o' the year;
For the red blood reigns in the winter's pale
The Winter's Tale

Motor Cycles and Morals.

We have always held that motor cycle riding as a pastime is good for both mind and body, consequently we are extremely gratified to read a letter from an American lady to the F.A.M. secretary concerning her son, who is in the U.S. Army. "His lieutenant," she writes, "told us that our boy goes straight, leads a clean life . . . We gave him a good motor cycle and kept him out in the open, encouraging him to ride in the holidays. It kept him from hanging around town and away from bad company. If we had the means we would furnish every 'wild boy' with a motor cycle, and send him out to ride every time he was idle."

Special Features.

SKIDS AND SKIDDING.
LUBRICATION FEED SYSTEMS

Gear Box Troubles.

The chief point of weakness in
countershaft gear box machines used
the various ambulances of the British
Allied armies has proved to be the
boxes. It is to be observed, howe
that the makers of military machi
especially those designed for sidecar
have realised this weakness, and
now turning out enormously strengthe
gear boxes.

The Loan of a Motor Cycle for a Lady.

A lady engaged on important
work would be glad if any reader w
be willing to loan her a motor cycle
the execution of her duties. Referen
of course, would be provided, and e
care taken of the machine. If any re
would care to respond to this request,
shall be pleased to put him in commu
tion with the enquirer.

Aeronautical Trade Route.

Rear-Admiral Mark Kerr, a membe
the Air Council, said recently that
of the first air routes the French
going to establish after the war i
Timbuctoo, when the journey will
only take four days, whereas it use
occupy four months. As a comme
undertaking that will result in a
saving. Four months' food alone w
be a considerable item.

The Motor and Sport.

Several writers in a Canadian spo
magazine, *Rod and Gun in Canada*
denouncing the motor for the detrim
effects it is having upon hunting
fishing. "Improved roads and the
mobile," they say, "will bring abou
extermination of our game birds
beasts"—a state of affairs for whic
cannot blame the automobile, sin
merely indicates the fact that the
laws are out of date and need rev

Angling in England.

In this country the motor has ren
accessible to city dwellers many exc
angling and shooting areas which
enjoyed only by a select few, and
is no doubt that after the war many
sportsmen will be clamouring for
fields. All over the country are
found excellent reservoirs, which
prove remunerative to their boroug
stocked with rainbow trout, for it
be borne in mind that each year f
becomes more and more difficu
obtain. Ten years ago very few rese
would have paid for stocking, owi
their inaccessibility, but the moto
changed all this, and it is to be
that those with authority in such m
will see their way to maintainin
sporting facilities of the country.

il from South Africa.

We are informed that an old whisky istillery at Hetherly (Transvaal) is eing converted into a motor spirit pro-ucing plant.

aution.

Motor cyclists should drive with special aution on the main Harrow road be-ween Stonebridge Park and Wembley. We are informed that the police on this tretch of road have been particularly watchful during the past few weeks.

New Ignition.

A speaker at a recent meeting of a Graduates' Section of the Institution of Automobile Engineers explained a new ystem of ignition which may be used in ost-war racing machines. We are not ermitted to give further particulars, xcepting that a spark "right across the ylinder" is possible.

American Motor Cycle Repair Shops.

The same care and economy in the repair of motor cycles is now exercised in the United States as in England. In the early days there was just as much waste in the U.S.A. as over here, but when these repair shops are properly organised they are sound in efficiency and economical in their working, being run on a thoroughly businesslike line, as we can state after the many visits we have made to various M.T. motor cycle repair shops in the London area. Touching the work in America, it is interesting to note that there is no branch of the Service to which motor cycles are not attached, which is more than can be said of any other means of transport.

The Federation of American Motor Cyclists.

The Federation of American Motor Cyclists is in the United States what the Auto Cycle Union is in this country. We learn, certainly with some surprise, that Canadian motor cyclists are anxious to ally themselves to the F.A.M. This seems a curious idea, because, however efficient a body the F.A.M. may be, we should imagine that Canadian motor cyclists were quite capable of organising their own governing body, and so be independent of control by a body belonging to another nation, however good the feelings between the sister countries may be.

Record Attempts at Easter.

Harry Martin, who is now on the aircraft staff of Messrs. H. Collier and Sons, Ltd., will be riding on Herne Hill Track on Good Friday, at the request of the S.C.C.U., at the meeting held for military charities (nominated by the War Office). He will make attempts on the five miles and one mile track records. Harry Martin, who is fifty-two years of age, is well known to our readers as one of our oldest racing motor cyclists.

The meeting begins at 2.45. Tickets and further information may be obtained from J. H. Stapley, the hon. secretary, Southern Counties Cyclists' Union, 169, Ferndale Road, Clapham, London, S.W.

In view of the rareness of motor cycle competitions—none has been held for nearly three years—the events should be interesting.

Local "Fashions."

We have heard of a case where a certain motor cycle remained on the hands of a colonial agent for over twelve months, merely on account of the shape of the handle-bars, which illustrates the necessity for our manufacturers thoroughly to understand local likes and dislikes, as well as the conditions under which their machines will be used.

Death of a Well-known American Motor Cyclist.

We regret to learn that Alan T. Bedell, who was learning flying in America, died recently after suffering from measles followed by pneumonia. He broke the American motor cycle record last March, on which occasion he covered 1,153.5 miles on a Harley-Davidson in twenty-four hours at Ascott Track, Los Angeles, and a few months later broke the coast-to-coast record on a Henderson, covering the 3,296 miles in 7 days 16 hrs. 16 mins. Bedell was held in high esteem by all who knew him as being a thorough sportsman. His death will be a great loss to the American motor cycle world.

Motor Cyclists Wanted.

The County of Middlesex Motor Volunteer Corps, Southern Group, is anxious to enrol motor cyclists. They undertake night transport work in taking troops across London from one terminus to another, and need drivers not only of motor cycles but of cars and lorries, and require the use of these vehicles in their corps.

Uniforms are supplied, and there is no subscription to the corps. On Mondays there are lectures on motor vehicles, and on Thursdays there are drills and map reading. Every man in the corps has to be a motor driver, and tuition is given free. The headquarters of the corps are at 11-12, Silver Street, London, E.C.2, where application should be made, or to Capt. A. Horsfield, manager of the motor department, Messrs. Selfridge, Ltd., Oxford Street, London, W.1., who has done valuable work for the corps.

The Parent Tyre Co., Ltd.

The Parent Tyre Co., Ltd., announce the payment on the 30th inst. of interim dividends on the preference, ordinary, and deferred shares for the half year ended February 28th at the rate of 5%, 8%, and 24% per annum respectively.

Dissatisfied.

When petrol was 1s. 6d. per gallon, many motor cyclists grumbled because they could not take three persons more than sixty miles on a gallon of fuel. Sixpence per person, or ten miles for a penny. Now ——?

A Sulky Sidecar.

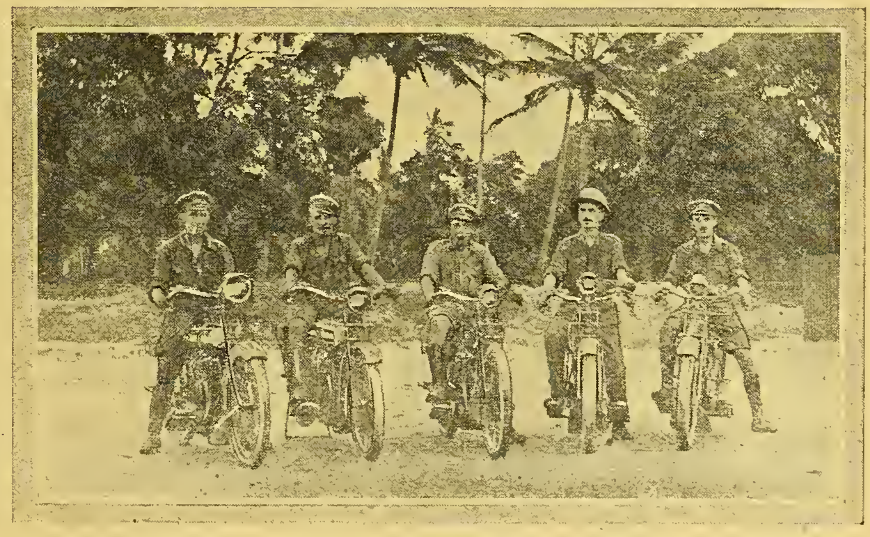
Recently we were much mystified by the reference, by an American correspondent, to an illustration we had published of a "sulky sidecar." On referring to the issue mentioned, however, we found that our Overseas friend had in mind a racing bodyless attachment fitted with footrests and a saddle.

No Smoking Allowed!

They are very strict with riders of motor cycles with visible exhausts in Western Australia. Recently a young man in the trade was demonstrating a new machine to a customer, but had only ridden it a hundred yards or so when a policeman stopped him, and he was promptly haled before the "beak" and fined.

"Some" Engine.

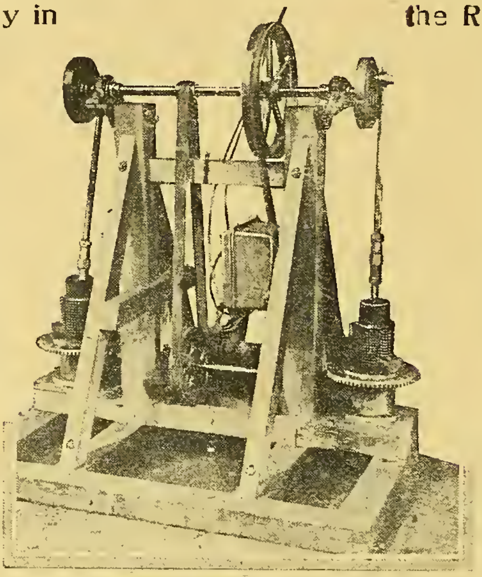
We have before us the specification of a shaft-driven runabout which, before the war, it was intended to market at £80. The engine is described as "*12-16 h.p., two-cylinder, air-cooled, 98×127 mm. bore and stroke, with specially designed piston valves, mechanically operated and interchangeable (no tappets, springs, collars, cotters, etc., to get out of order).*" The capacity of this engine would be nearly 2,000 c.c., and a correspondent asks us for particulars regarding its oil consumption per mile.



A group of D.R.'s in East Africa, taken at Dar-es-Salaam. The names of the men, reading from the left, are: Cpls. Wood, Gooden, W. Day, E. E. Smith, T. E. Brown and G. Wood. They are all mounted on B.S.A. motor cycles.

R.F.C. MOTOR CYCLE REPAIRS.

An Interesting Day in the R.F.C. Repair Shops.



The ingenious cylinder lapping machine, which imparts a reciprocating motion to the pistons and a rotary motion to the cylinders.

THE peculiar conditions under which the Royal Flying Corps works render the corps unique in His Majesty's Army, in that it is the only branch thereof that possesses its own transport system. The M.T. section of the Army Service Corps acts as carrier to all other branches of the army. When the R.F.C. was quite a small force the aeroplanes and their equipment required constant attendance, consequently the transport section was founded quite early in its history, but as the corps grew so the numbers of four-wheeled vehicles and motor cycles increased, and two years ago the M.T. branch reached such dimensions that it required special supervision and reorganisation. This work has been entrusted to, and successfully carried out by, an Acting-Director of R.F.C. Mechanical Transport, a well-known motorist of vast experience whose name has often been mentioned in our pages as President of the Motor Cycling Club.

Some idea of the work involved may be gathered when it is mentioned that the motor cycles alone are covering 500,000 miles per month. The organisation is now just about as good as it can be. The vehicles are all standardised; only two or three makes of cars and lorries are employed, and the motor cycles are now all P. and M.'s. The result is that a comparatively small stock of spares is kept, and the work is considerably simplified. All machines which were not of standard make have been returned to the A.S.C., M.T. Throughout the whole scheme of organisatio economy is the keynote, and waste is practically non-existent. Petrol is used with the utmost caution, and cases of waste are most severely dealt with. Even the dregs from the empty cans are collected drop by drop into a cask and what is collected is used. Depots and garages are inspected at intervals, and reports as to the condition of the vehicle and the way they are used are sent in to headquarters from time to time, and due note, we ma assure our readers, is taken o places where all is not in the most perfect order. In additio to the numerous M.T., R.F.C units scattered throughout the country, the organisation includes a huge garage in the Metropolitan area a distributing centre and training school, and a larg repair depot whither all serious repairs are sent.

The Motor Cycle.

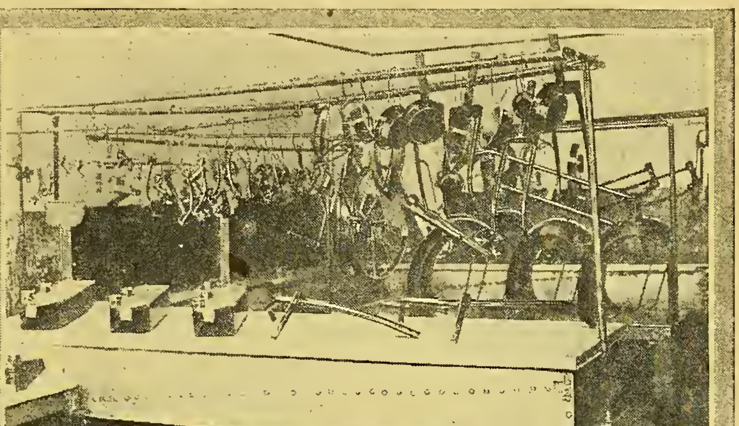
The chief motor cycle repair depot is under th supervision of a well-known motor cyclist, who fo some time was a member of the staff of this journal and served with the Red Cross in 1914, thereby ear ing the Mons medal. The motor cycle shops are we equipped but rather badly lighted. Quite near th entrance there is an interesting tool used for cleanin

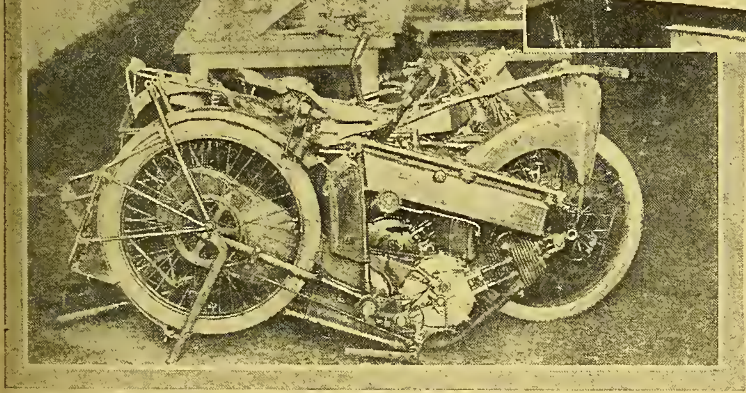
Frame, chain, and tank repairs in the R.F.C. motor cycle repair shop. The Officer in Charge of Motor Cycle Repairs is standing on the right of the picture.

R.F.C. Motor Cycle Repairs.—

parts before repair. It is mounted on a grinder stand, and is driven off the shop shafting. It consists of a "mop" with a phosphor bronze centre, from which radiate equal lengths of discarded aero cable. The parts are first cleared of grease by immersion in baths of caustic soda, and the cleaning is finished by means of this tool. All the ovens and tanks in the enamelling shops were made on the premises by R.F.C. mechanics.

The parts to be enamelled are dipped in a tank, and before being stoved are hung up to drip, all drippings then run back to the tank and thus waste is avoided. The wire wheels used on the cars and tenders are also enamelled in this shop.





(Top) Parts ready for stoving in the enamelling shop.
(Bottom) Motor bicycles sent from Overseas awaiting repair

Near the entrance to the main repair shop there was a stack of badly damaged machines from Overseas, sent in for repair. As we walked the length of the shop we noticed one man fitting new rollers to chains, next to him frame repairs were being carried out, while on an adjoining bench silencers were being dismantled and overhauled. Even saddle repairs are effected by skilled R.F.C. men.

The method of lapping cylinders is also most interesting, not only in itself, but in demonstrating how all parts are used up and practically nothing is scrapped. The machine employed is equipped with old P. and M. flywheels, and imparts the necessary reciprocating motion to the pistons through a pair of cranks and connecting rods. while to ensure perfectly uniform lapping the cylinders are mounted on discarded Crossley crown wheels driven by bevels, by which they are turned. Near by we passed the benches on which engine and gear repairs are carried out, and came across an old friend in another well-known motor cyclist, F. J. Watson, who before the war gained a well-earned reputation as the skilful rider of Swift motor cycles in numerous competitions. Lastly we were taken into a small but compact little testing shop in which there was a test bed on which the P. and M. engines are mounted before undergoing their power test after repair. The engines are made to drive a fan brake, and the r.p.m. are shown by means of a revolution counter. Before bidding adieu to our guide we inspected some substantially built three-point suspended sidecars used by the R.F.C., and spoke in glowing terms of the behaviour of the P. and M. motor bicycles. The officer who showed us round, the O.i/c T.R.S.—Officer in charge of Transport Repairs—was an enthusiastic motor cyclist before the war. He had not long returned from France, where he had met J. D. Drysdale, who used to ride a Hazlewood; R. O. Clark, the F.N. exponent; and E. Kickham, Douglas expert.

THE PREJUDICE AGAINST OVERHEAD VALVES.

A LEADING manufacturer informed me the other day that he would have scrapped side-by-side valves years ago, but for the fact that the average buyer will have nothing to do with o.h.v. I was amazed to learn that such a prejudice exists. It is certainly non-existent in sporting circles, and it is not easy to account for its prevalence amongst the potterers. Presumably they have been frightened by ancient tales of broken valves smashing the piston. The maker in question was rather dubious about his post-war design, considering that the prejudice against o.h.v., of which he spoke quite dogmatically, would still be invincible. It is quite probable that any firms who cling to the side-by-side valve will "crab" the o.h.v. to the best of their ability and repeat or invent tales of its dangers in bygone days. Nevertheless, it should be perfectly safe to plunge on o.h.v. Broken valves must be the sole root of the suspicion which used to exist, and broken valves have been few and far between of late years.

If makers will be conscientious for a year or two, and avoid using cheap and unsuitable steels, this silly prejudice will die a natural death.

ROAD RIDER.

THE AUTO CYCLE UNION.

ANNUAL GENERAL MEETING AND ELECTION OF OFFICERS.

THE annual general meeting of the Auto Cycle Union was held at the Royal Automobile Club on Thursday, March 21st, at 4.30 p.m., Mr. Otto Thomas in the chair. The meeting opened by the Secretary reading the minutes of the last annual general meeting, and a letter from Sir Arthur Stanley, regretting his inability to attend. It was proposed by Mr. E. M. P. Boileau, and duly seconded, that the existing president and vice-presidents of the Union should be re-elected. This was put to the meeting and duly carried, while it was further decided that the three following gentlemen's names should be added to the list of vice-presidents: Colonel F. Lindsay Lloyd, C.M.G., Messrs. E. M. P. Boileau and Otto Thomas. The officers of the Union, therefore, now stand as follows: President, the Hon. Sir Arthur Stanley, K.B.E., C.B., C.V.O., M.P.; vice-presidents, Professor C. V. Boys, F.R.S., Lt.-Col. A. E. Davidson, D.S.O., S. F. Edge, Esq., Brigadier-General Sir H. C. L. Holden, K.C.B., F.R.S., Lt.-Col. D. F. Nicholl, D.S.O., J. R. Nisbet, Esq., Colonel M. O'Gorman, C.B., G. F. Sharp, Esq., A. J. Wilson, Esq., E. M. P. Boileau, Esq., and Otto Thomas, Esq.

Appointment of Chairman.

On being elected vice-president, Mr. E. M. P. Boileau thanked Mr. G. F. Sharp for proposing him, and the meeting for electing him, to this post. He said that he had worked hard for the Union during the last fifteen years, but this work had been a labour of love, and he greatly appreciated the honour which had been conferred upon him.

The Chairman then referred to the annual report, which is a splendid record of the magnificent work of the Union during a very difficult period, and also to the balance sheet. At the conclusion of his remarks, he mentioned that he was vacating the chair in favour of Mr. Nisbet, who had been elected chairman of the A.C.U. Mr. Nisbet then presided at the meeting. He said that when he vacated the post of chairman three years ago he rather felt that he was leaving the Union in the lurch at a very critical time; however, Mr. Otto Thomas had achieved excellent results. He felt that the Union had been well maintained, and that it owed Mr. Thomas a very deep debt of gratitude.

Mr. G. F. Sharp then rose to say how much the A.C.U. had appreciated the work of Mr. Thomas during the last three years, and desired to pass a resolution to the effect that the meeting records the greatest appreciation of the work of Mr. Otto Thomas during the last three years, and asks him to accept the post of vice-president. This was seconded by Mr. H. P. E. Harding, and carried unanimously.

The Retiring Chairman's Reply.

Mr. Otto Thomas in his reply expressed his gratitude for the honour which had been done to him, and said that his one object while he held the post had been to further the work of the Union to the best of his ability, without having regard to his personal interests, though he felt at times that he occupied a somewhat invidious position. He would like to testify to the splendid loyalty and help he had received from Mr. T. W. Loughborough, who was an ideal secretary, and to his colleagues on the Management Committee, Mr. A. W. Torkington (the treasurer), Mr. H. P. E. Harding, and the Rev. E. P. Greenhill.

There being no business other than the submitting of the fifteenth annual report and balance sheet, the chairman declared the meeting closed.

"THE LIGHT CAR."

Cessation of Publication of a Sister Journal of "The Motor Cycle."

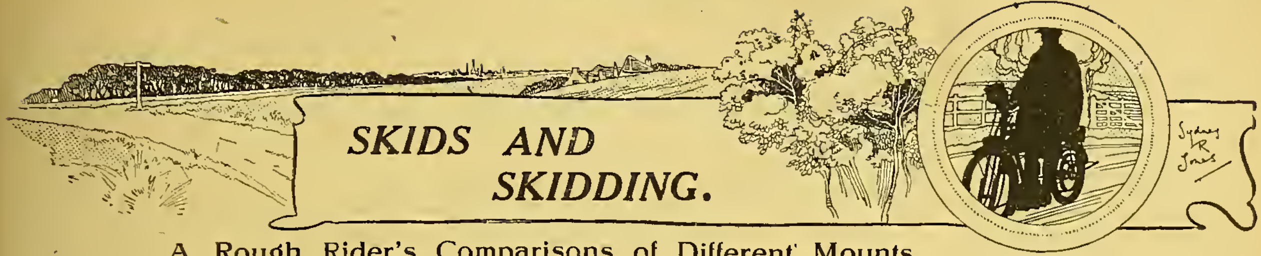
THE issue dated March 27th is to be the last of our sister journal, *The Light Car*. Development of small cars has of late years approximated more and more closely to large car lines, and as a result the light car has justified its patronage by *The Autocar*—which is essentially the journal for all private owners of four-wheeled vehicles.

At the present time, as a result of the really serious paper shortage, the continuance of two journals overlapping in their scope borders on the unpatriotic, and consequently light car users and all interested in these flourishing vehicles will find all that concerns them and their motors fully and competently handled by the oldest motoring journal—*The Autocar*. *The Motor Cycle* will, for the time at any rate, put a rather more liberal interpretation on the term cycle car for the purpose of deciding whether any individual example shall be described in its pages.

Readers who are specially interested in this matter are referred for further information to *The Light Car* of March 20th and *The Autocar* of March 23rd, in which it is fully treated editorially.

Every phase of the motoring movement is now covered completely by three sister journals. *Motor Traction* deals with every type of mechanical business vehicle. *The Autocar* deals with private cars of all kinds, while *The Motor Cycle* covers all vehicles of the cycle type.

Cpl. W. H. Baty, R.E.
He speaks well of the way the Douglases stand up to their arduous work in Mesopotamia.



SKIDS AND SKIDDING.

A Rough Rider's Comparisons of Different Mounts.

DURING the winter the writer had a most excellent practical experience of the art and phenomena of skidding, for he was stationed in the midst of a huge dump of disabled vehicles, which being mostly towed to their resting places by caterpillar tractors, had cut deep furrows into the soft and yielding ground, thus rendering the use of a solo machine anything but a pleasure.

Every variety of adverse weather, from rain through heavy snow to intense and continued frost, was experienced, and it is doubtful which provided the worst conditions, for each phase had its own peculiar terrors and difficulties, and there was every opportunity of making comparisons between the three very dissimilar mounts which were used, viz., a 4 h.p. Douglas, a 7-9 h.p. two-speed spring frame Indian, and a Scott.

The Indian was considerably heavier than either of the other two machines, and on wet grass and mud cut up by the passage and repassage of lorries its extra weight was of some assistance in enabling the rear wheel to bite through to solid ground, and thus gave it the advantage in respect of immunity from wheel slip, despite the more even torque of the other engines.

On really rough going the spring frame was not wholly a success—that is to say, it gave no more actual comfort than the excellent saddle and footboard springing of the Scott—whilst the crossing of deep holes would result in the carrier dealing a smashing blow at the base of the spine, which was decidedly unpleasant, if not actually dangerous.

Illustrating the disadvantage of a heavyweight motor cycle. The rider fell with one leg under the machine, and was unable to release himself unaided.

Carburetters—Automatic or Hand-controlled?

Possibly on account of the extremely cold weather the carburetter was somewhat sensitive to the extra air setting, and for ploughing through heavy, clinging mud at low speeds the pilot jet did not give sufficient power, and there was a noticeable "dead spot" before coming on to the main jet, which often gave rise to violent and occasionally disastrous accelerations if the throttle were carelessly manipulated.

Under normal road conditions this would not have been so noticeable, but it served to emphasise an advantageous detail of the American type of clutch, for in order to counteract the somewhat violent effects of opening on to the main jet too suddenly whilst floundering in soft mud, it was delightfully simple to set the clutch hand lever in such a position that only a definite torque was transmitted, beyond which clutch slip prevented any untoward consequences.

The two-lever carburetters on the English machines gave infinitely greater control simply because the extreme atmospheric variations demanded some adjustments of the air supply. When warm, however, the Douglas would run at all speeds up to 40 m.p.h. without alteration of the air lever, whilst the B. & B. fitted to the Scott required about quarter air up to 25 m.p.h. and almost full air beyond.

A Few Criticisms.

Carburetter settings such as these are practically automatic, and the convenience of having the extra air control at the finger tips *when needed* is surely preferable when compared with a system whose "automaticity" includes the occasional operation of a prehistoric type of shutter on the carburetter itself.

During the spells of dry, frosty weather the 4 h.p. Douglas proved a very excellent mount, with a speed utterly unusable under the circumstances, but it had defects which were very noticeable during rain and snow. The chief of these was the insufficient clearance, and in crossing soft ground it was all too frequently a case of finding the back wheel spinning merrily owing to the footboards and silencer resting on the bosom of Mother Earth. The belt, also, owing to its short centres, was necessarily run abnormally tight, otherwise it slipped abominably.

At temperatures so bitter that flooding the carburetter resulted in covering the float chamber with hoarfrost and ice, the long induction system of the horizontal engine was not conducive to easy starting, but under such conditions engines of any type are a trifle *difficile*.

Skids and falls were much less frequent with the Douglas than with the Indian, because, although the former is by no means a machine with which I

Skids and Skidding.—

readily feel "at one" when riding solo (as a sidecar machine it is quite excellent), yet the low and even distribution of weight tends to keep it upright.

It is very curious how this machine gives a somewhat unjust impression of unrideableness and an alteration of the frame design might obviate this.

The low and short steering head, combined with the rearward position of the saddle, contribute to a sense of insecurity which is heightened by the awkwardly placed clutch pedal at the front and the brake at the rear, spreading the feet in a most unhappy manner for solo riding. This lack of unity between rider and machine is more apparent than real, however, and the stability was quite good, whilst really lurid skids were generally checked by the low footboards, sometimes to their detriment!

The Douglas was practically abandoned as being more suitable for "the 'ard 'igh road" (which was not there), and the Scott used more frequently.

A Twin Two-stroke.

The narrow standard handle-bars of the Scott were immediately scrapped (*pace* the work's experts) and a pair of Douglas semi-T.T.'s substituted, which gave wonderful control, but were just a little far forward for complete comfort.

Riding position, weight distribution and the ease with which a varying amount of slip could be obtained on the low gear rendered it possible on this machine to cross deep mud, inundated grass land, or partly thawed ruts (the worst of all!) at any angle with the certain knowledge that in skidding it would right itself rather than fall.

It is rather curious that, although the ground clearance of the Scott is not by any means too great, the "streamline" arrangement of the undershield and the freedom from rigid projections capable of spragging the machine give it a rather fascinating power of lifting itself through rough going in which more conventional designs would become hopelessly embedded; another interesting feature is the flexible attachment of the footboards, shields, etc., for, although these devices are violently execrated by the rule-of-thumb mechanic, in conditions where smashes are inevitable non-rigidity of certain parts—essentially so designed, of course—may prevent much of the irreparable damage sustained by more orthodox structures.

Summary.

Comparing the three types, the American machine would no doubt be the ideal pioneer type of machine, provided it was always ridden by the ideal pioneer type of man, but for an individual of ordinary size and strength its huge bulk and weight, combined with the high saddle position, render it (on really atrocious surfaces) a somewhat difficult machine to maintain in an upright position.

The Douglas suffered wholly from not being designed for rough country work; its insufficient ground clearance impelling one to be continually seeking the corrugated but comparatively even tracks of the "Holt Caterpillars," whilst its capacity for speed could never be used to full advantage.

It is indeed doubtful if the fast-running flat twin is exactly suited to such conditions as described, for the Scott engine was much more satisfactory, since it was possible to run it so slowly that balancing became difficult, and yet maintain good power.

Of the "rideableness" of the Scott it can only be said that an average, not-too-daring rider may take liberties with this machine not permissible on any other design whatsoever.

These little experiences give a few pointers to features it would be desirable to incorporate in any machine sold for use away from the beaten tracks, viz., good ground clearance, with freedom from rigid projections beneath the machine; frame design permitting a riding position conducive to a sense of unity between man and mount; low centre of gravity; and, lastly, a smooth-running engine capable of giving good power at low speeds.

WHARFEDALE.

CONSERVATIVE RIDERS.

The One Machine Enthusiast—and his Intelligence.

THERE is no accounting for tastes. One still comes across riders who swear by the direct belt-driven single, while everyone else swears *at* it. I know one commercial traveller who weighs at least fifteen stone, and who uses a Baby two-stroke for his long rounds over mountainous country. Regularly he carries huge loads behind, regularly he has to foot-slog up almost interminable mountain ascents, yet, in the face of all obvious fact to the contrary, he emphatically declares that his is the one and only machine suited to his particular requirements.

But for real narrow-minded obstinacy in the choice of machines a certain breed of untravelled Scotsmen I know take some beating. In one little corner of the Lowlands, prior to the war, every machine one saw was a P. and M. According to this little group of riders the P. and M. was the only motor cycle with any workmanship about it, the only machine of decent design, the only mount worthy of a practical engineer and a gentleman. Personally, I appreciated the sterling qualities of the make, but after a few weeks in that district I began to loathe the P. and M.'s. Every few months I made a point of turning up on a 2¾ h.p. works tuned Sunbeam, or A.J.S., or Douglas, taking on the best P. and M.'s of the neighbourhood, and beating them hollow. No matter. The P. and M. remained superlative, and when, on one occasion, my brother and I turned up respectively on a Scott and a four-cylinder F.N., we were simply scorned and jeered at as trouble seekers and experimentalists. I thought we should be *mobbed*, and the amusing part of the whole business was that not one of those dictatorial Scots had ever ridden anything but a P. and M.! One comes across a similar type of Triumph enthusiast. Everyone admits that the Triumph is a good machine and a splendid job, but—ye gods!—it is not the only motor cycle on earth! Changes are pending, and the old conservative brotherhood will do well to widen their outlook and give the new ideas a chance.

KICKING HORSE.

Letters to the Editor

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle" Hertford Street, Coventry, and must be accompanied by the writer's name and address

UTSIDE FLYWHEELS.

Sir,—Concerning the article in February 14th issue of *The lotor Cycle* on outside flywheels by "Chinook," anybody ho has tried starting an engine with internal flywheel and ue with external flywheel on a frosty morning has no doubt hich is the better for a motor cycle engine. I do not now of anything more exhausting than getting to start an iternal flywheel engine that has got well "gummed up."

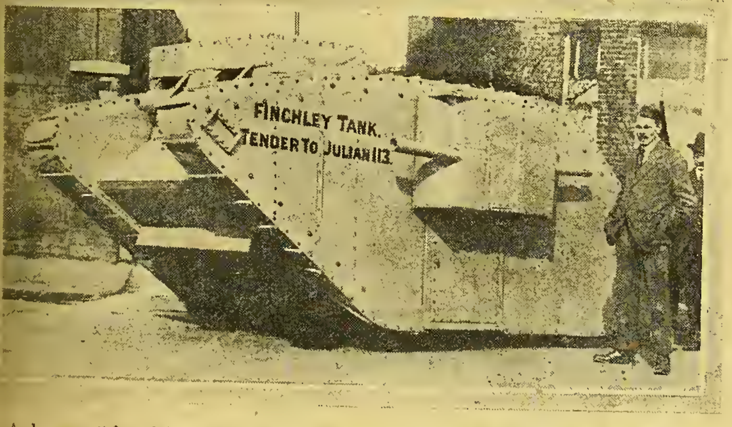
It has occurred to me that an engine—especially a flat win—fitted with *two* external flywheels, one on each end f the crankshaft, would make a beautifully smooth running nit, and do away with a lot of whip in the crankshaft. he opinion of some experts would be interesting.

The majority of flat twins that have been put on the narket up to the present have been short-stroke engines, vith the result that they have not been good top gear nachines. I think that a fairly long stroke would make hem much more dogged and better for sidecar work. My dea runs on something about 65 × 90 mm. Revs. are all ight in their way, but you can get somewhat tired of them n a long journey, particularly on a road like the Great North Road.

K. V. CHIDLEY.

HE "TANK" AT FINCHLEY.

Sir,—I am sending a print of a scale reproduction of a "Female" Tank I made for the Tank week in this district North Finchley). The whole thing is mounted on my -9 h.p. Humberette (water-cooled), and has had a lot of ard use. In all, I have driven about forty miles on low ear, and occasionally there have been three people (including myself) in the car. This is a somewhat hilly district.



A dummy "female" Tank mounted on a 7-9 h.p. water-cooled Humberette, and used during the Tank Week at North Finchley.

The Tank is a scale reproduction of the big Tank, and ccupied about six weeks in building. It consists of main ooden frames and canvas covering, button moulds for rivets, nd cardboard tubes for guns.

I think the way the old 'bus has held up to the severe train is just wonderful, especially as it meant mostly low ear work. The water in the radiator boiled once, partly ue to slight leakage.

G. H. W. RANDELL.

GUDGEON PIN SCREWS.

Sir,—Some little time ago an incident happened to me similar to that which befell G. H. Marshall. I had just started on a trip, and had got about two miles from home, when the grub screw of my piston worked loose, but, instead of working down into the bearings, it fell on to the top of the crank case, and the piston, coming down, struck the screw and embedded it in the aluminium. My machine, which I was riding solo, came to a sudden stop, and, fortunately for me, I was going very slowly, otherwise I should have had rather a nasty spill. In my case, when I had my machine down for overhauling I neglected to replace the pin that helps to support the grub screw, with the above consequences.

It was a lesson to me, and I hope that other readers will be more careful when assembling their machines.

H. CHANEY.

THE BICYCLIST'S EQUILIBRIUM.

Sir,—The following remarks are intended by me to add to the oil which "Mohandis" has poured upon the troubled waters of discussion *re* the forces holding a ridden cycle upright.

I feel complimented by his kindly references to me, and his agreement with my opinion. Particularly am I glad of this, because it was in support of his own contention that I first "chipped in." Then he expresses lucidly my impression of the article by Mr. Jones, recently published in your journal, when he says he "must have studied a different brand of rigid dynamics from that favoured by Mr. Jones." In fact, I had written a question to yourself, Mr. Editor, asking "if a ridden cycle could travel in a straight line." I previously considered it impossible, but the eminent source of the article in question deterred me, for, as I previously hinted, I am not an engineer, but am only "tainted" through environment.

Lastly, regarding your footnote under the article by "Mohandis" to the effect that you are about to publish "conclusions" of this subject, viz., the forces which uphold a ridden cycle.

My opinion about this is: That you may arrive at conclusions without duly taking into consideration the physical strength of the rider, but you will never arrive at the true solution of the problem unless you fully appreciate the element which I am emphasising, and primarily gauge the exact physical strength exerted by the rider when he turns the handle-bar, and deduct therefrom the quota of power lent by gyroscopic action of the wheels and centrifugal force, which, as "Mohandis" points out (and, indeed, italicised on page 253 of March 14th issue of your journal), assists the rider to turn the handle-bar in the direction required. These two forces, being the servants or assistants of the rider, are governed by him. He uses them, and his own strength and weight, to master the tyro's arch-enemy, gravitation.

Therefore, Mr. Editor, no one can define or gauge the respective power of any one or all of these forces, because they are ever-changing, but I look forward with pleasant anticipation to the promised articles.

Please be good enough to bear in mind that I am only expressing my opinion, and have no wish to lay down the law.

TOP HEAVY.

AUTO WHEELS.

Sir,—Permit us to point out that the American Smith Motor Wheel, illustrated and referred to in pages 237 and 243 of your issue of March 7th, is manufactured under licence from us, as we hold the master patents for the Auto-wheel in every part of the world.

We still hold our stocks of Auto-wheel spare parts which were manufactured prior to the war, and are enabled to execute repair work, in spite of the fact that a large number of our men are on active service, through the consideration and help of our present staff, who carry out this section of the work in their spare time.

AUTO-WHEELS, LTD.
W. H. THOMAS, Manager.

LUBRICATION IN INTERNAL COMBUSTION ENGINES.

Sir,—I note that Raymond W. Shimmins in *The Motor Cycle* of March 14th accuses me of making statements as to the relative life of steam and internal combustion engines which are "obviously absurd." One of my statements was that certain types of steam engines have the cylinders cast thick enough to allow for several reborings. This I think you will find correct if you discuss the matter with any locomotive superintendent of a big railway company. The fact that some other engine did not want reboring has nothing to do with the case.

Now with regard to the gas engines. I quoted an engine that I knew was in good condition after seventeen years' work. Raymond W. Shimmins says it was fit for the scrap-heap. *Bon.*

I enclose the name of the owner, and, if you care to, you can verify the facts, and also publish your ideas as to whether he was a man who would care to run an engine fit for the scrap-heap and whether he was a competent man to judge whether it was so.

Perhaps Raymond W. Shimmins read my expression "seventeen years' continuous work" as meaning that it ran night and day for seventeen years without stopping. If so, I may say that I did not mean this, and I do not think many people would read it so.

Let us remember the point under discussion, which is simply whether *every* steam engine is *per se* far more durable than *every* internal combustion engine simply because it is a steam engine; or whether the short life of certain types of petrol motors is due to their being very light and running at a high speed under adverse conditions, etc.

F. STRICKLAND.

[The name of the owner of the engine is well known, and we accept our correspondent's statement.—ED.]

A PLEA FOR LOWER GEARS.

Sir,—I must first thank you for the sustained—indeed the increasing—interest of *The Motor Cycle.* I find therein almost weekly letters or articles which make me wish to take part in discussing them, and which I read again and again to make sure no word or turn of a phrase has failed to reveal its whole meaning.

I hope you are preparing to start a weekly called *The Cycle Car,* for although the subject is dealt with both in *The Motor Cycle* and *The Light Car,* it will obviously require separate attention soon.

The contributions of "Ixion" and "Chinook" especially interest me, and one gathers that these writers have had very great experience of motor cycling. How I envy them when my own few paltry thousands of miles remind me that I had best "lie low and say nuffin"! However, I have a suggestion to make, and, so that it may appear reasonable, must first relate my experience.

I have had a phase of riding in which the highest possible average speed *while running* was attempted during journeys between London and Peterhead. My best effort was 21 m.p.h. on a 1913 three-speed James-Canoelet for the 558 miles, coming south, using neat paraffin at the rate of 90 m.p.g. (These figures were most carefully observed.) Incidentally, the frame has since broken after a smal further mileage at low speeds.

I came to the conclusion that it was not worth whil exceeding 25 m.p.h. on British roads, for the followin reasons: Driving at 30 m.p.h. became a series of accelerations and decelerations, because of the frequency of cros roads and turnings, of twists in the road, of patches o bad surface, of dense traffic, and of high winds. Scener was necessarily almost forgotten, and quick wear of th transmission was evident.

It was obvious at once that lowering the road speed wa no cure without also lowering the gear ratio to avoi excessive pinking. I found 6 to 1 right for a speed o 21 or 22 m.p.h. Hill-climbing and picking up qualities wer excellent, and the engine seemed as happy as I was. could talk comfortably to my wife, look round at th scenery, pass a taxi on the level and a car on a hill. Th road seemed to be smoother, cold weather riding not s chilly, and movement of the throttle was required only t avoid revving the engine above 1,700 per minute, which, i indulged in with my particular machine, generally prevented the next stiff hill from being climbed on top. Moreover, a touch of speed came when a straight, clear, down hill run could be taken in neutral. Blind turns in th road and possible police traps ceased to worry. Th average speed *while running* still worked out at 20 m.p.h. and the petrol consumption actuall close on 100 m.p.g.

The smoother and more beautif secondary roads could be used instea of the often pot-holey main road which resemble railways and inspi one with the desire to get as quickl as possible to the end of the stretc in view. High speed in itself giv me great pleasure, but it has too man disadvantages. I do not say that never longed for a higher gear wit which to tick smoothly along the ea stretches not steep enough down f neutral. But when a 4½ or 5 to 1 t gear was in use I more often wishe for 6 to 1. This proves that t infinitely variable gear is "it."

Now, sir, "Ixion" calls himself "road incinerator," and "Chinook longs for top gears of 3½ and 4 to These gears require rich mixtures, hi speeds, and low compression engines the pink of mechanical condition sidecars are to be used in comfort, a it is then we hear about consumptio as low as 50 m.p.g.

This brings me to my suggestio which is that you should include articl by a contributor of equal experien who finds pleasure in the modern lo geared machines. The fact mention by "Chinook" that makers are n

On certain areas of the Western war zone, less well-known makes of motor cycles are used in the French Army. The photograph depicts a D.R. and his Peugeot in the district of the Vosges.

turning out machines geared lower than 5 to 1 proves that the majority of their present customers wish it. Hence this class—probably the silent majority of motor cyclists—is worth attention.

The makers could cater for both classes by providing a four-speed gear giving direct drive on the two higher ratios, such as I suppose the new 6 h.p. P. and M. has, or could have. W. R. DEUCHAR (SEC.-LT. R.E.).

THE UNITED COUNCIL.

Sir,—I write to express my opinion, as a motor cyclist, on the sentiments expressed in your leader headed "Motor Cyclists and the United Council" in your issue dated 21st February, and I support, as a member of the A.C.U., your suggestion that the A.C.U. should appoint delegates to the United Council. I maintain that motorists have not received the consideration due to them for the many sacrifices they have made in the interests of the country. Consequently I was interested in the meeting convened by Mr. Goodwin on Friday, February 1st, to discuss the position of motorists and the motor industry; and I certainly agree that *united action* is necessary. Personally I am confident in the ability of the A.C.U. officials efficiently to combat any action on the part of the United Council detrimental to motor cyclists. The possible gains are greater than the possible losses. W. WRIGHT.

CARBURETTER ADJUSTMENT.

Sir,—Being rather a Binks enthusiast, the letter in the last number of your paper from Mr. Connell has interested me. As he asks for the experience of others, I give mine.

In November, 1915, I bought a second-hand 2¾ h.p. Douglas—my first Douglas—which I still have. With the carburetter then fitted I found it impossible to get the speed to less than twenty on top, owing to worn valve guides, the back cylinder being the great offender.

In the spring of 1916 I bought a Binks, and when adjusted it gave me ten miles an hour on top gear and any reasonable speed on the main jet. As regards power, the first time I tried the Binks I climbed a local hill at twenty-five on top, which I only once had succeeded in getting up with the old carburetter without changing down.

I have now got 1916 cylinders and pistons, and the machine will do from five to forty-five on top gear. I use 000, 1, and 7 in summer and 00, 2, and 7 in winter. I have taken the cover clean off the bottom air holes, and in summer open the extra air port when using the main jet.

A friend of mine who has a 1917 3½ h.p. James has got over fifty with a Binks, and another friend over sixty on an 8 h.p. Bat-Jap o.h.v. twin with a passenger on the carrier. He also, if I remember rightly, had a No. 7 main jet.

As regards Mr. Connell's complaint of being able only to "smell" the main jet, I fancy Messrs. Binks state that the maximum power is obtained when just opening on to the main jet.

I have come across many users of these carburetters, though, strangely enough, all on twins, and the only complaints I have heard have been that they are sometimes rather hard to start, and that the controls are unwieldy and ugly. In fact, I have altered mine entirely to suit my T.T. bars, and have changed the wires over, making the control standard pattern.

One thing I have noticed in the case of people who use the Binks, and that is that they are inclined to use too large a jet. A No. 7 is usually about right for solo work under normal conditions. Anyway, of all the people I know who have used the Binks carburetter, only one rejected it, and he was a confirmed tap twiddler, who got peevish because it was not necessary to use the air lever with a normal jet setting.

I myself shall continue to use the Binks until the perfect automatic carburetter arrives, for I prefer it to any other I have ever tried. Perhaps Dr. Lindsay can throw some light on the elusive difficulty of your correspondent, as he has had plenty of experience of the Binks on the Norton.

(REV.) JOHN CONOLLY.

Sir,—In reply to H. A. Connell, I had the same trouble with a Binks carburetter for the best part of last year, and traced it to the fuels which I was using. Your correspondent can rest assured it is want of good petrol that troubles him. My machine is a 70 × 70 mm. two-stroke, and with good petrol I obtain splendid results with jets 000, 2, and 6. For well over the first half of 1917 I had to run on all kinds of substitutes, and never once could I get on to the main jet, though I tried every main jet I had or could get. Even with what I got as petrol it was the same. Latterly, while running on naphtha, or crawling rather, I thought I would try something else, so put a No. 9 main jet in the second pilot jet position and a No. 2 pilot jet in the main position; the power returned, and so did the running on the main jet. On half petrol and naphtha the jets are 000, 6, and 7; half petrol and paraffin the jets are 000, 6, and 8. No. 6 jet is really a main jet for my machine, but these were the only kind of combinations that enabled me to run on the main jet position, and with anything like power. On one occasion I got a gallon of good petrol into my tank. I think it was a mistake on the part of the dealer who sold it. Anyway, I had to change back to my old combination 000, 2, and 6. It ran splendidly all afternoon, but at 9 p.m. refused to take the main jets once more, so I changed to 000, 6, and 7, and all was well. This proved it was the fuel which was the root of the trouble, and this set me thinking many things, because there was really no economy nor yet smooth running of which to boast.

One cannot expect good results with poor fuel. With jets 000, 2, and 6 I could get a mileage of close on 100 with passenger on carrier when good petrol was obtainable, but when the main jet is in the pilot jet position the mileage shrinks down a third anyway, and the smooth running goes also. I hope my experiences will be of a little assistance to Mr. Connell. SYPHONIC.

Paisley.

MOTOR CYCLE DESIGN.

Sir,—I read with interest the short report you gave in *The Motor Cycle* for February 21st of Mr. Pendrell's paper on the above subject. He calls attention in one place to two very serious defects in design of all, or nearly all, British machines.

(1.) The method of gripping the handle-bar stem by friction of a split collar only. Many serious accidents have occurred through this idiotic design: not good enough even for a pedal cycle. Since no rider requires to revolve his handle-bars, why in the name of commonsense not make a *square* stem to the handle-bar and make it slide in a *square* socket with clip? The same applies to the seat-pillar. As no rider wants to ride with a saddle out of square, the saddle should have a square clip instead of a round one, and the saddle pin should also be square. If this were done the very frequent occurrence of a shifting saddle would be an impossibility.

With regard to the handle-bar gripping, the American machines of best makes are ahead of us, as they braze the two blades of forks on to the handle-bar, so that it is impossible for the wheel to turn without the bars turning also.

(2.) Detachable back wheel spindles. As far as I know, only the makers of the Sunbeam fit a detachable spindle with "gap piece," by removal of which the tube can easily be slipped in or out without disturbing the transmission at all.

The only alternative on other machines is to use a butt-ended tube, and this is an endless nuisance, as I know from experience.

Curiously enough, many makers use a detachable spindle for the front wheel, where it is not so necessary, as the front wheel is so easily removed, but they do not fit such a spindle to the back wheel.

Caged ball bearings (or, better, roller bearings) should be fitted to both wheels and sidecar wheel also, and the back spindle should not be less than ⅞in. diameter and the front wheel ¾in. diameter. The present wire-like spindles are a disgrace to any "engineering" firm, and have caused numberless accidents. The slight extra cost and weight of the necessary steel are not worth considering for an instant when in such vital parts of a machine as the wheel spindles.

Let us hope that after the war our leading manufacturers, at any rate, will use more intelligence in their designs than they do at present. As to British-made magnetos, I have found the C.A.V., at any rate, better than any Bosch. It is reliability itself and gives a very good spark at low speeds, hence, giving a very easy start, even on a long-stroke engine like the Norton or Rudge big singles.

Beech, Alton, Hants. M. HITCHCOCK.

[Is our correspondent unfamiliar with the A.B.C. handle-bar and the detachable wheels fitted to the Clyno, Lea-Francis, A.J.S., and other machines, which enable the rear wheel to be bodily removed in a few seconds without disturbing the transmission?—ED.]

"THE MOMAGU."

A Service Journal of a Battery of the M.M.G.S. in India.

FROM Rawalpindi, India, comes the first copy of the magazine of a battery of the Motor Machine Gun Corps, and a bright little original journal it is. The few photographs shown are entitled "Reminiscences on Tour," and depict the men of the M.M.G.S. at practice, also a mountain pass which is typical of the scenery on the N.W. Frontier. These we have taken the liberty of reproducing.

The little journal is "proprieted" and designed by Sgt. J. R. Slater, and an amusing touch is afforded in the editorial page, where it is stated that the editorial offices are situated at Sergeants' Bunk No. 2, Victoria Barracks, Rawalpindi.

The origin of the title *Momagu* is interesting. Although it has a distinctly Indian sound, it is really very British. The first two letters of the first three words in the nomenclature of the battery were taken, the result being an original and applicable title.

From the remarks of the Editor—who, by the way, is Gnr. J. T. Gough—we cull the following, which may be of interest:

"On landing at Bombay we met with the information that we had four days' railway journey to Rawalpindi. We arrived safely, but before there was time to settle down we were called out for inspection, very shortly afterwards proceeding on a tour of the N.W. Frontier.

"Probably we were of considerable interest to all Army Headquarters, as we were, and still are, the only motor unit of our kind in the country. It is surprising to think that on this particular tour we saw considerably more of the Frontier than has any other white being, with a few exceptions. Those who have enjoyed the same privilege have only been able to do so in the course of about twenty years.

"This battery, of course, is composed entirely of men who enlisted for the purpose of fighting in France, but we were sent to India; and, not knowing what to expect, we were highly pleased to receive this order.

"We have now been in the country for almost two years, and our views have undergone a considerable change. Being accustomed to receiving the best treatment in Blighty, it felt very strange to be stationed in a country where the 'duration man' is not understood. No one realises that practically ever man in Kitchener's Army has sacrifice an excellent civilian position to serv his country. We have heard of a park not a hundred miles from Calcutta where a notice once appeared to th effect that 'Dogs and soldiers are no allowed in here.' It is to the credit o the Territorials and 'duration' men tha they are living down this prejudice.

"To you at home it must be strange t know that prices of various importe stuffs have only recently increased o account of the war, and are still greatl less than the prices prevalent at home."

Scenes taken wit the *n*th Batter Motor Machine Gu Service whilst on th North West Frontie of India. This batter is the only motor un of its kind in India

◆

The Motorists' Protection Association.

ON Thursday, the 14th inst., the first meeting was held of the Motorists' Protection Association.

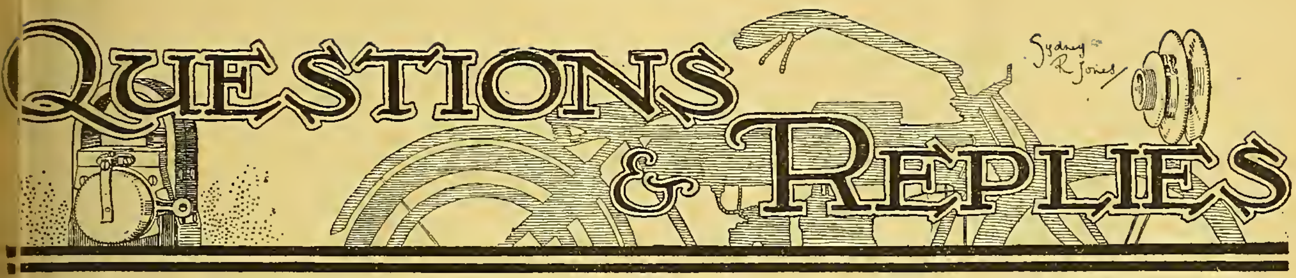
Out of the 550 motorists who had promised their support to the new organisation, only about one-tenth were present at the meeting, but, of course, it is obvious that at the present time, even more than in normal times, only a very small proportion of those willing to help and support the scheme would be in a position to attend the meeting. And, indeed, from one point of view, we think it may be taken as a good sign that so small a percentage of those who had responded were able to be present. If practically every supporter had been at the meeting, the idea would have immediately been set afoot that the body was primarily one of London motorists, and consequently would not have so much the interests of provincial users at heart as these would have every right to expect.

The name of the Association was settled upon as the Motor Users' Protection Association, and the policy or objects of the Association were handed on to a committee for investigation. These objects are:

1. To combat the anti-motor prejudice of a large section of the public press.
2. To resist excessive taxation.
3. To fight the petrol trusts and ot rings or societies which are antagoni to the interests of private motorists.
4. To take prompt action against suppression of private utility motorin
5. To prevent the imposition of reasonable restrictions in future.
6. To urge the Government to uti the revenue derived from motor ta (after the war) for its legitimate pur —that is to say, for road improvem

Any desirous of further informa should apply not to *The Motor Cycle*, to one of the two hon. secretaries, Mes H. E. Sanderson and H. E. Hayes, Su House, Howard Road, South Norwoo

QUESTIONS & REPLIES



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

A Carburetter Query.

(1.) I have a B.B. variable jet carburetter, which has been pretty reliable on a 4 h.p. single-cylinder. I have recently fitted it to a 6-7 h.p. twin. Do you hink it is suitable? (2.) I sometimes nanage to start the engine after a ouple of turns; then, after it stops and attempt to restart it, it may need a lozen turns before it will fire. (3.) Should the petrol stream through the et when it is turned on, or should the uction of the engine draw it?—P.M.D.

) If properly tuned up, the carbu-ter should be quite suitable. (2.) ficult starting may be due to the in-fer petrol that is now being supplied.) The petrol should not stream through t jet when it is turned on, and the ural level should be just below the of the jet, so that the petrol only ws when the engine is drawing in a urge.

Reducing the Compression.

I have a Rex 5-6 h.p. twin, which will not run slowly, as it is fitted with automatic inlet valves. If I put two thin brass washers at the bottom of the cylinders, vould these make the engine run more lowly and give more power? In a win-cylinder engine should the explosions follow one just after the other, r is one piston on the suction stroke when the other is on the firing stroke? f I have the carburetter touching one f the cylinders, or the petrol pipe ouching the cylinders, would this do ny harm as regards making the petrol oo hot, and would it give more miles er gallon, and make the engine more asy to throttle down?—J.F.

, the fitting of brass washers as sug-sted would reduce the compression, and, ough they might make the engine run re slowly, you would undoubtedly get s power. With regard to your second ery, this is answered in "Motor Cycles d How to Manage Them," current ition, page 46, which can be obtained m any bookstall, price 1s. 6d. When e cylinder is firing the other is drawing gas. Yes, if the carburetter is warmed would have the effect suggested. If e petrol in the pipe gets too hot it may use a vapour lock. It is, however, tter to take in the air warm than to at the fuel. We should therefore advise e fitting of a warm air intake on the es often described in *The Motor Cycle*.

Material for a Washer.

I have a small two-stroke of unknown make, in which the exhaust and induction lugs are in one casting. Please tell me the best material to make the joint between lug and cylinder. It will have to stand the heat of the exhaust and yet make an airtight joint for the induction system.—R.L.B.

We should say that the best washer would be one made of copper and asbestos.

Use of Petrol.

I have a motor car, for which I am allowed ten gallons of petrol per month. Should I be allowed to run my motor cycle on a quantity of the petrol, or is it necessary to obtain a separate petrol permit? The motor cycle would be used for just the same purpose as the car.—B.K.

To be quite on the safe side, it would be as well for you to communicate with the Petrol Control Department, and to inform them that you propose, with their consent, to use a certain amount of the motor spirit purchased on your licence for a motor cycle. The Department will have no objection to this course being adopted, but a letter from them stating that you may use the spirit on a motor cycle might be of use in the event of your being stopped and interrogated by an exceptionally conscientious police constable. We assume, of course, that your present licence is of the full-duty variety.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

THE NEED FOR ECONOMY.

Owing to the present drastic restrictions on the import of paper, the most rigid economy is necessary, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week, thus avoiding chance buying, which may lead to wastage owing to copies being left unsold.

Controlling the Fixed Air Supply.

I am in possession of all three of your books—"Hints and Tips," "Tracing Troubles," and "Motor Cycles and How to Manage Them"—from which I have derived a great deal of useful and valuable information. I also receive my copy of *The Motor Cycle* regularly. I have latterly been experiencing some starting difficulty with my 3½ h.p. B.S.A., and on covering the air intake I find I can start up quite easily. My carburetter is a 1912 B. and B., and I believe my trouble is identical with "Road Rider's" as described in paragraph 210 in "Hints and Tips," and I want to know where I can obtain such a device as is referred to for varying the amount of opening of the air intake.—J.W.

We do not know of any such device on the market at the present time. It would be possible, however, to make or adapt one. A second-hand diaphragm pattern photographic stop would do admirably for this purpose.

A Stuck Piston.

Owing to the petrol restrictions I have had to put my machine away, and I omitted to inject any petrol in the cylinders to prevent the pistons from gumming up. I eventually found that I was unable to turn the engine, so I think it is gummed up. Will you please tell me the best and easiest way to get it in working order again? The machine is a new one—1917 5-6 h.p. twin three-speed Ariel, countershaft gear model. How many miles per tankful of petrol should I get out of it? The tank holds 1⅝ gallons, and having a No. 28 jet in, I am able to get about seventy-four miles on this with sidecar.—W.H.W.

The engine is probably gummed up, and your best plan will be to put a little paraffin in the cylinders (not petrol), leave it standing all night, and then attempt to rotate the engine. Having done that, if you have any petrol left, start up the engine and lubricate it generously. This will adequately lubricate the cylinder walls, and the engine should be then efficiently protected from rust for some time to come. Of course, if it is very badly stuck up, the cylinder will have to be removed. Your consumption is certainly inferior to the average. You ought to obtain about ninety-five miles to the tankful.

Crank Case Oil Level.

Whilst reading the article by "Chinook" in *The Motor Cycle*, my interest in lubrication was aroused, and I should be very much interested to know the oil level and exactly how much oil my crank case contains under normal circumstances. My machine (a 4-5 h.p. Zenith) is fitted with semi-automatic lubrication and a hand pump in case of emergency. What I should like to know is whether there is any objection to my drilling and tapping the crank case and fitting a gauge similar to that fitted to a very popular four-cylinder two-speed American car.—E.H.

If you wish to know the approximate quantity of oil your crank case contains, you should lubricate the engine to a normal extent, and after a short run open the drain tap, measure the oil which drains out, and this will give you an approximate idea. The difficulty is that motor cycle oil is rather thick, and consequently you will not drain it all out, as some adheres to the flywheels, the cylinder walls, sides of the crank case, etc. The only good method of ascertaining the oil level would be to fit a glass window in the crank case, as is found in the Indian, F.N., and other motor bicycles. Such a gauge or window could be fitted to the crank case without much difficulty. You would have to fit a brass disc, which would be a proper machined fit against the crank case, thread the interior rim, and screw in a thick glass in a brass frame, the edge of which is threaded, about the size of a small watch dial—that is to say, if you cannot buy a window, and this, we fear, would be rather difficult at the present time.

A Steam Motor Bicycle.

(1.) Are there any disadvantages in using steam for motive power on a motor cycle, using a flash boiler? (2.) I want to use a three-cylinder single-acting engine to develop 6 h.p. at the wheels, geared 4 to 1 from the engine. Can you give me the bore and stroke? (3.) Can I get 200 lb. pressure with a flash boiler using a paraffin blowlamp? Is this suitable for such an engine? (4.) Will you please refer me to any design of a steam-propelled motor cycle in any back number of *The Motor Cycle*? (5.) What type of valves would be suitable; I want to get a speed of about thirty-five to forty miles per hour?—F.S.

(1.) The general difficulties are the provision of a proper boiler and a suitable burner, also the storage of an adequate water supply without increasing the weight unduly. (2.) Assuming that the pressure is 200 lb. per square inch, and that when giving off this horse-power the mean effective cylinder pressure will amount to threequarters of the boiler pressure, three cylinders 2 × 2in. would suffice; 1⅞in. bore by 2¼in. stroke would probably give better proportions, however. It is doubtful whether such a mean effective pressure could be maintained, and, therefore, rather larger cylinders might be advocated. (3.) You ought to be able easily to get 200 lb. pressure. Flash boilers can work up to 600-900 lb. per square inch pressure. (4.) *The Motor Cycle* of November 29th, 1917, contained a description of a steam motor cycle. (5.) For the high temperature, high pressure steam of a flash boiler, poppet valves are the only ones possible.

Hints on Driving.

Before the restrictions in the use of petrol came into force, I was a learner on a 2½ h.p. Jap-engined New Imperial. As I am seventy years of age, I should like to know if I injure the machine by running principally on the low gear? I am now residing in the country, where there is little or no traffic, so have a good opportunity to learn.—W.K.

We should recommend you not to run the machine on the low gear longer than you can help, as this causes excessive wear on the engine and overheating. We should advise you, therefore, to change into top speed as soon as you can. and then, if you wish to run slowly, throttle the engine down. You will soon learn how to do this after a little practice.

Petrol Again.

I noticed in *The Motor Cycle* some time ago that "permits may be granted to soldiers on leave from Active Service." Does that mean that we only require to ask the Superintendent of Police and we get one? Also I have a 1913 Matchless, and intend getting a newer machine. Is it necessary to have a licence to exchange or buy a new one? I have been in France for three years and have lost touch with all these matters.—I.T.

You will have to write to the Petrol Controller, 19, Berkeley Street, placing the full circumstances of the case before him. If you cannot write at least three weeks before you intend to come home on leave you should notify the Controller of your intention to call for the licence on a certain date. It is impossible to buy a new motor cycle from the makers without a Class A certificate, which may be obtained under certain circumstances from the Priority Branch, Ministry of Munitions, Whitehall Place, London, S.W. If a dealer has a new machine in his stoc which was purchased before the restric tions came into force he may sell thi machine without demanding a Class certificate from the purchaser. No licen is necessary for the purchase of a secon hand machine.

READER'S REPLY.

Scott Queries.

Referring to "C.P.A.'s" Scott queri in your issue of March 14th, my exper ence is that, for ease of starting fro cold, one or more injections of petr (or preferably ether) into the inductio pipe are usually indispensable. As Binks carburetter levers, the air lev should be closed and the throttle abo one-third open. With regard to t magneto, to test the timing according the makers' instructions, remove t sparking plug from the left-hand cyli der, and turn over engine until t piston is seen to be at the top of stroke. Now fully retard the igniti by rotating the contact breaker cov anti-clockwise, when the points should just separating with the fibre block the bell crank lever at the lower end the right-hand segment. If "C.P.A has further trouble with his Scott, a likes to communicate with me, I sh be glad to help him.—1914 SCOTT.

EXPERIENCES WANTED.

N.A. (Oakham).—4 h.p. A.J.S. fit with Amac or Binks carburetter. C sumption, speed, and hill-climbing ca bilities.

RECOMMENDED ROUTES.

ILIFFE & SONS LTD., 20, Tudor St., E.C.4.

IMPORTANT NOTICE.

Owing to the Easter Holidays, the issue of "The Motor Cycle" for April 4th, must be closed for press earlier than usual. All copy and instructions for Miscellaneous Advertisements in that issue must, therefore, be in our hands not later than first post on Thursday, March 28th.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

Alldays.

Driving Examinations and Certificates.

A CORRESPONDENT wrote to *The Motor Cycle* recently asking if it were not possible for him to obtain a driving certificate which would show that he was capable of driving a motor bicycle and had some knowledge of the theory of its working. The reason for this was that he had applied at a recruiting office to be enrolled as a despatch rider, and the officer in charge told him that he would do his best to put his case forward, provided he could bring some proof that he was a capable driver and had a good knowledge of motor bicycles. We were reluctantly compelled to tell him that no such certificate existed.

The car driver has no difficulties in this respect. There is the R.A.C. driving certificate, the examinations for which are extremely popular at the present time. The Royal Automobile Club is doing very useful work in holding these examinations daily. All sorts and conditions of both men and women go in for them. The examinations are divided into classes, for the first, second, third, and owner-driver certificates, the difficulty of the test being in proportion to the type of certificate for which the candidate enters. The examinations consist of a short but stiff driving examination, and for the first and second-class certificates a technical paper has to be passed.

It should not be beyond the powers of the Auto Cycle Union to institute something rather similar for motor cyclists. With the motor cycle, however, there is this difficulty, a solo machine cannot be very well observed, and this fact has certainly militated against the solo machine entering for certified trials. With the sidecar machine, on the other hand, the examiner can easily accompany the driver, but, of course, in the case of a solo machine it would be necessary for the examiner to ride in close company with the candidate on another motor cycle.

It would certainly be worth while for the Auto Cycle Union to adopt examinations of this kind, as the certificates, when procured, would be a valuable asset to the candidate should he desire to obtain employment as a motor cyclist either in the Army or in a civilian capacity. The attention of the Auto Cycle Union has been called to the matter in question, and we understand that it is receiving consideration.

Easier Decarbonisation.

ONE of the weaknesses of the air-cooled engine is that it requires to be much more frequently decarbonised than one which is water-cooled, and, furthermore, the carbon deposit in the case of an air-cooled engine is much harder and more difficult to remove than in the case of the water-cooled engine. The result is that the skilful owner-driver of a car can always make a fairly easy job of decarbonisation by scraping out the deposit through the valve ports.

Now in the case of a motor cycle engine there are two difficulties: one is the restricted area of the valve ports, which renders it difficult to get in a suitable tool, and the other is the fact above mentioned, that the carbon deposit is very much harder. The ordinary process of removing the cylinder is, of course, the most satisfactory method, but it requires a good deal of labour. On the other hand, the scraping process, though it cannot result in such a complete cleaning of the piston and combustion head, is quite satisfactory if carefully carried out at the necessary intervals, and renders the removal of the cylinder only essential about once or twice a year.

Many motor car manufacturers have realised that facilities for the scraping process are desirable features, and have, in consequence, fitted ports with detachable covers in the cylinders, through which scraping tools can be easily inserted. That is a point in design which we think motor cycle engine designers may well adopt.

An index to the advertisements in this issue will be found on the page facing the back cover

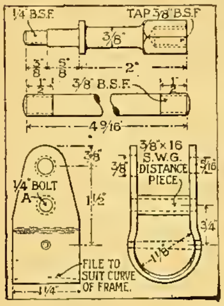
IDEAS: Useful and Ingenious.

Readers of "The Motor Cycle" are invited to contribute to this page any ideas successfully adapted to their motor cycles. Contributions will be paid for at our usual rates. Rough sketches will suffice.

ALTERING THE SADDLE POSITION ON A DOUGLAS.

THE sketch shows an altered method of fixing the saddle on a $2\frac{3}{4}$ h.p. Douglas 1915 model.

The saddle position, in relation to the footrests and handle-bars, on the machine as it was handed over to me was most uncomfortable. I was seated too far back, and the saddle was just too high from the ground to enable me to paddle off on anything but a slight down grade.

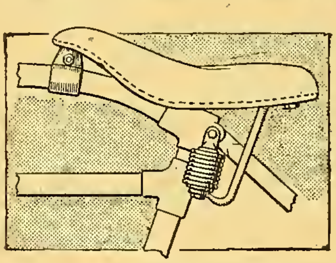


Dimensions of the parts needed for the alteration to saddle fixing of a Douglas.

The saddle clip was fixed on a straight tube—an extension of the rear frame tube, in fact—and although I could have moved the saddle forward by making a special pin, yet this would have been at the cost of increasing its height from the ground, which I was determined not to do.

I finally decided to alter entirely the method of fixing the saddle, to scrap the usual underframe, and attach the nose of the pressed steel frame of the saddle directly to a special clip located on the top tube of the machine and support the springs on extensions of a special seat-pillar bolt.

The result has entirely justified the trouble, and now the top of the saddle is only $28\frac{1}{2}$in. from the ground, and I can paddle off in comfort. In addition, I sit sufficiently far forward for some of my weight to be taken on the footrests, which, with a lightweight on a pot-holey road, means much easier riding.



Showing the alteration effected and the fitting of the clip.

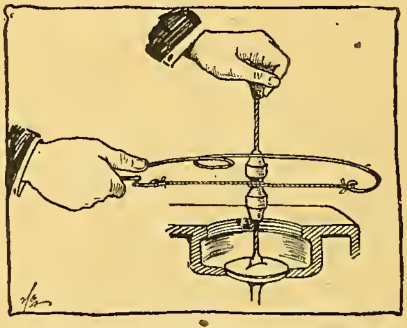
I see from recent illustrations in *The Motor Cycle* that an identical scheme is embodied on the 1918 model Douglas.

The dimensioned sketches show the actual new parts which had to be made. The only alteration to the saddle itself was reaming the fork ends to $\frac{5}{16}$in. at the top of the springs where they were attached to the old underframe, to allow them to rock on the new extension pieces, $\frac{5}{16}$in. in diameter.

In fitting the front clip on to the frame tube, care should be taken to drill the hole A so that the tubular distance piece bears hard on the top of the frame tube—in fact, I drilled mine about $\frac{1}{32}$in. low, and had to file a half-round groove in the distance piece before I could get the clamping bolt to enter. A $\frac{1}{8}$in. taper pin fitted right through the clip and the frame tube makes assurance doubly sure. —F.B.S.

A USEFUL VALVE GRINDING TIP.

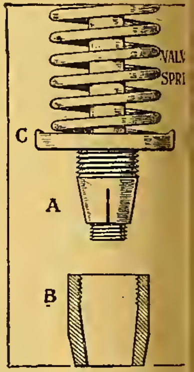
IN cases where a brace and bit cannot be used the rotational movement of the valve may be obtained by rigging up the device shown in the accompanying illustration. It is necessary to equip a screwdriver in the manner shown, that is to say, with a handle at the top end, which will allow the screwdriver-shaft to turn independently of it, and a pulley in the centre fixed solidly to the shaft. Then make a bow by looping round a piece of thick iron wire in the manner shown and loop the string round the pulley. By this means even pressure upon the valve, and an even movement in both directions can be maintained.—*L'Automobile aux Armées.*



A device for obtaining rotational movement when grinding in valves.

VARYING THE TENSION OF A VALVE SPRING.

THE following device shows how t tension of the valve spring can altered and the valve spring tak off without the trouble of holding up t spring while the cotter pin is taken out:



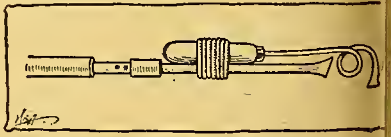
An easy method o varying the tensior of a valve spring.

The end of the valve stem is threaded, and on it is screwed the nut A, the top part of which forms the support for the spring. Below the support C the nut is threaded on the outside for $\frac{1}{4}$in., and the lower part is narrowed towards the end, and has four slits half-way up. The locknut B screws on to A and presses the lower part of A against the valve stem, and so locks it. To remove the spru unscrew the locknut B and then unscr the nut A.

The spring tension may be altered just loosening B, adjusting A the quired amount, and tightening up again.—G. R. More.

A HOME-MADE GAS SOLDERING IRON.

THERE is no more useful tool in t motor house than a gas solderi iron. One of these may be made the following manner: Procure a sm piece of petrol pipe, the end of whi should be flattened out; drill three sm



A home-made gas soldering iron.

holes at the opposite end, which shou be covered by means of a sleeve so to provide a means of adjustment for air; lash a file handle to the copper p by means of wire, and in this han insert a piece of thick copper wi making a spiral just in front of the of the copper tube, aud flattening end. The iron may be used with coal acetylene gas. The flat end of the provised soldering iron must be tinn of course, in the usual manner.—*L'A mobile aux Armées.*

OCCASIONAL COMMENTS

By "Ixion."

The Anti-cycle Carist.

PRESUMABLY we were not meant to take "R.H.B.'s" denunciations of cycle cars too seriously; as humorous exaggerations they were xcellent. Not a word in them would apply to such cycle car as a 1912 Morgan: *a fortiori* they will not pply to a 1920 four-wheeler: and he has only himself blame for investing in one of the less successful pes of machine which at its best was prematurely arketed. He may be interested to know that one of ur leading designers is seriously considering the pro- uction of a 20 h.p. four-wheeler, with its engine ounted on ash bearers, *à la* aeroplane, cable and obbin steering, and with a belt drive! The crying eed of this type of cycle car is a little attention from ukka engineers: in the past it was far too much of a ack street file-and-hammer job.

The Yankee Lilliput Car.

I WISH one of our readers in U.S.A. would send us some accurate description of the curious little cycle cars which American enthusiasts appear to building at home by ones or twos. They are minia- re duplicates, externally, of famous racing cars, d usually consist of the power plant of a big V twin cycle, mounted in a home-made chassis. In other ords, they are the private owner's conception of hat a Carden monocar tried to be as a manufacturing oposition. They rather appeal to me for winter ding. They have most of the merits of motor cycles, d none of their bad weather shortcomings. On the her hand, their cost is probably ridiculous, and will event their ever figuring as a production job. When get a little leisure and a few odd bits of tubing, I ink I must try my hand at one.

Stunt Two-strokes.

WE all know that from time to time a stunt two-stroke appeared in the flying mile type of competition, and put up a marvellous show. ome of us were puzzled at the failure of these henomenal engines to make a commercial *début*. he explanation of the mystery is very simple. They verheated so shamelessly that they could only be riven in penny numbers, and could not even travel a distant hill-climb by road. During the war, some their defects have been eliminated, and rather stounding discoveries have been made. For example, certain aero engine designer was persuaded to put is special knowledge at the disposal of one of the vo-stroke firms. He planned a special engine, which as a duplicate of their standard in every respect xcept that it possessed cooling factors designed on a asis of knowledge, in lieu of the rank guesswork hich formerly governed that special aspect of motor ycle production. The resulting engine, though of uite small capacity, will average 30 m.p.h. indefinitely with a sidecar attached, and evinces no tendency to overheat. I do not say that the other common failings of two-strokes have yet been eliminated. This engine does not two-stroke down to slower speeds than its predecessors, nor can it be used with any old sparking plug, nor does it register 100 m.p.g. But its performances prove that things are moving in the two-stroke world.

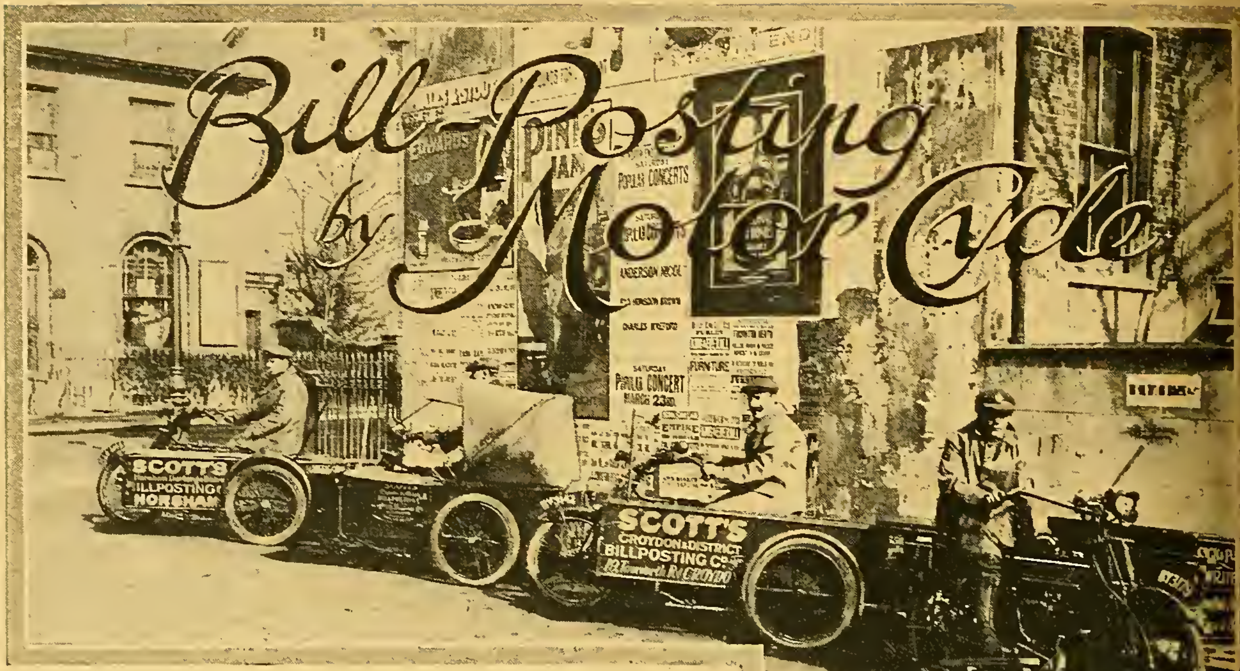
The Future of Two-strokes.

THE experiment detailed in my last paragraph has a peculiar interest to my mind. Technically, two-strokes are stagnant. Their manufacture almost entirely ceased four years ago, as they were not sufficiently developed to be useful for war purposes: and we might suppose peace would find them very much as they were in 1914. A single experiment has banished one of their main bogeys, and the transformation is due to deductions from research in a totally different sphere. I dare not say what the compression ratio of the engine under question is, because nobody would believe me. Anyhow, this solitary engine has helped one firm to see its way to make big air-cooled two-strokes which will be roadworthy. In addition to the increased power and perfect cooling, they have got rid of oil-cooling and can use a thick electrode sparking plug without sooting it every few miles, that, too, without getting four-stroking at low speeds due to over-lubrication. Give them twelve months of free experimental work in peace and they will evolve something interesting.

Comparing Consumption.

I WAS careful to state that comparisons between motor cycle and aircraft engines in respect of fuel and oil economy could only be approximate, and that I had no wish to press the estimated figures which I gave. Nevertheless, I have several remarks to make in answer to Mr. Brooker and others. The first is that it is perfectly fair to compare engines on the basis of the work which they ordinarily perform. So the consumptions of a motor cycle should be reckoned on, say, a trip from London to Brighton at an average speed of 20 m.p.h. and of an aero engine at its normal r.p.m. In the second place, if the mileage per gallon of light cars and motor cycles is mere guesswork, we can none the less absolve the aero engine from the charge of extravagance, because modern aero engines approach within about 10% of the maximum thermal efficiency now obtainable; nobody can assert that road engines come nearer that ideal. In the third place, something is to be learnt from the fact that precise fuel and oil statistics are valued in the aircraft industry by maker, buyer, and user alike: whereas no valid statistics have ever existed in the motor cycle or motor car trade. The sooner motor cycles and cars are manufactured and sold under stringent consumption standards, the better for us all.

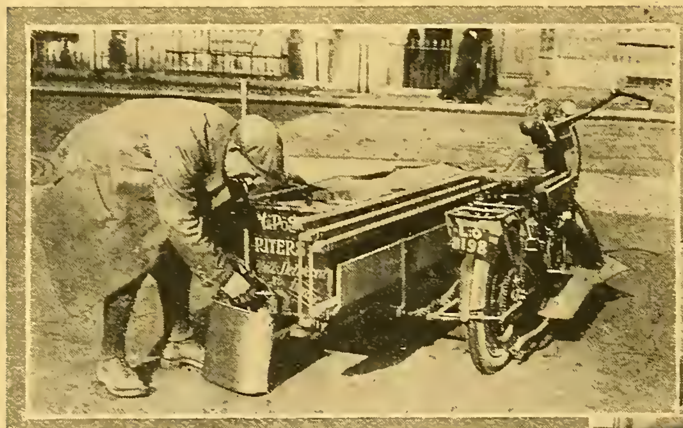
Bill-Posting by Motor Cycle



The four Enfield sidecars which have been of much value in the work of bill-posting in the outlying London districts.

Effecting Economy by Replacing Horses and Vans.

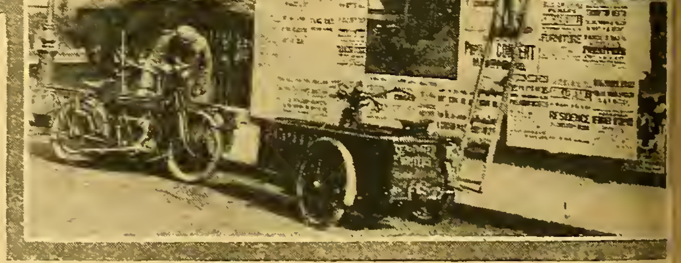
HOW the motor cycle may be made successful in business is clearly demonstrated by the following account of the work of a London bill-poster, Mr. A. Scott, who at the outset of war lost most of his men. Before hostilities began he employed eleven men, three horses and carts, and three handbarrows. He then started to use Enfield motor bicycles and sidecars, and can now carry out the same quantity of work with four men, each mounted on a sidecar combination.



The bill-poster's outfit, showing the paste tank at the rear, and the neat manner in which the ladder is stowed away

The first machine, which was purchased in 1914, covered 16,000 miles the first year it was in use, and one of these motor cycling bill-posters travels 125 miles a day, covering a distri extending from Streatham to Billingshurst, includi Epsom, Ewell, Leatherhead, Dorking, and all tow and villages in the neighbourhood. The man occupied in posting bills for auctioneers' announc ments, cattle sales, and undertaking all Governme posting in that locality. The special sidec bodies have been designed by Mr. W. J. Fla manager to Mr. A. Scott, advertising contract 19, Tamworth Road, Croydon.

The motor cycle and sidecar chassis are standard Enfield manufacture, but the body c sists of a hard wood frame with Venesta pane strengthened by angle irons round the top a down each side, painted with four coats of pa



l-posting by Motor Cycle.—

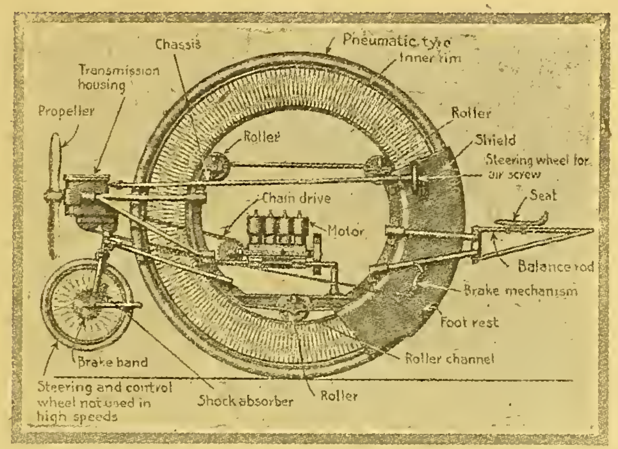
any desired colour, varnished, and lettered. The ar of the body is supplied with a galvanised iron k and a tap for the paste, while there is ample om for cans, brushes, and bill-posters' accessories. e centre portion is covered with a movable water- oof hood to keep the bills dry. The three-slide lder, which extends to 18ft., is carried in a special partition built out to accommodate itself to the shape of the ladder.

The amount of work done by these sidecar combinations gives a clear idea of how much labour and expense are saved by this method of transport. Mr. Scott assures us that even when the war is over he will never go back to horse transport, so satisfied is he with his new steeds.

THE MOTOR UNICYCLE.

Two Brain Waves from America—a 10ft. diameter Unicycle and a Gyroscopic Single-wheeler.

N the mechanical world, America is regarded as the home of freak ideas, gineering (?) nightmares d absurdities, but very ten the germ of a great ea is found in the speci- ation of the most fan- stic invention. For this ason America should be oud that it has men with eas, whatever their value, cause there is more merit originality than in pying..



A curiosity in American motor design. If a unicycle could be driven with a smaller resistance and at greater speed than a bicycle, if it could be built more economically or compactly or could be operated more safely or enjoyably, and if small air-screws could be made to apply an effective thrust against the atmosphere, the combination might lead to desirable results. But in each of these things it is inferior, and their combination multiplies the degree of inferiority to the motor bicycle.

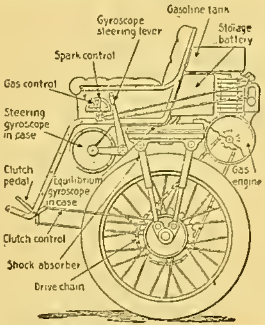
We illustrate on this ge two ideas emanating om America which aim the same end, *i.e.*, the oduction of a single-wheel otor cycle. As to whether ere would be any advant- e in a single-wheel motor cle it is difficult to say: any case, neither of the nventions" shown here pears to possess ad- ntages that would justify its production. Both, wever, are interesting, one because it illustrates how far some inventors will go in straining after originality, and the other because it embodies gyroscopes for balancing and steering.

A single wheel motor cycle, having gyroscopes mounted in vacuum cases to steady it. The bizarre idea is essentially American.

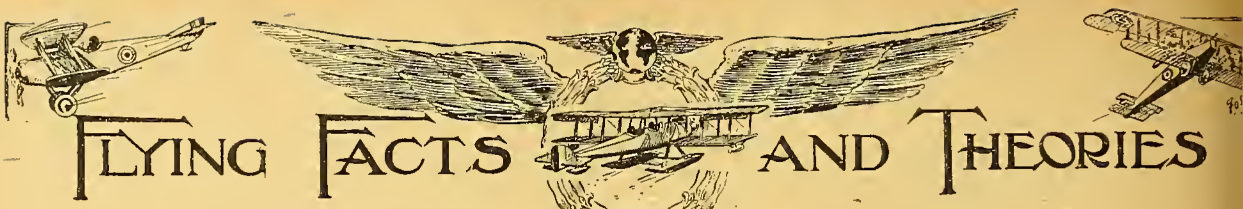
The first illustration depicts what can be described only as a mechanical monstrosity, and, at the best, the drawing was probably intended by its inventor to be nothing more than diagrammatic. It will be noticed that, judging from the relative positions of the sliding seat and the foot-rests, the wheel would be nine to ten feet in diameter, while, although the four-cylinder engine is presumably of the water-cooled type, no provision is made for the cooling of the water. What happens while the driver is climbing into his seat can be better imagined than described, but it is more difficult to imagine how such a contraption would be replaced in a vertical position after having fallen over upon its driver.

The other "invention" is a little more sensible. An electrically - driven gyroscope is intended to maintain the machine in an upright position, while a second gyroscope is installed on two bell crank levers to operate the steering. One would imagine that, if such a machine were got under way, it would be very unpleasant for the rider should the electrical connections short circuit or the accumulator run down while travelling at a high speed. Similarly unpleasant would be the tendency for the whole contrivance to revolve around the wheel spindle when increased power was needed to climb a hill, for then it would become a struggle between the power of the engine and that of the gyroscope. For this reason probably only a single gear is recommended in conjunction with a "gas engine," the bore of which, if the illustration is intended to be taken seriously, would be about 50 mm.

Referring to this design our American contemporary *Popular Science Monthly* says: "Imagine the sensation of racing down the road on a one-wheel vehicle! All the world is ahead, only the one wheel is beneath, and a man is free to career and career as much as he likes—or more! No wonder inventors experiment." But there's a wealth of meaning in that "—or more!"



Details of the gyroscopic single wheel motor cycle.



FLYING FACTS AND THEORIES

THE SPINNING NOSE DIVE.

By W. G. ASTON, A.M.I.A.E.

THE spinning nose dive is an aerial evolution which has in the past earned a particularly unpleasant reputation, although, thanks to intrepid experimenters and to modern methods of flying tuition, it has, of late, lost most of its fearsomeness, and is now freely indulged in by pilots of all degrees of skill. Like all other manœuvres, it is perfectly safe if carried out at such an altitude that recovery into straight flying is capable of being performed, but in the earlier days of aeroplanes reasonable altitudes were so rarely reached and the conditions of the spinning nose dive so little understood that it but rarely occurred without being followed by disaster, so that in very few cases could the experimenter give any information upon it to other pilots. Apart from that, it was then quite accidentally provoked instead of being carried out, as it now is, generally on purpose.

Do the Controls Change Places?

It is sometimes said that when an aeroplane rolls over through 90°, so that its wings, instead of being horizontal, are now vertical, the controls change places —that is to say, the elevator becomes the rudder and the rudder becomes the elevator. This is a loose sort of expression, but its meaning is clear enough. Strictly speaking, it is untrue, because the elevator is, in all circumstances, employed to rotate the machine about its transverse axis; similarly, the rudder always rotates the machine about its vertical axis, and it makes really no difference whether these axes adopt new positions or not. On the other hand, the idea of the elevator is inextricably associated with turning the machine in a vertical plane perpendicular to the earth, and the rudder with turning it in a plane parallel to the earth, and in this sense the expression is defensible. Suppose, for instance, that the machine is rolled over as shown in fig. 1, then to lift or depress the nose of the machine relative to the earth it will be necessary to use the rudder as an elevator. Similarly, if it is desired to turn the machine in a horizontal plane, this evolution will be performed by means of the elevator and not by the rudder. In the meantime, each canted organ takes effect about the same axis as formerly, only with the machine rolled over its vertical axis has become horizontal relative to the ground for the time being.

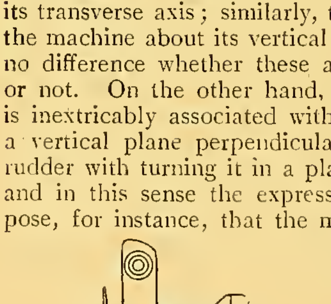


Fig 1.

How Knowledge was Acquired.

It is this fact, or rather because this fact was nc fully realised, that led to so many spinning nose dive ending in serious "crashery." The machine adop an attitude that the pilot is instinctively inclined t think can be corrected with the rudder, whereas it really the elevator which ought to be worked. Or historic spinning dive was performed by the late L Parke, R.N., at the Military Trials. He found him self hurtling towards the ground and spinning roun in a very narro radius, and he trie without effect to brin the machine straig by means of the win warping and th rudder. These ha no effect at al Within a few feet apparently certa death, and, of cours dealing with circu stances with whi he was totally u familiar, and for which he was equally unp pared, he resolved to try the elevator, although, he afterwards told me, he was quite certain it cou do no good. It immediately brought him out of t spin just in time to prevent a catastrophe, and at stroke the foundations of knowledge were laid as as the spinning nose dive was concerned.

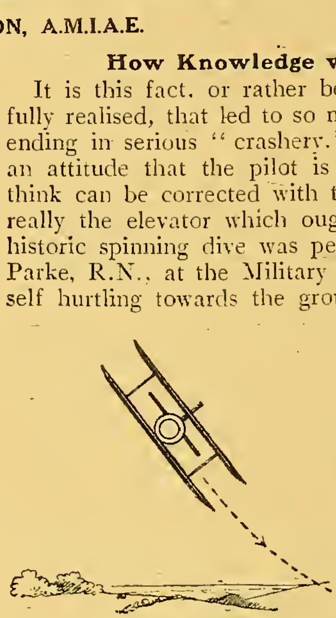

Fig. 2.

The Cause of Spinning.

Consider an aeroplane in the attitude shown in f 2. It is supposed to be flying towards the read If it be allowed to stall in this position it will tend correct itself by two actions; first by side-slippi towards its left to get on to an even keel, and secon by diving towards the reader, so as to acquire fly speed. A stable machine if left to itself will perform this recovery of its own accord.

If, however, the pilot pulls the stick towards him, and so sets the elevators at a negative angle, whilst the machine is in the position shown in fig. 3, he will partly tend to bring the nose of the machine up and partly make it turn to his left. This will entirely

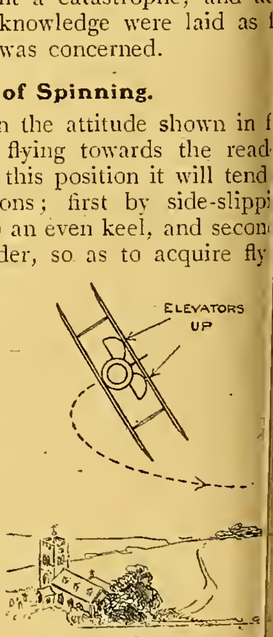

Fig. 3.

ing Facts and Theories.—

feat the natural recovering action of the aeroplane, d in most cases in these circumstances it will imme-ately spin. Since the machine will have now rolled er at such an angle that the elevator and rudder ve almost entirely interchanged their functions, the dder will make very little difference indeed. If eft" rudder is applied it will simply make the chine tip its nose down and dive quicker; if put to the right it will increase the diameter of the in, but will not bring the machine out, since its action this direction will be overwhelmed by the elevator. Also since the angle of incidence of the main planes ll be now very big indeed, something like 60°, the erons will have no appreciable effect at all in aightening the machine up.

How to Straighten Out.

Recovery can only be made by pushing the stick rward. Once the elevators are set at a positive neutral) angle, the tendency for the machine to ep turning in a horizontal plane is removed, and, if ble, it can be then left to recover itself, or simul-neously with pushing the stick forward the right dder can be applied and the aeroplane quickly ought on to an even keel. Once it is allowed to me out of the spin the ailerons can be brought into tion for straightening up purposes.

Some machines are difficult to get into a spin, and ers easy. In general, however, the royal road to nning is either to bank the machine well over and dder outwards instead of inwards, or to stall the chine when partially banked by pulling the stick vards one.

The impression in a spinning nose dive is that the tre of the spin is somewhere not far from the axis the machine, but in most cases this virtual centre well outside the inner wing tip, though on some chines it can be brought within the span. The fact that incidentally the earth seems suddenly to have gone completely mad is not calculated to assist a pilot thinking clearly when spinning for the first time.

The Use of the Spinning Nose Dive.

Fig. 4 shows the evolutions diagrammatically. The dotted lines indicate the path which the machine would normally take if allowed to side-slip and finally dive straight forward. In the course of this side-slip the fin, of course, will tend to straighten the machine up and cause it to meet the relative wind head on. The negatively-inclined elevators, however, act as rudders and force the aeroplane to take the path indicated by the unbroken line. Whilst spinning, the controls can all be in a central position (except the stick, which will be pulled back, though not over to either side), and the bubble instrument may also give a neutral reading.

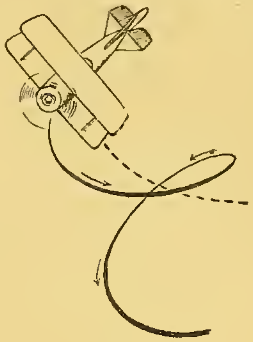

Fig. 4.

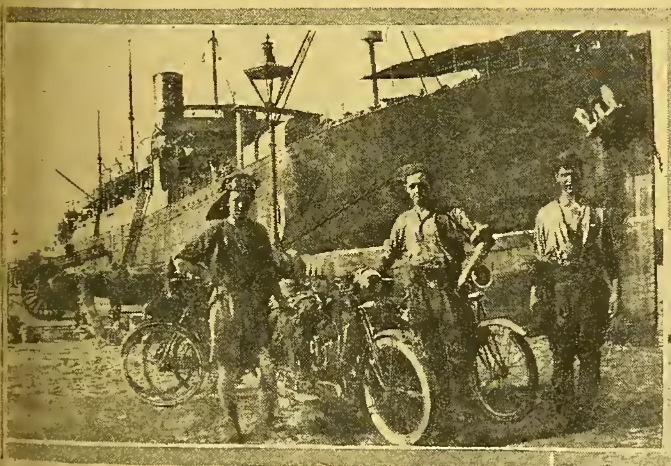
A Vertical Descent.

The machine will be heavily stressed, and the pilot will feel that he is being forced down on to his seat by a tremendous pressure, sometimes to such an extent that he will be unable to lift his foot from the rudder bar. Altitude will be lost at a deceptively rapid rate, and it is this fact that makes the spinning nose dive a very valuable evolution, since by its means a pilot can descend from any height to a landing ground practically vertically beneath him, and at a rate of descent which he could not equal by any other means.

SCENES IN THE NEAR EAST.



(Top) Despatch riders on the quay at Alexandria.

(Bottom) On the bank of the Suez Canal. In the district in which the photograph was taken there are good stretches of roadway, and it is an agreeable change for the despatch rider to be able to let out his machine for a good spin on top gear after the perpetual second gear work in the soft sand of the desert.

Cpl. Webb, who sends us the photographs, speaks well of the way the gears of the Triumph and Douglas motor cycles have stood to the hard work entailed in despatch work in Egypt and Mesopotamia.

The Munition Worker and his Petrol.

Impressions at a Meeting of the National Motor Cyclists' Fuel Union.

IT was with a perfectly open mind that we attended a recent meeting in Coventry of the National Motor Cyclists' Fuel Union, and, we confess, we felt a stranger in a strange land, for it was not a meeting of motor cyclists such as we have been accustomed to attend.

Where were the care free boys of all ages, who risked their necks for a medal in times of peace? we asked ourselves, as, glancing around the large and crowded room, we realised that this was no protest against conditions of sporting competition framed by men wiser than themselves. It was a protest against conditions imposed upon them, and all motor cyclists, by those in whose hands lies the safety of the nation.

In place of the genial faces of the sporting motor cyclist we saw grim men—young men mostly, some very young indeed—with toil printed deeply upon their features: the workers instead of the players, and the motor cycle assumed an importance beyond that of the mere pleasure machine. These men knew the motor cycle as a utilitarian machine. It was their bridge between home and work. That bridge had been taken from them, and the *détour* necessary on that account was sometimes long, sometimes inconvenient, and always unpleasant. They considered they were entitled to an allowance of petrol to permit them to travel to their work, to go home occasionally, and, we were sorry to hear, for recreative purposes.

Petrol for Recreation.

Those workers who ask for petrol for recreative purposes certainly consider they are entitled to use their machines for the sake of their health on account of the nature of their work and its value to the country, but we think the same justification, if such exists, may apply equally to many others who are not connected directly with the production of armaments. The question at the moment is whether the benefits derived are as nationally important as the amount of fuel so consumed.

As we have pointed out in previous issues, if every motor cyclist in the country were allotted two gallons per month, the annual consumption would require but one-eighth of a cargo of a tanker.

But why has the Government appointed a Petrol Economy Officer, whose duty it is to prevent waste not only among the civilian users of fuel, but also in the Services? Why should another officer be sent to France, into the very war zone, to carry out the same work, and how can the saving of a few gallons here and there affect the general situation when such huge quantities are involved.

There must be a reason, a necessity, for the Government's action; and this reason may be found allied to the food and shipping shortage.

Because the Forces consume millions of gallons of fuel is no reason why civilians should use even a few hundred gallons unnecessarily, because *the carriage of one gallon of fuel involves shipping space which could be used for material to make five 2 lb. loaves of bread.*

The question for the members of the N.M.C.F.U. to decide is whether they are fully justified in using cargo space for 20 lb. of bread per month. We think that no man who asks for petrol for recreative purposes can satisfy his conscience on this point.

Renewed Permits to be for Nine Months.

Mr. A. W. Torkington, of the A.C.U., and chairman of the Fuel Union, made several interesting observations at the Coventry meeting.

He reported "very satisfactory" progress. Every genuine case from the provinces put forward by the Union had been granted petrol supplies. In London the Union had not been so successful, owing to the number of other means of transport available.

Mr. Torkington said it was the object of the Union to obtain two gallons per month for every member of the Union who resided two miles and more from his work, and, provided their cases were genuine and deserving, he had no doubt that permits would be granted to all eventually.

Personally, we think no case is "genuine" where a man lives only two miles from his work. One is constrained to ask whether the majority of workers lived any nearer to their work before the possession of a motor cycle was within their means. Our impression from the debate which followed the addresses was that these men resented their masters and managers using cars while they were compelled to trundle a pedal cycle. Many cases were mentioned—almost spitefully, one is bound to say—and Mr. Shrapnell-Smith, the Petrol Economy Officer, who addressed the meeting, ask the members to let him have particula of specific cases, when he would invest gate them. Yet these men were aski to be allowed to do the same thing, a they gave one the impression that, whi they considered they were entitled to u petrol to get to their work, those mo fortunate than themselves should not ha the privilege.

Mr. Shrapnell-Smith, in reply to question from a member, said it w impossible to apply rationing to t Services. It struck us as ludicrous th these motor cyclists who asked for pet for recreative purposes and to get their work, when it had been prov that they could do without it if it w really necessary, should suggest rati ing the petrol to those who are keepi from them the horrors of warfare.

Inconsistencies.

Surely by such inconsistencies, it impossible for the Union to retain long the sympathies of the Ministry Munitions, the Petrol Controller, the Home Office which it has at present time.

Another point which appeared to us tending in the same direction was remark made by Mr. Torkington to effect that efforts were being made interest the various branches of A.S.E.

Mr. Torkington appealed for a stro membership. At present there w 3,000 members; but, he said, he war to be able to speak for 10,000 memb when it would be easier to get concess *to enable munition workers to use t machines for the benefit of their healt*

Since the objects of the Union supposed to be national and patriotic is trite to say that the more mem the Union obtains the less patriotic becomes.

Mr. Torkington advised the mee that between three and four thous munition workers had been gra licences within the past two or t weeks, from which one may gather munition workers *are* being given ferential treatment, and that if members of this community are to ob full supplies, then the Restriction O No. 2 becomes not a means to econo fuel, but merely a redistribution sch under which an almost new "crop" motor cyclists benefits at the expens motor cyclists generally.

RECRUITING WORK BY AN AMERICAN MOTOR CYCLE FIRM.

THE Harley Davidson Motor Co. are making a great effort to secure proficient motor cycles for military duty, and have sent out the following letter to hundreds of motor cyclists in U.S.A., in an endeavour to attract men for the army.

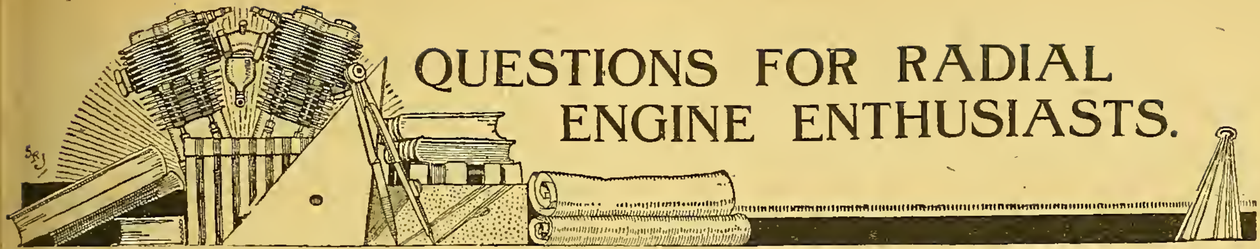
"The motor cycle is playing an increasing part in the present world-war; the Government is recognising the need of men with specialised training for motor cycle duties, and is giving motor cycle mechanics preference.

"The first unit of the mechanical repair shop for Overseas service, which includes a motor cycle unit, is being formed in Washington. Capable men are and will be needed as motor cycle mechanics and in training schools. Several Harley-Davidson dealers and dealers' mechanics are already in the motor cycle service.

"This service offers an excellent opportunity for men with mechanical ability, and we advise all motor cycle mechanics who are subject to the draft or willing to enlist, or are alread service, to file applications with us.

"Harley-Davidson readers and chanics already in military service sh file applications, regardless of the that they are in the service.

"If you are personally subject to draft and wish to file your applic with us, we shall, on request, ho until such time as you may specify is apparent that all who are subje the draft will be called for service tually."



QUESTIONS FOR RADIAL ENGINE ENTHUSIASTS.

Will the Radial Engine ever become Popular on Motor Cycles?

BY AN AMATEUR DESIGNER.

I BELIEVE there are some people who have the idea that the only writers entitled to contribute to technical journals are those who happen to be acknowledged experts in their particular subject. For instance, according to this theory, no one should be allowed to write about engine design except notabilities of the type of Mr. Coatalen, Mr. Scott, or Mr. Bradshaw. Now this is a totally wrong notion, for at least two reasons. In the first place, gentlemen who are as talented as those I have named have something better to do than merely to write articles about designing; they can spend their time much more profitably in actually designing engines. Besides, one of the chief functions of *The Motor Cycle* is to enlighten its readers on all matters that fall within its compass, and unless its patrons were allowed from time to time to betray their need for enlightenment, as I am now about to do, it would be difficult to determine which form of technical knowledge was most in request. Anyone who is expecting one of those "authoritative" or "informative" articles, therefore, need read no further; my object is not to impart information, but to solicit it.

What I wish to elicit are some sound reasons for the hopes that are held out as to the possibility of adapting radial engines to motor cycles. As far as one can judge, the reasoning hitherto followed is that since radial engines for aeroplanes have certain advantages over other types of motor, they will be even more conspicuously successful for motor cycles. Hence all that need be done is to enshroud the proposal in a sort of rosy glow of optimism, to reiterate in buoyant tones, "Radial engines are *bound* to come"—and to leave it at that. Personally, I do not find much ground for confidence here; I should like to know a little more clearly just what kind of a thing the motor cycle radial engine is going to be, if, and when, we get it. By the use of a little mathematics one can attempt a rough forecast of the characteristics of such an engine; and then it rests with its upholders to point out how practical considerations are likely to affect the theoretical conclusions that I shall reach.

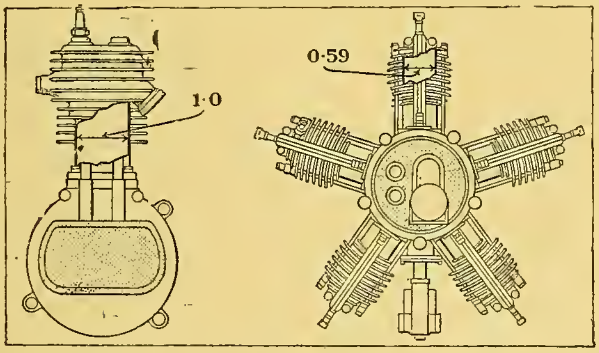


Diagram showing comparative size of single-cylinder vertical engine and five-cylinder radial engine of equal total cylinder capacity.

Pros and Cons.

By way of giving the radial a good start we will deal first with

(*a*) COOLING.—For purposes of comparison, a single-cylinder engine and a five-cylinder radial of the same total capacity will be considered throughout. Then the corresponding cylinder dimensions will be in the ratio $1 : \frac{1}{\sqrt[3]{5}}$, or $1 : 0.59$, as shown to scale in the sketch. Now the cooling area is obviously proportional to the *square* of the linear dimensions. Therefore, if the cooling area of the single-cylinder be represented by 1, that of the five small cylinders will be $5 \times (0.59)^2 = 1.71$. It follows that the radial will unquestionably be the cooler running engine of the two.

(*b*) WEIGHT.—If the cylinders, pistons, valves, etc., of the radial were exact reproductions on a smaller scale of those of the big single-cylinder—that is, if all the dimensions were merely reduced in the ratio 1 : 0.59—then the five small sets of parts would weigh in the aggregate just the same as the one large set of parts. But this exact proportion between corresponding dimensions cannot be maintained in practice. For example, the cooling fins on the single-cylinder are already cast as thin as they can be, and so it would not be possible to make them any thinner on the radial cylinders. Again, the metal in the pistons of the small cylinders could not be reduced materially in thickness below that of the large piston. Certainly the five sparking plugs of the radial engine would be very much heavier than the single plug required by the opposing design. There can be little doubt, then, but that the total weight of the specified components of the radial will be greater, and not less, than the corresponding figure for the single-cylinder engine. When we come to the crank case the position is obviously reversed, as a glance at the sketch will show; and if the reduced weight of flywheel called for by the radial be taken into account, it cannot be denied that on overall weight the radial may possibly have the advantage. I think it ought to be pointed out, however, that conclusions drawn from aeroplane practice in this respect are apt

Questions for Radial Engine Enthusiasts.—

to be misleading. A radial aeroplane engine sometimes makes such a good showing on a weight per horse-power basis because it is contrasted with a water-cooled vertical machine, in which the weight of the engine includes also the weight of all the water-cooling gear. In the present comparison the vertical engine suffers from no such unfair handicap.

Cost, Economy, and Balance.

(*c*) COST.—As far as an amateur can judge, the single-cylinder engine has it all its own way as far as production costs are concerned. Considering first the cylinders and similar parts, the ratio of the total areas to be machined in the two engines will be roughly the same as the ratio of the cooling areas, *i.e.*, 1.: 1.71. Since the machining allowances cannot be reduced in the radial engine components, we see that their machining involves the removal of nearly double the metal that need be tooled in the single engine. Although the radial crank case is smaller, it looks to me a more costly job to machine than the corresponding component in the "single." The increased expense necessitated in viewing, assembling, etc., five parts instead of one requires no demonstration.

(*d*) ECONOMY.—The radial will be more expensive to run, as well as more expensive to buy, for I do not see how its overall efficiency can possibly equal that of the single. Assuming the work wasted in friction between the piston and cylinder walls to be proportional to stroke × circumference of piston, that is, to the square of the linear dimensions, we see that the loss in the five radial cylinders will be 1.71 times the waste in the one big cylinder. It is a little difficult to see how the figures for the rotating parts will work out, but I have little fear of anyone being able to prove that the radial has advantages that will counterbalance its shortcomings in respect of piston friction.

In theory, at any rate, compression will be more reluctant to live contentedly in a radial engine than in a single. Taking piston leakage alone, the chances of the gases escaping may be taken as proportional to the total piston circumferences, that is, as $5 \times \pi \times 0.59$ for the radial to $\pi \times 1$ for the single, or as 2.9 to 1. Poor compression means high petrol consumption.

(*e*) BALANCE, ACCESSIBILITY, SIMPLICITY, TORQUE.—No contest is necessary here. as there is no comparison between the two types of engine in these respects. Either one or the other is hopelessly outclassed, according to the particular quality that is selected; we will therefore call honours even.

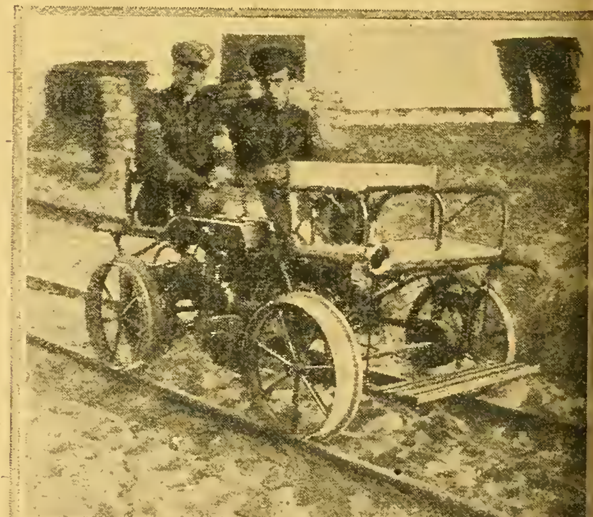
Inductive Reasoning.

Just as this problem lends itself well to mathematical methods, it seems to me to be peculiarly susceptible to the inductive method of reasoning; that is, by arguing from the known characteristics of one and two-cylinder motor cycle engines to the, at present, unknown properties of five and seven-cylinder power units. For instance, if an actual twin engine is found to be lighter than a single of the same capacity, then we can reasonably hope that the projected five-cylinder radial will be lighter than the twin. Or if experience shows that a single is cheaper to build and to run than a twin, then it is hardly likely that a radial will be anything but dearer. This method, therefore, is simply a matter of collecting and comparing facts. Information would be particularly valuable that related to engines produced by the same firm. Frequently a single and a twin of identical capacity are built in the same factory; could not comparative figures for such engines be published.

Facts Wanted, not Opinions.

The next move lies with the radial engine devotees themselves. If they do not make good their case now it will not be for lack of opportunity. Those who revel in elliptic integrals and differential equations of the third degree can assail my mathematics; while those of the hardened rider variety can relate their experiences with various classes of engines. But be it noted that it is facts, and not opinions, that are wanted. Petrol consumptions should be stated in terms of pints per hour (to three places of decimals) and not in terms of tankfuls and bulbfuls. Horse powers, too, should be the results of brake tests, and not of ascents of hills at estimated speeds, the gradien being assumed and the following wind ignored.

One other thing I should like to be satisfied about i the use to which the motor cycle radial engine is to b put. If it is merely to be embodied in 12 h.p. machine with the object of sweeping the board at race meetings, my interest in the proposal is at an end. M view is that if 2¾ h.p. motor cycles are found t meet the needs of D.R.'s, they should suffice fo carrying civilians to the seaside on a Saturday afternoon; while 5 h.p. sidecar outfits that are good enough for transporting machine guns should satisfy even th Best Girl in the World. Possibly, however, the ide is to take advantage of the lightness, even torque and excellent balance of the radial engine to produc diminutive units that will perform the same service a our present mounts at far less cost. I will enrol myself as a radial engine enthusiast if it will assist in th evolution of a motor cycle scaling 70 lb. all on, havin a single-geared engine of 1½ h.p., and a half-gallo tank good for a hundred miles run at one filling.



ON A METRE-GAUGE RAILWAY IN EGYPT.

A Triumph motor cycle built as an integral part of the chassis by the Egyptian State Railway workshops.

Steering and Stability of Single-track Vehicles.

INTERESTING CONCLUSIONS REACHED BY MATHEMATICAL PROOF.

The following notes on the stability of motor cycles are taken (as promised in our issue for Feb. 14th) from an article written by Mr. Geo. S. Bower, which appeared in "The Automobile Engineer" for October, 1915. It should be noted that all the statements and conclusions are proved mathematically in the article from which they are taken, and our scientific readers are advised to refer to this article if they wish to pursue the matter further, when they may rest assured of finding much to interest them. We regret that space does not permit of our printing the whole argument.

T is proposed to consider certain of the dynamical principles involved in the steering of two-wheeled vehicles, more particularly bicycles and otor cycles, and to show the effects of various factors the roadworthiness and security of the machines. ecial attention will be directed to the gyroscopic uples acting on a bicycle, and it will be shown how ne of these may be utilised to assist in the balancing the machine.

The steering and behaviour of a bicycle are very ich affected by the state of the road surface, ecially as regards its frictional qualities, and, in first place, it will be assumed that sufficient friction sts between the wheel and the road to prevent side-.

Forces and Couples acting on a Bicycle in Motion.

So long as a cycle is moving horizontally in a aight line, with its longitudinal plane vertical, the ly forces acting on it are its own weight vertically wnwards, with the resulting vertical reaction of the ud, the resistance to motion, and the propelling re-ion of the road. All these forces are in equilibrium, d there is no tendency for the bicycle to fall or to viate from its straight path.

Should its centre of mass be displaced by some ans to one side of the vertical plane through the e joining the points of contact of the wheels with road, gravity has now a moment about this line, d the displacement of the centre of mass will rease unless this gravity moment be counteracted.

This is done by turning the front wheel towards side of falling, this action counterbalancing gravity moment in two ways—first, by the fact at the path of the cycle is changed into a curved e having its centre of curvature on the side of lling, the centrifugal force thereby induced forcing centre of mass back to its normal position; ondly, owing to the precessional motion of the front d rear wheels creating a gyroscopic torque, assisting centrifugal force to recover the balance of the chine.

For the same weights and gyroscopic qualities in h case, a high-built cycle will lean over at corners less than a low-built one, but the angle of lean will always be greater than that of a bicycle unsubjected to gyroscopic torques. The Scott motor cycle, which has a very low centre of gravity, has excited much comment during the T.T. races by the sensational manner in which its rider leaned over when cornering. Doubtless the speed at which it took corners was higher than that of many other machines, but not so much higher as one might conclude from the angle of lean.

Before leaving this section of the subject it may be as well to remark that "castoring" the front wheel has no effect on the angle of lean, but only influences the torque exerted by the hands to maintain the cycle in its circular course. The effect, if any, of the wheels being out of track will be to reduce the angle of lean required at a given speed, owing to the cycle tending to fall about an axis not at right angles to the supporting torques, which act in planes at right angles to the wheels.

Skidding or Side-slip.

The above conclusions are based on the assumption that the friction between the wheels and the road is sufficient to prevent the machine from slipping sideways under the action of the centrifugal force when rounding a curve. When this condition is not satisfied, the equilibrium of the bicycle (both theoretically and actually) becomes a very complex matter.

On a wet surface the friction between the wheel and the road no longer obeys the laws of solid friction, but is rather similar to a lubricated bearing, in that the frictional force is *not* directly proportional to the weight causing friction.

Thus the increase in centrifugal force due to increase of mass is greater than the corresponding increase in frictional resistance, so that a heavy machine is more likely to skid than a light one, other things being equal, *i.e.*, assuming the heavy machine is not fitted with such narrow tyres as to bite through the greasy film. Again, the effect of moving the centre of gravity towards the rear, say, is to increase the centrifugal force on the rear end of the machine without a corresponding increase in the frictional resistance of the rear wheel, thus tending to cause skidding of this wheel.

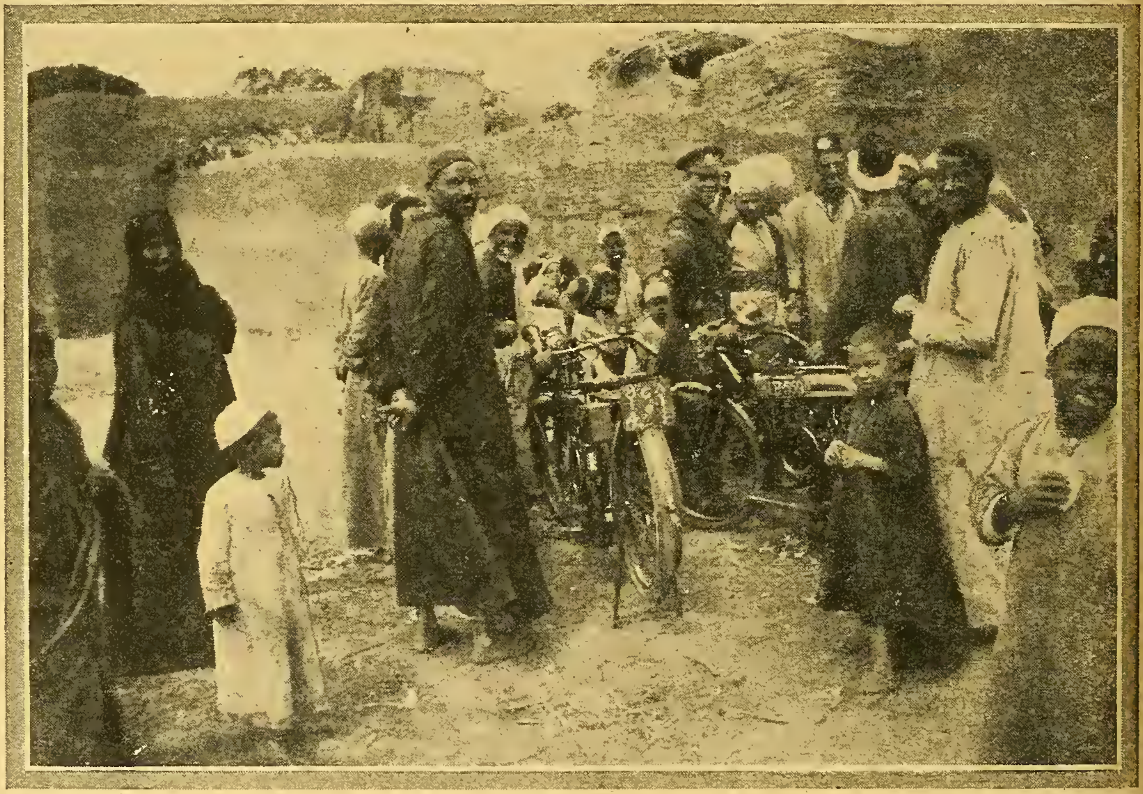
Steering and Stability of Single-track Vehicles.—

From the foregoing remarks, it will be obvious that, for the preventing of skidding, weight is best placed near the middle of the machine, and this points to the desirability of using a countershaft as against a hub gear, and of stowing luggage amidships on the footboards instead of on the carrier.

It is, of course, essential that the centre of mass shall not be so far forward as to cause the front wheel to skid, this being very much more dangerous than the skidding of the rear wheel, whilst sufficient weight must be placed on the rear wheel to prevent its slipping circumferentially. This circumferential slipping greatly facilitates side-slipping, and so is to be minimised by arranging the engine torque to be as even as possible. This again points to the advantages in this respect of belt over chain drive, the peaks of the engine torque curve being absorbed by slip and stretch of the belt instead of by slip of the tyre on the road, as in the case of an ordinary chain drive unprovided with any cushioning device. The two-stroke engine with its even torque, of course, scores heavily in this respect. The effect of sudden application of the rear brake i bringing the machine round is well known. Wha happens is as follows. Suppose the cycle to b travelling in a curved path and the brake to be applie to the rear wheel. The centrifugal force is now abl to move the rear wheel radially, and the angle of lea is made too large. To counteract this the rider steer towards the centre of curvature, thus still further increasing the centrifugal force and the tendency t side-slip. Unless the brake is released, the cycle wil turn round or fall sideways.

Before concluding this section, the author woul like to say that a set of experiments by some independent authority on the frictional resistance to side slip of various types and sizes of non-skid tyre tread on various road surfaces would be of extreme valu and interest. In the absence of experimental evidence the author can only say that he *believes* the total resis ance to side-slip to be the sum of two terms—one function of the weight (as in solid friction) and th other a function of the velocity (as in fluid friction).

(To be concluded.)



Despatch riders in a village in Egypt. The motor cycle is always a centre of interest to the natives, and in this instance the camera also appears to afford some amusement. Note the curious lettering on the number-plate of the Douglas.

HOME PRODUCED PETROLEUM.

READERS will remember that we have recently dealt with the question now under the consideration of the House of Commons, of boring for petroleum in Great Britain. The matter has been on the *tapis* for some six months, and now, according to rumour, it has once more been brought to the front, and the Parliamentary Secretary to Ministry of Munitions recently stated that negotiat with three different firms were practically comple and it was hoped that some of these firms would s be at work within certain definite areas over wl they would have exclusive rights.

MODERNISING AN OLD MOUNT.

Bringing Up-to-date a Ten-year-old Motor Cycle.

ALTERATIONS and rejuvenations to old-fashioned motor cycles always have an interest to those whose ans do not run to the purchasing of w or expensive second-hand mounts, d this account of the modernising of an d Quadrant may contain information eful to those who possess out-of-date chines. The details of the alteration e as follow :

ting Magneto in place of Accumulator Ignition.

The half-time shaft carrying the com- ed cam for the exhaust and ignition s drilled and tapped, and an extension ed long enough to reach through the ing gear cover, which was bushed to ry it. A sprocket for the chain was ed to the outer end of this extension. platform was made of sheet brass and lted to the engine lug behind the linder to carry the magneto, and a eet iron chain cover made and fitted enclose the driving chain. The gneto is a Simms lightweight model d has given every satisfaction.

Lubrication and Frame Alterations.

The alteration to the tank for the st and Lloyd lubricator was simple, a new hole was cut on top of the k to fit the pump, and the old hole the side of tank sealed up.

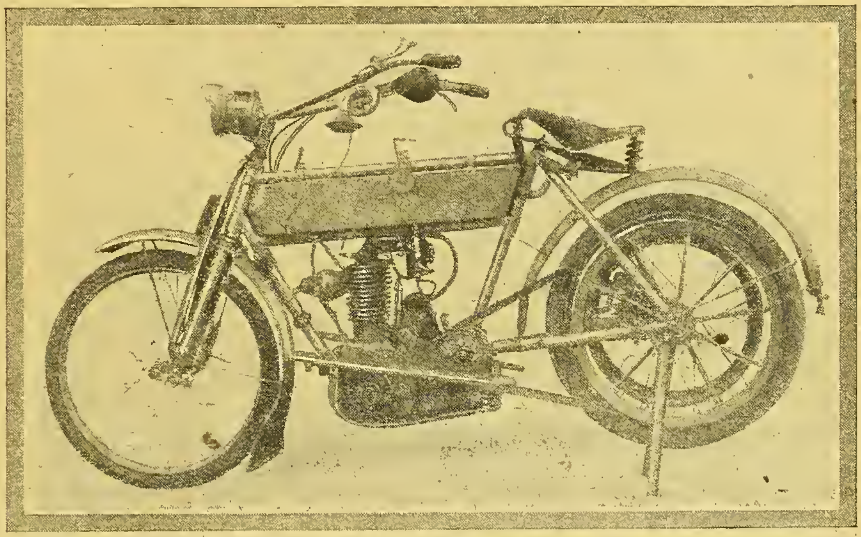
The pedalling gear was removed en- ely, and the bracket shell used to ld the fixed spindle for the counter- aft. The bolt holding the front engine tes to the frame lug was replaced by bolt long enough to form a support both sides for the front end of foot- ards. A strip of steel was bent up form a hanger over the chain stays frame for the rear end of footboards.

The brake pedal on the near side was mounted on a spindle pivoted through the back engine plates and carrying a second lever on the off side. This second lever actuates a double pad compensating brake working on the old belt rim, which was rebuilt into the off side of the new wheel.

Transmission.

The back and chain stays were replaced by stouter gauge tubing, and made wider to take the three-speed hub. The countershaft was made of a back hub shell mounted on the fixed spindle in the bottom bracket. This spindle also carries the clutch pedal on the off side. An adjustable pulley was brazed to this hub shell, and a chain ring bolted to the fixed flange of the pulley. A small chain sprocket was then mounted on the engine-shaft in line with the large chain ring.

The completed machine has been driven two or three thousand miles with sidecar attached, and is a very comfortable and docile mount, although not capable of high speed.



A 1908 3½ h.p. Quadrant, which has been modernised by fitting a three-speed gear, drip feed lubrication, two-step drive, footboards, and several other improvements.

New Arterial Main Roads for England ?

An American Promise of Perfect Roads for England after the War.

ACCORDING to an American motoring contemporary, there is on foot a scheme for the construction of an tirely new main road system for gland. No one in this country seems know anything about the scheme, but r go-ahead cousins have it as an absolute rtainty that the scheme is in course of eparation for execution after the war, d go so far as to give the full details to how the scheme looks on paper and w it will look in actuality.

Traffic Regulations.

A beginning is to be made with a road m Southampton to London, and from ndon to the North-West (passing rough the Midland manufacturing strict), and so linking up the capital th a vastly improved road communi- tion to the great Southern and Northern rts (Liverpool).

The roads are to be of not less than 150 et in width, and will be divided into ctions, each of which will accommodate affic moving in only one direction, and there are to be no fewer than five sections, presumably there is to be some distinction between the various types of traffic. If this is the case, we beg respectfully to ask our American cousins to have the centre path reserved as a glorious speed-way for motor cyclists. We shall then be able to open our throttles wide at Southampton and never dream of touching them again till we see the dome of St. Paul's, and, having filled up our tanks, we shall then be able to repeat this pleasant performance as far as, say, Coventry, and so on to Lancashire, which looks like getting something in the way of civilised roads before the crack of doom after all. If the new scheme does nothing else but equip with real roads this unfortunate county it should be fully justified.

Tapping Large Towns.

No large towns are to be tapped by the roads directly, but will be reached by branch roads that will tap the new "stunners" only at certain well sign-posted and well guarded points. The roads are to be constructed without regard to existing roads. If the Yank does anything at all, trust him to see that the scale is all right, but when an existing road fits in with the scheme of a new one, then the mighty potentates who have the matter in hand may deign to use the former specimen of the King's highway as a nucleus for the supreme path.

All this being as it is, who will say that the war will have been fought in vain?

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

Motoring in France.

The restrictions on private motoring in France are being very much increased. Only a small minority of private citizens are being granted driving licences.

Fuel.

In *The Autocar* of June 5th, 1915, a trial of a new motor spirit known as Natalite was described. This fuel consists of ether and alcohol extracted from waste molasses, and it is of great interest to know that the distillation of this fuel in South Africa has now reached the production stage.

Middlesex Motor Volunteer Corps.

This corps is anxious for motor drivers to assist in the valuable work of transporting troops on leave between the various railway termini in London. Any reader who can possibly volunteer his services is earnestly requested to apply to the Headquarters, 11-12, Silver Street, London, E.C.2.

The Cycle and Motor Trades Benevolent Fund.

At a special general meeting of the committee of the above fund, it was decided that motor hirers should be admitted to the benefits of the fund. To qualify for membership, the hirer must own at least two cars and derive his livelihood entirely from the motor hiring business.

The Formation of a New Centre.

A new branch of the body is shortly to be opened at Newcastle-on-Tyne, and the date for the public meeting will shortly be announced. It is possible that the opening of this branch will be followed by two fresh branches in other northern towns.

The Institution of Automobile Engineers.

The seventh ordinary general meeting of the Institution of Automobile Engineers will be held at the Royal Society of Arts, John Street, Adelphi, W.C., on Wednesday, April 10th, at 7.30 p.m., when Capt. Philpot will read a paper entitled "Some Experiments with Notched Bars." Cards of invitation to the meeting may be obtained on application to the Secretary of the Institution of Automobile Engineers, 28, Victoria Street, S.W.1.

Tyre Prices.

An increase in the price of tyres is probable; consequently, any motor cyclists who are in need of new tyres are advised to obtain them as quickly as possible.

Use of Coal Gas.

In view of several recent prosecutions for the illegal use of coal gas, it may be as well to remind readers that this substitute now comes under exactly the same restrictions as petrol. There is certainly the minor difference that if a permit can be obtained for the use of a motor vehicle the amount of gas that is used is not restricted, but the permit for using the machine is just as necessary if the machine is to be run on coal gas as if it is to be run on petrol.

Short Leave Petrol Licences.

In view of the number of queries we are continually receiving from soldiers and sailors with respect to permits to use their motor cycles or cars when on leave, we repeat that the special motor spirit licences issued to officers and men home on short leave from the Front will be granted only to the registered owners of motor vehicles or to those who have a near relative, such as a father, mother, brother, or sister who is a registered owner. When applying for one of these short leave licences the applicant must state the registration number of the car on which the fuel will be employed.

new gas permits are to be issued ex pt "for public utility services operatin north of the southern boundary of D ham and Westmorland." The exact in rpretation to be put on the words " blic utility services" remains to be se .

Pe ol Restrictions.

eaking at a recent meeting of motor cy ists, Mr. A. W. Torkington, of the A.U., mentioned that Sir Boverton R wood, of the Petrol Executive, had ir rred that after the end of April it w probable that the petrol restrictions w ld be relaxed a little.

M ourne to Sydney Record.

is record has recently been broken b Fred Berry, driving a Harley-Davidson si car outfit (carrying spares and military d patches but apparently no passenger). E time was 22 hours 20 minutes, the p vious record time being 23 hours 40 m utes by a solo machine. The distance is 66 miles.

A Raids and Brilliantly Lighted Cars.

lention was made in these pages of a eport concerning a brilliantly lighted c , often followed by an equally brilli tly lighted motor cycle and sidecar, s n careering through the streets of S en and Richmond during air raids. A the time this paragraph was written w were fairly confident that the vehicles r erred to were on urgent duty, but t s fact has been confirmed by an F.C. officer living in the locality, who a ures us that the two vehicles in q estion are engaged on important work c nnected with raids for which adequate l hts are indispensable.

Motor Cycling in Holland.

The Dutch Army has many motor cycles, including Douglas (English), Excelsior (U.S.A.), Eysink (Dutch), Harley-Davidson (U.S.A.), and Simplex (Dutch).

Fords and Motor Cycles.

The fact that the price of Ford cars has been advanced is hailed with joy by American motor cycle dealers. Tin Lizzie has always been a rival to the single-tracker over there.

Identification Cards.

Munition workers granted petrol permits to allow them to get to their work will be provided with identification cards authorising them to use their petrol between given points.

Lubricating Oils.

Every man in workshop and garage who economises lubricating oils and greases is helping his country. He should, however, take care not to overdo it.

Dual Spark.

A plug which gives two distinct sparks is the latest accessory. Each spark is independent of the other. Useful for back cylinders of oil-cooled twins.

Looping the Loop.

Airmen were not the first to loop the loop. A stage motor cyclist did this stunt twice nightly, years before Pegoud accomplished his startling feat.

What's in a Name?

"Hoyt to assist Sec. Rinck" is the headline in an American motor cycle paper.

Help!

A hood and screen is the latest gadget on a motor cycle. The crossing of Salisbury Plain in a gale during a London-Exeter trial will now lose its terror (!).

Twin and Single.

It is when passing through congested traffic that one appreciates the large reserve of power provided by the big twin, but the single always will be popular while the fuel hill retains its present importance.

Sidecars in Holland.

We understand sidecars are not very popular in Holland.

Motor Light Cavalry.

We may yet have motor cycle light cavalry. In Africa the motor mounted infantry did excellent work.

Chance for Inventors?

Camouflage experts have not yet invented a way to make petrol-less motor cycles look like push-cycles.

S.P.C.M.C. Wanted.

Recently we saw a medium-powered twin outfit with six adults up. A case for the Society for the Prevention of Cruelty to Motor Cycles.

Motor Cycling in Ireland.

The Irish Cyclist and Motor Cyclist reports that roadside repairs were a feature of St. Patrick's Bank Holiday. Repairs to what? Do they still motor cycle on holidays in Ireland?

Petrol after the War.

The Petrol Economy Officer recently stated it was probable, after the war, that everyone requiring petrol will be called upon to show good cause why he should be permitted to use it.

The Military Motor Cycle.

The war has proved the value of the motor cycle, but old motor cyclists, with visions of the Army type push-cycle in mind, groan when they think of a Mark ? military motor cycle.

Hot Air Turbine.

We remember a hot-air turbine, supposed to have been invented by a Coventry man, being exploited by a company promoter in Canada. Now is the time to prove the merits of the invention. Would the Government allow us to use air without restrictions?

A Bijou Side Delivery Car.

A Western American trader has built a light side delivery car for his Indian flat twin. This engine is smaller than any twin in this country, but then Autowheels are harnessed to runabouts in the States.

Despatch riders who had an exciting time during the Cambrai offensive, but came through unscathed. Reading from left to right: Cpls. A. W. Byers, A. K. Byers, Cyril Mercer, and F. J. Palmer. The machines are Douglases and a Triumph.

COMFORT IN SIDECARS.

A Suggestive Criticism of Prevailing Practice in Sidecar Body Construction.

A pre-war model sidecar on the road. This photograph illustrates several of the points mentioned in the accompanying article, including lack of weather protection and convenient accommodation for the passenger's arms.

ALTHOUGH sidecars have long been the most popular means for the motor cyclist to carry an extra passenger, and no casual criticism will injure their prospects for the future, no one has yet suggested that there is no room for much further improvement both in chassis and body design. Chassis design suffers, if anything, from over discussion, and the liveliness of interest in the subject has been frequently emphasised by the pages of *The Motor Cycle*. Bodies, however, seem to suffer from the attention paid to chassis, and as a result such progress as they have made seems to be more of an accidental than a deliberate nature.

There are three main points that make or mar a sidecar body, or rather, perhaps, three items under the one main point of *size*. These three items may be regarded as (1) width, (2) length, and (3) depth, but before we can consider any of them we must ponder over the ultimate end to which these are but means.

Riding Position.

Before we can decide upon the essentials of a sidecar that will give an ideal riding position we must know what that position is and what individual factors go to its determination. These factors are three in number, and consist of two angles and what may be most simply described perhaps as a support.

The first of these two angles is that between the back and thighs, and is, of course, determined by the angle made between the back of the sidecar upholstery and the seat, while the second is that between the thighs and the remainder of the leg, being determined by the angle at which the sidecar seat is tilted and the height of the seat above the floor, as well as the length of the whole body of the sidecar. The "support" is really another angle, but the angle aspect is less obvious than it is in the other two cases. I refer to the angle of the neck that follows as a consequence of the shape of the sidecar back, and depends on the presence or absence of a support for the head of the passenger when he is sitting in the position tha follows naturally from th general construction of th sidecar.

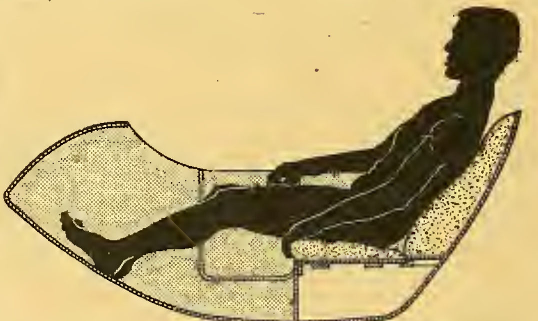

Fig. 1.—The lounge type of sidecar, very comfortable except for the passenger's neck. The passenger must either look at the sky all the time or risk a severe stiff neck.

Accommodation for the Arms.

There are, of course, othe items to be considered whic are of some importance. Fo instance, the accommodatio provided for the arms is point that often receives onl very casual attention in to many sidecars. Certainl passengers differ in thei tastes, and, while som would prefer to have thei arms hanging over the sid of the car, others like t have their arms comfortabl ensconced at their sides— please note that I sai comfortably ensconced, n jammed in as if in imitation of the proverbial sardin

Size of the Body.

All of which requirements lead us logically to o important item—the question of the size of the bod Ignoring freak designs intended to stow away ma passengers, I can honestly say that I have seen ve few really roomy sidecar bodies that have made th appearance on the open market. The type to whi I refer is shown in fig. 1, and it will be seen th not only does this design provide plenty of leg roo but it also allows the lazy passenger to let his a go wherever they will. He may ride with his a comfortably along each gunwale, fold them, or may keep them out of sight and out of the cold so where in the region of his waist. And above all and this is my point—in all these evolutions he ne loses his dignity nor appears to be aping an acrob A Birmingham firm has achieved these ideals a sidecar that gives a more or less recumbent posit —and a very comfortable position at that.

Width of the Sidecar Body.

The first item in the matter of size of the b is that of width—the main detail in the passeng comfort for which it is resp sible being the disposal of arms. I have already d with this, so will say no m other than to summarise matter as follows: The b should be of sufficient widt allow the arms of the passe to come comfortably in should he so desire it—as certainly will in bad weat A body that will allow of will automatically allow c certain amount of mover and will prevent that wedge

Comfort in Sidecars.—

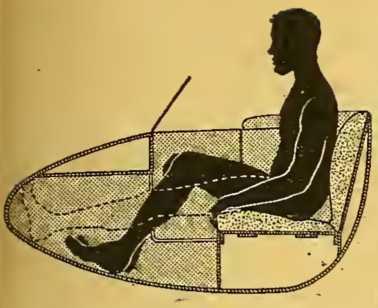

Fig. 2.—The type now fortunately almost obsolete, about which the less said the better. Note the strained angle of the passenger's back and legs, and the very efficient "shin barker." Also the equally uncomfortable alternative position shown in dotted line.

sensation that comes from riding in the majority of sidecars on the road at the present time. I have noticed, however, that where a sidecar concern is responsible for both body and chassis, the general result is in every way superior to the efforts of smaller firms who are body makers who buy chassis or chassis makers who buy bodies.

Length of Body.

Much, of course, depends on the length of the passenger, and as a body cannot very well be made of variable length a compromise is necessary. However, in fig. 3 the body is longer than normal, and adjustable footrests are provided. Who has not felt the lack of some support for the feet when on a long journey in a sidecar, especially if the roads are a trifle on the bad side, so that some pressure may be maintained without effort against the padded back?

The length of the seat depends on that of the body as a whole, and it also plays its part in determining the angle at which the legs will naturally lie. Hence I shall refer again to this point when dealing with the angles already mentioned as providing the keynote of sidecar comfort.

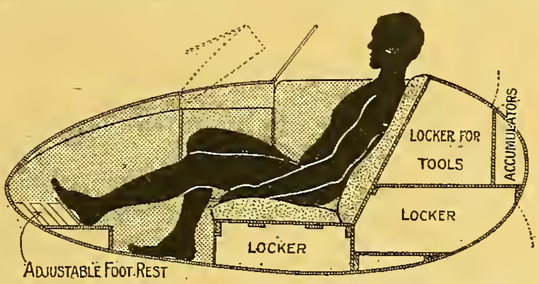

Fig. 3.—A suggested design embodying the ideals spoken of in the accompanying article. The main features are comfortable riding position, adjustable footrests (after the same lines as the adjustable footboards in a rowing boat), and ample weather protection.

Depth of the Body.

Depth is perhaps the point on which most divergence of opinion exists. Some passengers like to feel themselves *on* the vehicle that is carrying them, while others prefer to be in it. Personally, I am all for the latter, though I cannot say I am in entire agreement with carrying the practice to such lengths as Mr. Pemberton Billing has done in his car (illustrated in *The Autocar* of October 6th, 1917). Nevertheless, both the designs shown in figs. 3 and 4 ensure that the passenger is well protected, while that in fig. 4 does not prevent a normal-sized passenger from travelling with both arms resting on the gunwale if he so desires.

One part of the body in which the question of depth is often overlooked, though it is of vital importance at this point, is at the beginning of the fore-deck, at the point level with the hinge of the door. My shins still show the marks of wounds received while travelling (before November 1st last) in a late 1917 model. The cross-sectional views of the two suggested designs (figs. 3 and 4) at this point will show that my wounds have taught me something. No ordinary passenger would bark his or her shins in getting into either of these 'buses, no matter how great the hurry.

The Angles.

And now for these angles. Let me say at once that I have no intention of stating definitely what they should measure. This is impossible if passengers insist on varying in size, and in the absence of any evidence to the contrary we must assume that they will. However, the illustrations emphasise the importance of these angles, and also give some idea of what they should measure when the passenger is an average-sized human being. As regards the "neck angle," notice that the support at this point in figs. 3 and 4 is quite different from that in fig. 1.

Of course, the most important angle of all is not one of these already mentioned, but is that made by the back of the sidecar (inside, of course) with the horizontal. Taking a straight line from the top to the bottom of the back—the upholstery itself will not be a straight line—this should generally give an angle of about 80° with the horizontal. The angle between the floor and the back is not of great importance, although it might appear to be so at first sight. The position of the passengers' legs and the angle at which they rest depends, as already shown, more on the position of the seat than on anything else, and the angle between floor and back has most influence on the appearance of the sidecar.

The provision of a false floor is a minor detail that may be retained or dispensed with according to individual tastes. If retained it would make a useful locker.

While not such a fundamental matter in the actual construction of a sidecar the upholstery has a large part to play in deciding the passenger's comfort—or lack of it. There are the two painful extremes, one

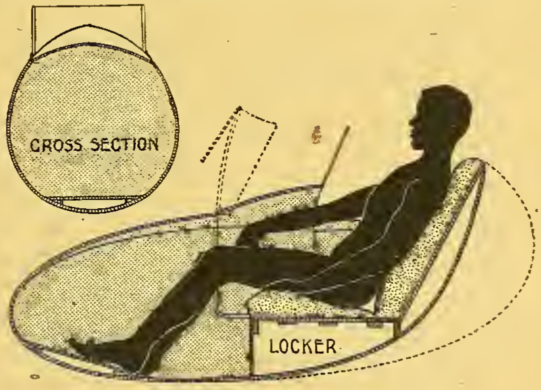

Fig. 4.—The weather protection in this design is made less prominent than in fig. 3, but it is well looked after. This body could be very easily streamlined by the addition of a bulbous back as shown by the dotted lines. (Inset) A cross sectional view of the two designs shown in figs. 3 and 4. It will be seen that there is plenty of room for the passenger's knees in all likely positions.

Comfort in Sidecars.—

of which bulges out into the small of the passenger's back but gives no support to any other part of it, and there is the other extreme that meets his shoulders but ignores the presence of any other part of his back which is consequently unsupported. Of the two the first is certainly the worst, but the other is most unpleasant when it has to be endured for anything like a long distance without a break.

The upholstery should have a gentle curve to meet the small of the back and another to come somewhere in the neighbourhood of the shoulder blades or neck, the most perfect example of this work that I have yet seen being in the Palladium car, to ride in which is a real treat.

The Suggested Designs.

And now a word as to the suggested designs. Of course, they are open to criticism, and criticism will be welcomed, but they do, I think, obviate some of the most glaring defects I have mentioned. As regards their general outlines, though this is made streamline to satisfy the modern critical eye, they are not intended as essentially speed designs.

One of the most desirable of all points—the protection of the knees—is amply provided for by the provision of a lid, hinged near the door, which opens and closes upwardly while the door is being used. This lid is a very valuable asset, and I can never understand why it is not more frequently fitted to sidecars, as the addition can be very easily carried out. Screens and hoods are quite minor details.

As regards the size and weight of the two bodies illustrated, that shown in fig. 3 would be somewhat above the normal, of course, but the other may be quite easily kept within reasonable limits, and an aluminium body of this type might be even lighter than the ordinary type built of more common material. But, of course, that would mean expense which is another question, depending not so much, perhaps, on the driver's taste as on the identity of the passenger.

RAMA.

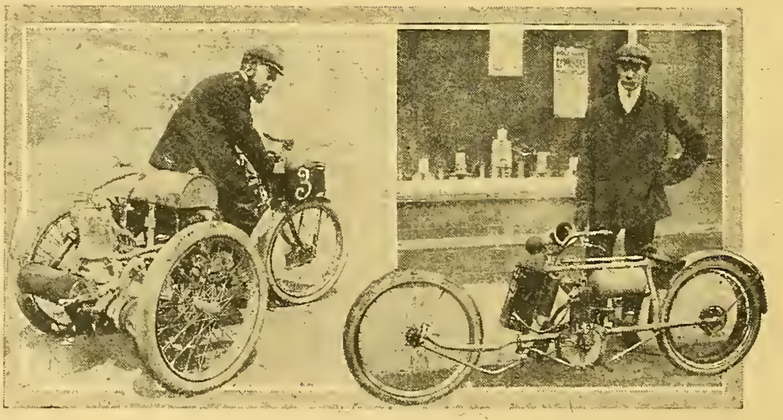
Circumventing the Security Bolt.

Why and How Ordinary Security Bolts may be Discarded.

SECURITY bolts are often a cause of endless trouble, and in these days when tubes are generally fitted complete with a valve security, bolts are quite unnecessary. If the rim be drilled to take them, however, provision must be made to prevent water entering through the holes when they are removed, otherwise the outer covers will soon become rotted round the tread, and tyre troubles are certain to ensue. Here are a few hints for the rider who has decided to remove his security bolts and trust solely to the valve security—a very wise decision.

The simplest plan for keeping water out of the bolt holes is to make three or four turns inside the rim with insulation tape, drawing the tape up as tightly as possible, and seeing that it securely covers the bolt holes. This lining of insulation tape effectively prevents a cover creeping, quite independently of the valve security, and when the cover is ultimately removed it will be found that the bead is firmly stuck to the tape. The Leosco tube protectors answer the same purpose, but are probably difficult to obtain at the present time. It may be added that this insulation tape tip is a good one to carry into practice if trouble is experienced through a slack cover creeping.



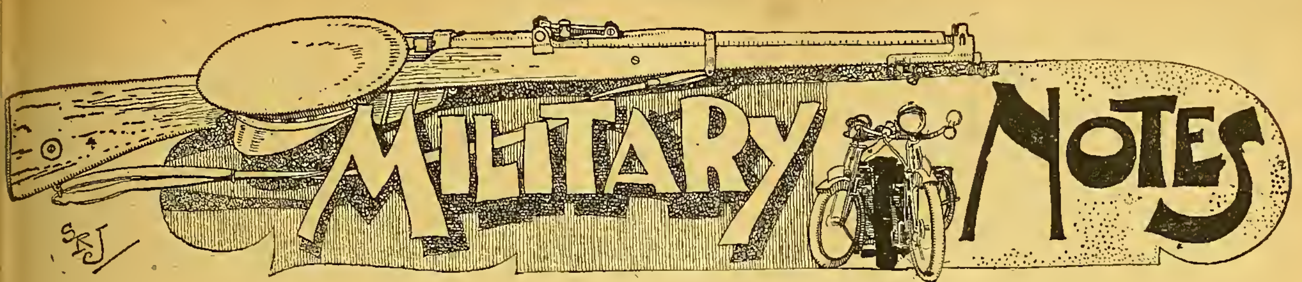
CURIOSITIES IN MOTOR CYCLE DESIGN.

(Left) A motor tricycle used about fifteen years ago as a pacing machine for track cyclists. (Right) This motor cycle was seen running on the road in 1909. The frame structure will strike many as novel, although a somewhat similar design of machine was produced by the James Cycle Co. in 1908.

Perhaps the most effective way, though the most troublesome one, of preventing water entering through the security bolt holes is to solder a small piece of tin over each hole, but a simple and equally effective method is to utilise the original bolt. Place the bolt with its rubber protector downwards on the floor, and hit the end of the bolt a smart tap with a hammer. This will cause the central pin, complete with its head, to fall through the plate carrying the rubber protector, and, by separating the two, one is then in possession of the centre pin. This should be placed in the hole it is to occupy, and hammered smartly a few times to cause it to make a seating for itself in the rim. It is then fixed in position and drawn up tightly on the water-excluding leather washer, after which the outer cover is replaced. Should the head of the bolt be found to protrude inside the rim much further than the heads of the spokes, it should be filed down.

It may be added that if it is found on removing a cover that water has entered through the security bolt holes, something should be done at once to prevent it, and the cover thoroughly dried before replacing.

CHINOOK.



The Full Stop to a Sore Point. How a D.C.M. was Won.

THE ARMY BILL.

THE Army (Annual) Bill provides for five million men, excluding those in India.

* * *

CIVIL EMPLOYMENT FOR OFFICERS.

A SPECIAL department is being inaugurated by the Ministry of Labour to find civil employment for officers on relinquishing their commissions.

* * *

BILLETING THE W.A.A.C.'s.

WHEN the necessary accommodation cannot otherwise be obtained, the Army (Annual) Bill grants the power to billet women enrolled in any of the auxiliary corps. This applies to the W.A.A.C.'s, the Wrens, and other women's units.

* * *

DISCHARGED MEN.

DR. ADDISON (Minister of Reconstruction) states that arrangements have been made with a large number of trade unions and employers' organisations, whereby discharged and demobilised men will be specially trained for certain industries, such as engineering, aircraft, and the leather and furniture trades.

FAMILIAR NAMES.

WE recently had a visit from J. Oliphant, who before the war was well known as the rider of a Premier. He is still attached to an M.T. depot in the Metropolitan area, where he is serving as a tester.

He recently came across Sidney Garrett, who is now a lieutenant in the R.F.C., and stationed at an aerodrome some distance from town. Garrett, who recently obtained his wings, used to ride a Regal-Green.

Oliphant also lately saw F. Guiver, who is now in the Aeronautical Inspection Department.

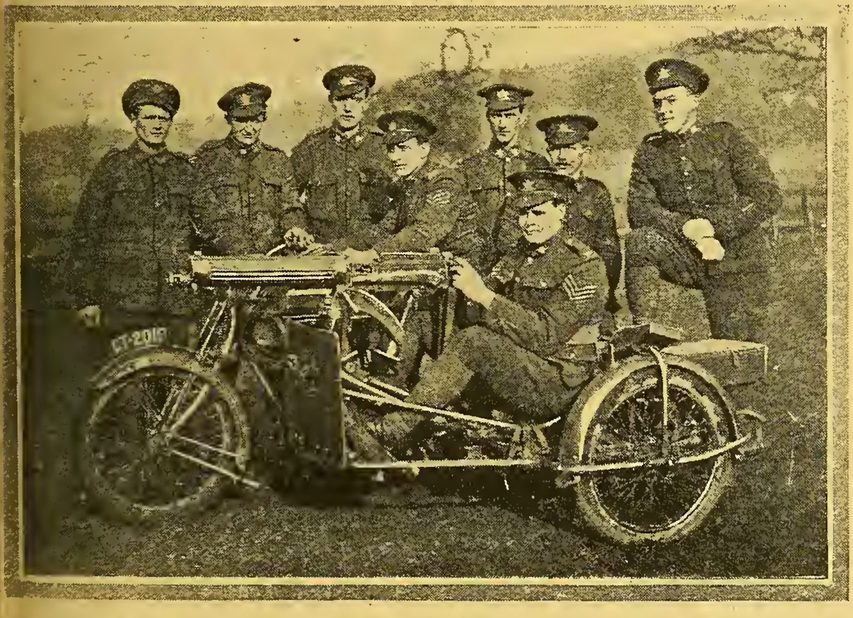
LETTERS ON THE "CUSHY JOB" QUESTION.

A GREAT deal of correspondence has reached us on the subject of the A.S.C., M.T., and the danger encountered in carrying out work with that corps. It is quite impossible to publish the letters; and even if portions only were extracted, it would be weeks before we could utilise those already received. The subject seems to be an everlasting bone of contention; and as nothing can be gained by a resuscitation of a subject which was thoroughly discussed some months ago, we have decided to terminate the correspondence and to publish no more letters on this matter.



N.C.O.'s and men of the first Canadian Motor Machine Gun Brigade undergoing a Clyno course at a M.M.G.S. depot.

MENTIONED IN DESPATCHES.

THE names of the following officers, who are well known in the motor cycle world, have been brought to the notice of the Secretary of State for War for valuable services rendered in connection with the war:

Temporary Major F. H. Bale, A.S.C. Major Bale is the son of the London manager of the Swift Motor Co., and was closely associated with Swift motor bicycles prior to the war.

Temporary Second-Lieutenant E. W. Walford, R.F.C., Special Reserve.

WINNING THE D.C.M.

ARTIFICER-CPL. A. MACKINNON, D.C.M., sends a few interesting details of his exploit which earned him the D.C.M. His disregard of danger, the *London Gazette* said, enabled valuable information to be delivered at a time when all other means of communication had been interrupted.

Cpl. Mackinnon says: "I thought perhaps my little experience with a W.D. Triumph might be of interest to you. I was in the Dunkirk affair, and, as the papers told you at the time, we had rather a hot time of it. I managed eight trips through Fritz's barrage, and it was some barrage to put up. Motor cycles were for the time the only means of communication, the shells destroying other means as fast as they were put down; such conditions make me appreciate the reliability of this mount. I had no trouble whatever until my eighth journey, when I 'clicked.' An H.E. got me well in line, and when I gathered myself together and eventually found my bicycle, which was in the opposite ditch to myself—it was as black as your hat at the time, and I dare not strike a light—you can guess there was a small percentage of 'wind up,' but—would you believe it?—it started on the first kick, which was luck indeed, for I do not believe I had another kick in me. Anyhow, off we went, both a bit wobbly, but with six miles in front of us. How I arrived there I do not know; things were a bit too 'flurry.' I better remember finding myself in hospital with a decent bit of the shell case finding a home in my thigh.

"After that, I was told, I had to be lifted from the machine, which was covered with gore—my own particular speciality. The trusty old mount had been hit in no fewer than seven places, one hit cracking the cylinder. However, here I am ready again for the next issue. The experience has made me the possessor of the D.C.M., the ribbon of which blends well with the Mons ribbon."

LETTERS to the EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

PRESSURE IN A TWO-STROKE CYLINDER.

Sir,—I shall be glad if any of the readers of *The Motor Cycle* could inform me of the conditions obtaining during the exhausting period in a two-stroke cylinder. A diagram in Dr. A. M. Low's admirable little book, "The Two-stroke Engine," shows the minimum pressure in the cylinder equal to the pressure of the atmosphere, but I have recollections of seeing it stated that the pressure at the end of the stroke is less than atmospheric pressure, due to the kinetic energy of the exhaust gases.

CHAS. ROBERTSON.

A PLEA FOR BETTER STANDS.

Sir,—I was greatly interested in the article appearing in your paper anent the above, and would like to say that I am in full agreement with your contributor's remarks *re* the inefficiency of present-day encumbrances, misnamed stands. But in my opinion the trouble will only be surmounted by a stand made of U section *pressed steel*, after the style of those fitted to Harley-Davidson machines. Why make stands with brazed members when those made of pressed steel are cheaper to make and stronger? The same may be said of carriers. These have an unhappy knack of fracturing near the lugs. They could be produced in *one piece* by making them also of pressed steel, quite easily accomplished and far more workmanlike.

L. V. MERLIN.

LADY MOTOR CYCLISTS IN THE BRITISH ARMY.

Sir,—One of the most vexing questions of the day is the man-power problem. Appeals are constantly being made for skilled men to serve in H.M. Forces, especially in the R.F.C. or the R.N.A.S. Whether the man-power of the country is used wisely or to the best advantage is a very debatable question.

In *The Motor Cycle* of March 14th, on the subject of women transport work in the R.F.C., you state that, although the women do their own running repairs, etc., the mud on their motor cycles is removed by mechanics. Surely, as the man-power question is so pressing, a mechanic can be put to better use! I understand these women are supposed to take the place of a man: then surely they ought to do a man's work, otherwise their employment is waste of time and money.

MECHANIC.

Hamble.

A POST-WAR IDEAL.

Sir,—I should like to say a few words about "A Post-war Ideal," mentioned by Mr. J. A. Jeapez in the issue of March 21st.

A large two-stroke would be quite satisfactory if designed correctly. For evidence of this, see the American Schickle 6 h.p. two-stroke single-cylinder, one of the most popular machines in the States, but vastly different from the poor specimens of indifferently lubricated, and often carelessly designed, engines, which, with a few notable exceptions, make up the horrid little spluttering "tup-tup-tup—trrrrr—hissss" 'buses to be heard and smelt in this country. Radco spring forks, however, can hardly be heavy enough for such a machine, and their design does not lend itself to a thing of beauty in the way of outline. Has Mr. Jeapez seen the new Mark II. Druid or the latest Yankee Reading Standard spring forks? He will like them both, I am certain, and, to my mind, the new Druid is perfection.

The general design of a machine such as the writer outlined in his letter would be very nice, and I think that he knows just about what a comfortable, handy, and speedy 'bus ought to look like, and I really cannot imagine a more delightful design, only that he might add a Schebler carburetter and twist grip controls to attain that height of perfection known at the Grahame White Flying School as "Simply I-T, old thing! what?"

Derby.

GEE WHIZZ BANG.

Sir,—I am pleased to see that Mr. Jeapez is looking for the same engine as I am—namely, a simple, economical, big-single two-stroke.

I believe the troubles of four-stroke single-cylinder combinations are due to uneven torque, which would be sufficiently improved by doubling the impulses. A flat twin four-stroke will do this, and give good engine balance as well, but it is a very expensive alternative to the two-stroke single in first cost.

"Chinook" has said, "Smooth torque does not matter, but good balance is all important." "A Tilter at Windmills," in March 21st issue, says exactly the opposite. I back the latter. What say others?

W. R. DEUCHAR (2nd-Lt., R.E.).

MAKING GAS CARBURETTER AND HOLDER.

Sir,—I am sending sketches of a conversion to an Amac carburetter, which I carried out myself in January of this year. The main body was made out of a solid bar of steel, but it would be easier to make it out of an old lubricator about 4in. in diameter. The cap was turned from the same bar, and has $\frac{3}{8}$in. holes drilled round it, about eight (see fig. 1). The plate is made a little larger than the cap, so that you can grip it to turn it. The gas is taken through a $\frac{1}{2}$in. gas pipe, which is tapered as shown. At first I tried a $\frac{1}{4}$in. pipe, but the engine would hardly keep the machine moving at full throttle.

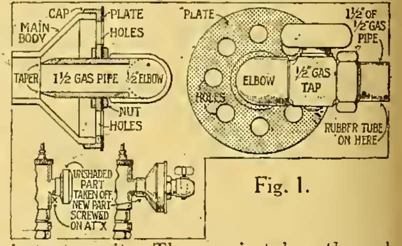

Fig. 1.

The conversion was carried out on a $2\frac{1}{2}$ h.p. Calthorpe two-stroke. It might be advisable to mention that a big pipe with the tap half on is better than a small pipe with the tap full on. The controls are worked in the usual way as with petrol, the fitting being screwed to the air intake. The bag (see fig. 2) is carried on the carrier as shown, and is 4ft. × 3ft. × 3ft. It is not inconvenient except on muddy roads. *All* the fittings are home-made, the bag being made of thin waterproof sheeting and machined together with double seams. The whole outfit cost about £1, and will take one for about eight miles on one half charge, as the bag is rather cumbersome when quite full.

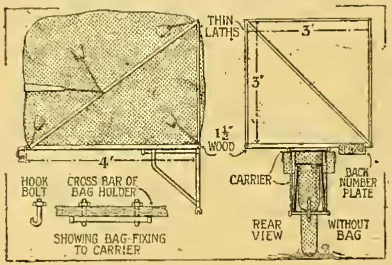

Fig. 2.

E. A. REYNOLDS.

AN IMPROVED TOOLBOX.

Sir,—In your issue of March 21st, page 270, I note the registered design of toolbox and number-plate over the initials of "W.H.B. (Dudley)."

This design, I should like to point out, was registered by myself in 1908, and is at the present time in use. This design of toolbox and number-plate was used by me in the April and July (1909) Quarterly Trials.

I should at any time, as a manufacturer, be pleased to make any arrangements with "W.H.B." regarding this fitment which would no doubt be to our mutual advantage.

A. H. HADEN.

SIMPLE TYPE CARBURETTERS.

Sir,—With regard to the suggestion in *The Motor Cycle* of March 14th for a floatless carburetter, it may interest your readers to know that I experimented with a similar arrangement about twelve months ago. I cut off the choke tube of my Triumph carburetter with a hacksaw, and sweated a piece of copper tube of the same external diameter in its place. To this I fitted an arrangement almost identical with that suggested by "Chinook," but found that the disc was much too large, so I gradually cut it down to about half the size, and arranged for the petrol to spray *above* the disc, which, to my mind, is a much better idea. I found the extra air very necessary, especially at speed, but the lever had to be very delicately handled. The consumption was improved from 80 m.p.g. to an average of 112 m.p.g. over several hundred miles. I was exceedingly pleased with this device even in its crude state, but was unable to complete my experiments, having been refused any further petrol. For slow running, fast work on the level, and hill-climbing, I found it an improvement on all the ordinary carburetters I had previously used. My machine is a two-speed Triumph. S. L. BURNARD.

Sir,—I have read with interest "Chinook's" article on the "Machine for the Multitude," especially his somewhat patronising admission that the two-stroke is capable of real service.

Although most excellent results are obtainable with a simple form of chain drive two-speed gear such as the Enfield, I feel sure that if this were incorporated with a further choice of two ratios in the final drive to the back wheel, not only would production costs be kept at a minimum, but the overall efficiency of the transmission would be higher than if a gear box were interposed.

"Chinook's" suggestion for a carburetter was anticipated in the "Roubeau" carburetter of about the year 1899 or 1900, which was almost identical in construction, but had an additional collar fitted for regulating the area of the air intake. No device for flooding was fitted or found necessary. This carburetter was made of the well-known Cothias metal, and sold at about 18s. I believe it was the first carburetter to be offered for sale as a separate unit.

In view of the efficiency of the modern Amac or Senspray carburetter, any retrograde step is to be deplored, especially as the saving per machine is only a matter of shillings.

I cannot agree with "Chinook" that the two-stroke is in any way an "affliction," and he himself acknowledges its wonderful capacity for withstanding abuse of every description, including full throttle running for a time, which would absolutely dry up the four-stroke under similar conditions.

The bane of the two-stroke has been the "petroil" system of lubrication, again an effort in the direction of cheapness. Given a rational oil feed to the vital parts as is employed in a two-stroke of almost household repute, not only is oil consumption reduced to a minimum, but wear of bearings is almost unknown.

I cannot but feel, from the tone of his article, that "Chinook's" experiences of an up-to-date two-stroke are somewhat limited, or he would not have indulged in such sweeping criticism.

The buying public is by no means devoid of appreciation for a sound article, and I venture to think that price will never be the sole deciding factor *apart* from quality.

B.E.F. LT., R.F.C.

ACCUMULATOR CHARGING.

Sir,—Referring to my article on "10,000 Miles with a Dynamo Lighting Set" in the issue of March 21st, I should be glad if you would publish the following correction. The paragraph towards the end of column 2 thus: "This was continued until the voltage per cell reached the value of, roughly, 2.2 volts . . . " should have read thus: "This was continued until the *charging* voltage per cell reached the value of 2.7 volts . . . ."

As published the sentence is vague, and it may lead your readers to a wrong impression regarding the accuracy of the tests.

Needless to say, in comparative tests such as the article dealt with, it is essential that identical conditions obtain during each test, so far as it is possible to repeat them, otherwise errors of measurement may completely mask the changes that are being looked for.

For this reason the charging of the cells before each test was continued until a perfectly definite condition of the electrical circuit was reached, as is indicated by the corrected sentence. This condition could be repeated as often as required. A.K.

Teddington.

ANOTHER LIGHTING PROBLEM.

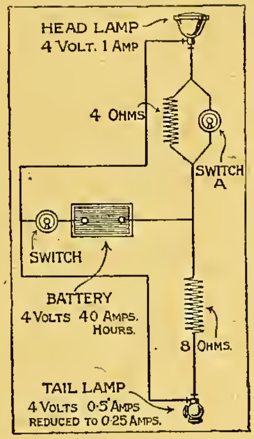
Sir,—Herewith is still another diagram of a wiring arrangement for a solo mount, which I hope Mr. Percy and others will find useful.

(1.) No arrangement of wiring will allow lamps of widely varying current consumption to be connected in series. The proper way to tackle the job is to place resistance wire in the circuits leading to the lamps. For the tail lamp four and a half yards of Eureka or platinoid wire, No. 24 s.w.g., will be required, which will give about 8 ohms resistance, and will reduce the current to 0.25 amp.

The head lamp will require four yards of Eureka wire, No. 22 s.w.g., placed in parallel with the wire to the head lamp, which will give a reduction of 50% with the resistance wire in use.

With the switch A closed, practically all the current passes through the copper conductor. With the switch open, the current is shunted through the resistance wire before reaching the head lamp.

It will be understood that the resistance wire should not be spread out in the way shown in the diagram, but should be wound round a piece of wood, with a small space between each turn.



If insulated wire can be obtained, it could be wound on a small bobbin, and would occupy a very small space indeed.

(2 and 3.) A 12 c.p. lamp would require a large battery, or else frequent charging would be the only alternative. A 4 volt 40 amp.-hour accumulator would be quite satisfactory. With a 4 volt 1.0 amp. bulb in the head lamp and a 4 volt 0.5 amp. (reduced to 0.25 amp.) bulb in the tail lamp, the battery would last for about thirty hours at one charge.

(4.) Any voltage where volts × ampères = 12.

(5.) A metal filament lamp (usually made of tungsten or osmium). A. A. MORRISON.

A CONVERTED SCOTT.

Sir,—Would Mr. L. S. Parker kindly say if his converted Scott has been used with a standard sidecar? If so, to what portion of the frame does he fit his upper after coupling; and are the results satisfactory when used as a combination?

The design is very interesting to a pre-war Scott rider, and I only wish that I had a Scott standard or converted (less the rotary valves) out here in Macedonia. At present I daily ride over a track, for the gradient and conditions of which, especially after rain, a Scott would be ideal.

Some weeks ago the roads were a foot deep in snow, and, until cars had made tracks, our belt-driven machines would not move through it. A chain-driven machine without mudguards would have filled the bill.

Of the two types of machines out here, the Triumph stands the work very well. But, apart from standardisation for replacements, etc., it is very far from the most suitable make that could have been chosen. The magneto is very much in the worst position; and after some time soon shows how non-waterproof it is, irrespective of its make.

The usual faults—soft rims and insufficient clearance (mudguard and crank case)—also advertise their presence. However, I do not think that there is any American machine on the European market which would stand the continuous gruelling to which ours are subjected, and remain in the condition and readiness for work that the Triumph does, with all parts and fittings complete.

Macedonia. G. H. DURSTON (D.R., R.E. Signals).

PISTON DESIGN IN TWO-STROKES.

Sir,—With reference to Mr. D. J. McDougall's letter in your issue of February 7th on the subject of piston two-stokes, I shall be greatly obliged if he will inform me in what way the inertia of the exhaust gases passing out of the exhaust port causes a partial vacuum in the cylinder.

A two-stroke piston with a badly-designed deflector actually traps part of the exhaust charge, because of the reluctance of the exhaust gases to leave the cylinder after the exhaust pressure has fallen below the compression in the crank case.

If a partial vacuum existed at the end of every exhaust stroke it is quite obvious that we should have a fairly well-scavenged engine, but well-scavenged engines have resulted more from attention to the design of deflectors in conjunction with certain crank case pressures than by any vacuum effects produced by the exhaust gas. J.D.

Birmingham.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—We motor cyclists attached to the R.F.C. would be glad if we can, through the medium of your paper, ventilate our dissatisfaction at being classed as *non-technical* under the new R.A.F. We feel that, as we do all overhauls and running repairs ourselves, we should be put on the same footing as M.T. drivers, who have proper fitters, etc., to do their overhauls. We feel sure you will agree with us that we should be classed as technical men and get the higher rates of pay and promotions.

AIR MECHANICS.

Sir,—*Re* the mustering of motor cyclists under the non-technical branch of the new Air Force, I really think an injustice has been done to us to grade us in that way, when M.T. drivers are included under the technical branch. The majority of us cyclists do all our own repairs and complete overhauls, whereas a M.T. driver generally has a fitter to do his. The least the authorities could have done would be to classify us D.R.'s instead of privates, considering the rough job we have, as it is very rarely that we get any time off. Also why should we not have some distinctive badge to wear, the same as other motor cyclists in other corps? I am sure, if so influential a journal as yours would put it forward, it would be taken up. This is the view of practically all the cyclists in the corps to whom I have spoken. We do not wish to grouse, but would appreciate a little appreciation. OLD READER.

Retford.

THE SINGLE V. THE FLAT TWIN.

Sir,—I have been very much interested in the discussion in the correspondence columns of *The Motor Cycle* on the relative merits of the 2¾ h.p. flat twin and the 4 h.p. single for despatch riding Overseas.

After a personal experience of both types during almost three years of active service in more than one country Overseas, I consider the 2¾ h.p. flat twin *the* machine.

I rode a 2¾ h.p. in the early part of the war, and it was an absolutely no-trouble mount. Later I had a 4 h.p. single, and then began to experience the delights of handlebars snapping off, mudguards and carrier breaking (although the only thing the latter carried was a spare belt).

Now I ride a 2¾ h.p. flat twin again, and am quite satisfied. The tools remain packed away in the tool bags. The hubs do not fill up with liquid mud and then seize solid. The machine may stand out without cover in hail, rain, or snow, and still start up by pulling over the back wheel a quarter turn. I have fitted Terry's spring links to the front forks: these are a great improvement for the "roads" out here. It is a wonderful little engine, and its even torque does not try one's nerves as a thumping single does. One can appreciate a lightweight after one, wearing a gas helmet, has ridden with a weighty single into a shell hole in the road.

I might say that I am over twelve stone in weight, and as I am attached to a field ambulance this sort of work is a severe test for any machine, as the roads are indescribable after an advance. The only improvement I could suggest for my little machine is a hand-controlled clutch.

Regarding inverted levers, I am very glad that my machine is not fitted with that type of lever, as I know from bitter experience how liable inverted levers are to catch any dangling chains or ropes when riding in the dense traffic of all descriptions here.

I may say that I am not connected with any motor cycle firm except as a potential *après la guerre* buyer of the 2¾ h.p. flat twin. H. HOPKINS, M.T., A.S.C.

FUEL LOSS AT CARBURETTER.

Sir,—I am indebted to a correspondent for drawing attention to an error in calculation of the velocity of the induced gases through the induction pipe. As far as the article itself is concerned this error does not interfere with the context, but for the benefit of those who have not made the necessary correction I give the following:

Let t = time taken to perform induction stroke in seconds

$$= \frac{60}{\text{R.P.M.} \times 2} = \frac{30}{\text{R.P.M.}} \text{ secs.}$$

v = volume of gas passing during induction stroke.

a = area cross section induction pipe in square inches.

V = velocity of gases through induction pipe.

We have then the condition that the gas travels $\frac{v}{a}$ inches in t seconds.

$$\therefore V = \frac{v}{a} \div \frac{30}{\text{R.P.M.}} \text{ inches per second.}$$

$$= \frac{v \times \text{R.P.M.}}{a \times 30} \text{ inches per second.}$$

$$= \frac{v \times \text{R.P.M.}}{a \times 360} \text{ feet per second.}$$

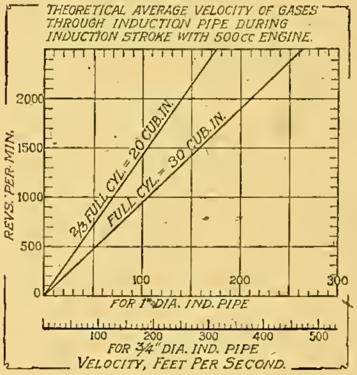
We have now a formula suitable for calculating the speed of induction gases for any volume, area, or r.p.m. figure.

In the example referred to we had $v = 20$ cubic inches, $a = .7854$, and R.P.M. = 1,200. Substituting these we have

$$\frac{20 \times 1{,}200}{.7854 \times 360} = 84.8 \text{ feet per second.}$$

This figure is approaching 60 m.p.h. Imagine a motor cyclist at this speed riding into a solid wall and you have some notion of what happens to the induction gases when the inlet valve closes.

To show the influence of r.p.m. and size of induction pipe on velocity of gases the curves shown have been plotted.



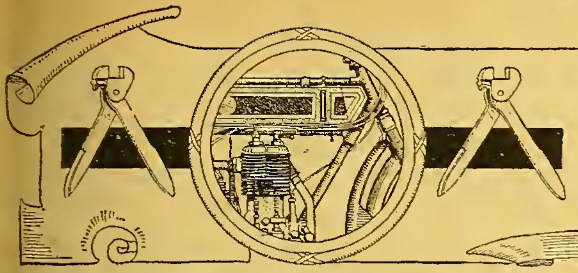
A leaflet published by Messrs. Prices' Co., Ltd., entitled "Miles per Gallon (Notes on Fuel and Oil Economy)" has been forwarded to me. In this it is shown that the theoretical value of the velocity of gases through an induction pipe of ¾in. internal diameter may rise to as high a figure as 200ft. per minute in the case of 500 c.c. engine running at 1,800 r.p.m.

A point of special interest is, to quote the leaflet, that "practical tests have shown that 10% to 15% improvement in consumption can generally be obtained by the simple expedient of converting plain jet holes into annular openings."

ENGRO.

SUMMARY OF CORRESPONDENCE.

The Palmer Tyre, Ltd., write us to the effect that they have received many applications for their "Map Books" and also orders for tyres (with cash enclosed), but no names and addresses given. Will those readers who have received no answer to their communication kindly write again?



TECHNICAL TERMS.

SOME REMARKS ON VARIOUS TERMS USED, AND OFTEN WRONGLY USED, BY MOTOR CYCLISTS.

The meaning of certain technical terms is far from being always correctly understood, and the following series of articles by "Rama" is intended to elucidate in simple language their individual meaning. It is assumed throughout the series that the reader is acquainted with the working of the motor cycle. Discussion on any interpretation of these terms which may be at variance with the usual ideas of our readers will be welcomed. (*The first article of this series appeared March 7th.*)

II.—THE VARIOUS KINDS OF EFFICIENCIES OTHER THAN THERMAL.

IN my last article I dealt with the term thermal efficiency, and explained how this was a factor very much depending on the compression ratio of the engine under observation. There are, however, other efficiencies in common use that, like thermal efficiency, are often wrongly described.

Mechanical Efficiency.

Mechanical efficiency is a term that is perhaps less often subjected to abuse than are most of its kind, but it may, all the same, pay for a little explanation. Briefly, the ratio of the amount of power put into any moving part to the amount that is given out is known as the mechanical efficiency of that part. Thus a certain pressure is exerted on the piston of any reciprocating engine during its power stroke, and that pressure should give out a certain power at the crankshaft—a power that may be easily measured and simply expressed in terms of horse-power. Now if the power actually given out is what calculation would lead one to expect, the mechanical efficiency of the engine would be described as perfect—in other words, of 100%.

When dealing with engines the consideration of this matter involves the use of two terms that in themselves help to explain the main term we are now considering. The first of these two subsidiary terms is *indicated horse-power*, and the second is *brake horse-power*.

Indicated Horse-power.

Indicated horse-power may be calculated from the following formula $\frac{PLAN}{33{,}000}$ in which P is the pressure per square inch on the piston through the whole working stroke (and is often described as the mean effective pressure and written m.e.p.) measured in lbs. per square inch; L is the length of the stroke in feet; A is the area of the piston in square inches; and N is *the number of power strokes* per minute (not the number of revolutions, notice). 33,000 is the number of foot pounds per minute that are taken as the equivalent of one horse-power—a point that will be dealt with more fully in a later article.

There is no need to enter into any full examination of this formula, but it may perhaps be well to point out that the product of P and A will give the total pressure on the piston throughout the firing stroke, and that in ordinary petrol engines at the present time the m.e.p. is generally in the neighbourhood of 80 lb. per square inch. We will assume that an engine has been calculated by means of this formula as likely to yield 5 h.p.—that is to say, that if it actually gave 5 h.p. its mechanical efficiency would be 100%.

Brake Horse-power.

But such an achievement is never realised, and another test is made to ascertain what power the engine actually does yield. This is the measurement of the brake horse-power, and is carried out by means of an instrument known as a dynamometer which records the actual power given off at the crankshaft, also in horse-power. Dynamometers have been frequently illustrated in *The Motor Cycle*, and so there is no need to describe the instrument now.

The dynamometer we will assume in the case of this particular engine gives a reading of 4½ h.p.—in other words, .9 of the indicated or calculated h.p. The engine would therefore be said to have a mechanical efficiency of 90%.

Another way of looking at this matter would be to regard the ½ h.p. lost as the power required to turn the engine itself. Thus an engine entirely free from friction would have a mechanical efficiency of 100%—an ideal that, according to all the accepted laws of motion, will ever remain unattainable.

Other parts of a car or motor cycle may be said to have a mechanical efficiency in just the same way. Thus a gear box requires a certain amount of power to drive it, so that while the drive from the engine to the gear box may be, say, of 5 h.p., the drive after it leaves the box may only be of 4.5 h.p. The box has thus absorbed .5 h.p., so that its efficiency is 90%, as it has absorbed 10% of the power supplied to it in passing that power along. Similarly, all parts of the transmission have this propensity for absorbing power, and the amount they absorb, or their mechanical loss, is of great importance when one is trying to get the very last ounce of power out of a machine.

The average efficiencies of the various popular types of transmission may be given approximately as follow:

Chain, 98%; belt, 85%; shaft, 90% (the shaft is lower than the chain as a result of the right-angled turns in the transmission system which it necessitates).

Technical Terms.—

Thus, it will be seen that the actual power that reaches the road wheels of a motor is very much less than that that should be available from the pressure that is exerted on the piston during the power stroke, and is also considerably less than that given out at the crankshaft. The average efficiency of a complete motor cycle chain drive three-speed transmission system (*i.e.*, the ratio of the power given off at the crankshaft to that which reaches the back wheel) is about 90% on top gear and about 75% on the other two gears.

Volumetric Efficiency.

This is an entirely different matter from either of the two efficiencies that we have already discussed, and may be defined briefly as the ratio of the charge taken in by an engine on its suction stroke to the charge it ought to take in. Thus an engine of 500 c.c. swept volume or capacity should theoretically take in on each suction stroke 500 c.c. of mixture. Actually, however, the amount will be in the neighbourhood of 400 c.c., meaning a volumetric efficiency of 80%.

It should be obvious that while the volumetric efficiency has an important bearing on the ratio of power output to capacity it is quite a mistake to speak of the volumetric efficiency of an engine as the ratio of power output to capacity, yet this mistake is one of very common occurrence among those who might reasonably be expected to know better. A simple unequivocal name for volumetric efficiency is "pumping capacity."

The main questions involved in designing an engine to give a high volumetric efficiency are the design of such details as induction ports, inlet valves, and valve timing, etc. The question of exhausting the burnt charge has, of course, also an important bearing on the matter, as fresh gas cannot be introduced into a cylinder until the used up charge has been removed, and a high scavenging efficiency is almost as vital as a high induction efficiency to secure high volumetric efficiency.

SIDECAR WHEEL SPRINGING.

A Dutchman's Original Wheel Springing System.

HOLLAND is not a country from which one expects many radical improvements in motor cycle design. Mr. C. H. Bouvy, of 50, Noord Einde, Delft, however, sends the accompanying photographs of a sidecar wheel springing system he has patented, and we quote his own description as follows:

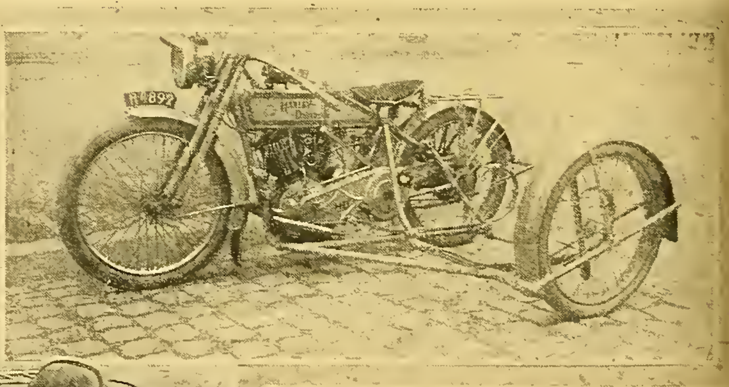
"As can be seen from the photographs, the wheel of the sidecar is fixed to the frame by means of a pivoting fork, which surrounds the wheel and slants upwardly, the frame being supported at the wheel side by a pin which extends from fork and floats between helical springs enclosed in a tube that extends upwards from the frame. By this arrangement the wheel is entirely surrounded by the fork, and is thus prevented from slipping.

"The tube enclosing the helical springs may be adjusted upwards and downwards for the purpose of regulating the height of the sidecar in relation to that of the motor cycle, whereas the tension of the springs may be adjusted likewise.

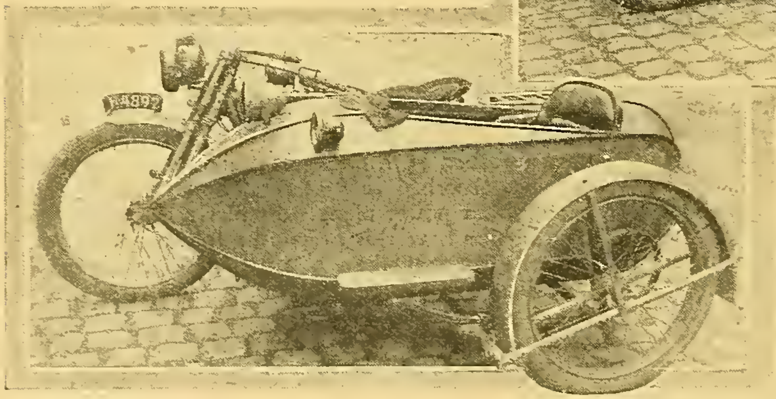
"By the peculiar construction of the pivoting fork, slanting upwards, a low and strong frame is obtained, the tubes of which are all in one plane, without bends, with the exception of two portions bent in order to reach the fastening lugs of the motor cycle."

In the opinion of the designer, this springing system would cost little more to manufacture than the ordinary sidecar chassis. He also assures us that he has experimented quite exhaustively in the matter, and has actually tested this design for some 3,700 miles, and has obtained complete satisfaction from it. Mr. Bouvy mentions the fact that he is willing to negotiate for the sale of the patent, and would be pleased to get in touch with any English manufacturer who is interested.

The whole scheme certainly seems to contain possibilities, and we see no reason why it should not give every satisfaction in service.



The body of the sidecar removed to show construction of chassis.



The clean design of the sidecar is a feature which immediately makes appeal to those whose inclinations are in the direction of a "sporting" outfit.

QUESTIONS & REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Record Speed.

I should be very grateful if you would tell me: (1.) What is the British record speed of a motor bicycle on the track? (2.) Who made that record and where? (3.) What type of machine was used?—J.G.

(1.) The fastest speed accomplished officially by a motor bicycle is 93.48 m.p.h. (2.) The rider was Sidney George, who accomplished this speed on Brooklands Track on May 2nd, 1915. (3.) The machine was a two-cylinder eight-valve Indian.

A Flooding Carburetter.

Would you kindly give me your advice how best to remedy the following defect in my Junior Triumph? If the machine is at a standstill, with the petrol turned on, the petrol drips from the float chamber of the carburetter, apparently through the gauze and round about it.—A.C.S.

The trouble is probably due to a piece of grit on the needle valve seating. If the needle is lifted off and pressed down on its seating, and at the same time turned round between the finger and thumb, this may clear the obstruction.

Electric Lighting with a Dry Battery.

I have a 6 h.p. Campion-Jap sidecar outfit. The head lamp fitted to the motor cycle is an F.R.S. with an acetylene generator. I have procured a Hellesen battery and an F.R.S. adapter. I should like to know whether you think it advisable to run the head lamp and the sidecar lamp from this battery, and, if so, the best means of doing it. How should I connect up the wires?—W.J.H.

You will be putting rather a heavy strain on a dry battery if you use it for the purpose of lighting two lamps. If, however, you wish to make the experiment, you may use two bulbs, the sum of whose voltages is equal to that of the battery, and wire them up in series; or you may use two bulbs, the voltage of each of which is the same as that of the battery, and wire them up in parallel. Electric lighting for both sidecar and solo machines has been dealt with in *The Motor Cycle* of December 27th, copies of which can be obtained on application to our publishers, Messrs. Iliffe and Sons Ltd., Tudor Street, London, E.C.4.

Free of Duty Petrol.

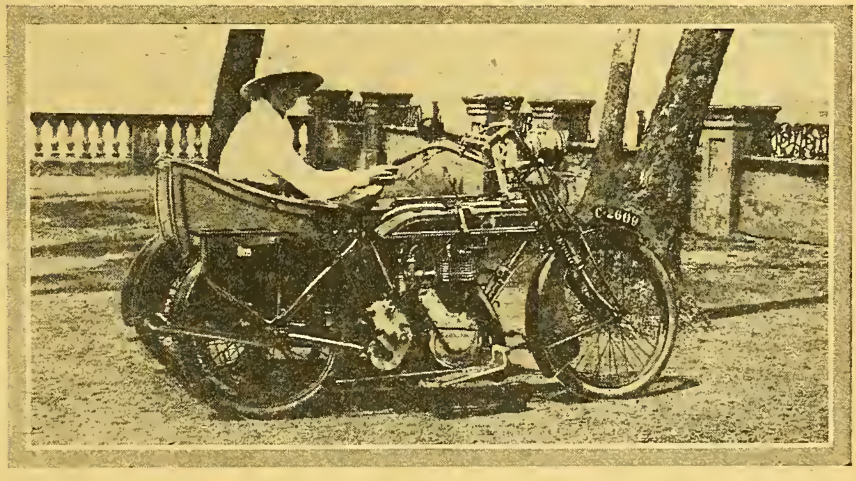
I have been doing voluntary ambulance work on air raids for the last three years, and paid for my own petrol, etc. The Petrol Committee have allowed me a permit of four gallons for two months, but it is not duty free. Should I not get this duty free? Other ambulances get petrol free, one shilling an hour sustenance allowance, and one penny a mile tyre allowance. I have to pay for my own petrol and the tax on it. Also shall I have to take out the local taxation licence for the year? Am I permitted to ride out on my machine when there are no raids in progress without fear of conviction? Also am I allowed to take out my wife and child for the benefit of their health once a week?—T.E.P.

Yes; certainly you should get petrol duty free for this purpose, and we should recommend you to communicate with the Petrol Controller's Department, 19, Berkeley Street, London, W.1. If the machine is used solely for ambulance work you will be able to get a refund of the licence at the end of the year. If, however, you use the machine for other purposes, then, of course, you are liable, not only for the local taxation licence but also for the petrol duty. Free petrol will only be allowed to you if you are driving an ambulance, but would probably not be allowed in the case of a motor cycle used in connection with ambulance work. You are not allowed to take out your wife and child or use motor spirit or gas unless you are using it for one of the purposes mentioned under the Motor Spirit and Gas Restriction (Consolidation) Order, 1918.

Petrol Permits and Licences.

(1.) Shall I be allowed to use my motor cycle and sidecar (registered in my name) while on leave? If so, (2) where do I apply for a petrol permit? (3.) Will a local garage supply me with petrol should I obtain a permit? (4.) Will it be necessary for me to take out ordinary Revenue and driver's licences (for ten days), both having run out in 1916?—F.H.W.

(1.) If you are expecting to obtain leave after service Overseas you should be successful in obtaining a petrol permit. (2.) You should apply to the Petrol Controller, 19, Berkeley Street, London, W.1, stating the full circumstances of the case, and the day on which your leave is expected to begin. You should make application about three weeks before you need the permit but, if this is impossible it would be far better if you could make a personal application, as otherwise you probably would not get the permit until it is too late to be of any use. (3.) Having obtained the permit, you will have no difficulty in getting petrol at any ordinary garage. (4.) You are liable for both the local taxation and driver's licences.



A 3½ h.p. Premier combination owned by Mr. N. H. M. Ferguson, of Colombo, who reports a good opening for motor cycles in Ceylon.

Petroil Lubrication.

Being the possessor of a 2¾ h.p. single-gear two-stroke, I wish to know what proportion or quantity of oil should be mixed with petrol, per gallon, taking into account a medium proportion of hill work. Please let me know the correct method to adopt in applying for a petrol permit.—F.W.E.

The correct proportion of oil to petrol is half a pint of oil to one gallon of petrol. Mention fully the circumstances of your case—that is to say, why you are applying for a petrol permit—and ask for a form to be sent to you. If the Petrol Controller's Department (19, Berkeley Street, London, W.1.) will see its way to grant you a permit, you simply have to fill up the form and pay the petrol tax in advance.

Engine will not Run Slowly.

I am the owner of a 3½ h.p. James twin fitted with a patent lubricator. This lubricator has never worked correctly since I received the machine in June of last year. The drops do not drip continually, but only drop slowly now and then, so I have had to resort to the pump. Sometimes when I use the pump a good deal of oil will collect in the bowl of the sight feed, and air bubbles will be seen forcing their way through from the crank case. Can you tell me how to cure these troubles? I have cleaned out the ball valve at the crank case. Do you think the spring of this is too strong? The engine has never run slowly enough (Amac, 23 jet). I have eliminated any air leakage there may be. The engine starts easily enough, so I presume that air leaks are not the cause of the trouble. I have tried a 25 jet, but this does not help much. I thought of fitting a by-pass, and think of making one myself. Would an ordinary jet led from the float chamber to the inlet pipe be sufficient? A friend states that I should require an arrangement to cut out the by-pass while the engine was running at the usual road pace. Is this so? Do you think the timing of the ignition has anything to do with the slow running? —V.P.

Possibly the trouble is due to your using too thick an oil. The symptoms described seem to imply that the spring in the ball valve is not quite strong enough. The fact that the engine does not run slowly is probably due entirely to the carburetter setting, and we can only suggest that you try some other jets and adapters. The fitting of a by-pass would be somewhat difficult. It usually consists of a rather small jet in a narrow orifice, so that a very small quantity of strong mixture is drawn up while the engine is running slowly. As the speed increases the throttle should be arranged so that the throttle, when raised cuts off the by-pass and allows the ordinary jet to come into operation. This would be rather difficult to arrange with your particular type of carburetter, but we daresay it could be done. We should not think that the timing of the engine is affecting the matter at all, although, of course, it would be quite capable of preventing slow running if it were wrong.

Magneto Lubrication.

I should be greatly obliged if you would kindly let me know: (1.) How to lubricate a U.H. magneto. I have one, and there are no oil holes. (2.) Is oil mixed with petrol a satisfactory lubricant for a two-stroke motor cycle? (3.) Which is the best method of lubrication for two-stroke motor cycle: oil mixed with petrol, pump feed or drip feed?—W.K.

(1.) The ball bearings in the magneto in question are packed with grease, and consequently do not need lubrication for an almost indefinite time. (2.) From the lubrication point of view the system is fairly satisfactory, but from the point of view of cleanliness it is very much the reverse, being exceptionally messy (see the notes on the subject in the article on lightweights in the issue of *The Motor Cycle* of March 7th, page 235). (3.) We should say that pump feed or drip feed would be the more satisfactory on the whole.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

THE NEED FOR ECONOMY.

Owing to the present drastic restrictions on the import of paper, the most rigid economy is necessary, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week, thus avoiding chance buying, which may lead to wastage owing to copies being left unsold.

Engine will not Start when Warm.

(1.) I have a Sun-Villiers two-stroke, which will start from cold with a pull of the back wheel after priming and flooding the carburetter (Amac, 27 jet), but when hot or only just warm I cannot start it at all, but have to wait until it gets cold again. (2.) Should there be an asbestos washer between the cylinder and release valve where it screws in? If so, would the absence of this cause the above trouble? (3.) When I open the throttle to its fullest extent, violent backfires occur, which stop the engine unless I half-close the throttle, after which it runs beautifully. (4.) Will you please tell me the correct mixture of oil and petrol under the petroil system? (5.) How should the ignition be timed? —A.B.

(1.) The symptoms which you describe are somewhat difficult to explain. It is just possible that the trouble is due to condensation on the plug points, or to the size of the jet not being correct; consequently there is too strong a mixture at starting when the engine is warm. You might, therefore, try a smaller jet. (2.) Probably there should be, the idea being to keep the release valve compression tight, but if there were a leakage here we do not think it would affect the engine starting only when warm. (3.) This also seems to indicate that the jet is too large. (4.) The correct mixture is half a pint of oil to one gallon of petrol. (5.) Time the engine in the following manner: Variable spark—Place the piston exactly on top of the compression stroke, and connect up the magneto with the points just broken and the ignition lever fully retarded.

Altering the Balance Weights.

My two-stroke engine has a solid crankshaft with two loose plates bolted on each cheek; these plates weigh 2 oz. each, and, there being only $\frac{1}{16}$in. clearance between crankshaft and crank case, the bolt heads are no thicker than a penny. These plates have often worked loose, and once jammed the connecting rod. They appear to me to be a nuisance. A friend suggests removing them, and, if it has much effect on the balance, to remedy it by putting a weight on to the flywheel, which is very heavy, and has two small holes doing nothing on to which I could bolt such a weight. But what effect would it have? Could it hurt the engine if I tried it? The engine seems free enough without these plates, but I have not tried it under power.—T.S.

If you remove the plates in question you will upset the balance of the engine, as they are evidently balance weights. It ought to be possible to secure them so that they do not come loose. You might try rivets instead of bolts. The holes in question in the flywheels are also for reasons of balance, and if you alter the position of your balance weights and fill up holes which have meant the removal of superfluous weight, you will upset the engine balance altogether.

RECOMMENDED ROUTES.

Middlesbrough to Blackpool.—S.G.

Write for free Booklet, "Testimony," which gives you the opinions of users of Beldam Tyres. They know!

NO matter how rough the road—no matter what the condition of its surface, you can feel assured of the utmost tyre satisfaction if your Motor Cycle is shod with

Beldam

All - British Tyres

The Beldam V Steel Studded Motor Cycle Tyre is an all-roads-all-weathers tyre. Its rubber tread and steel studs are one level surface (studs are indented), and therefore it "toils not" in mud "neither does it spin" on hard roads. So much for grip. As to wear:—Rubber is thickest where wear is greatest; the side projections support this thick strip of rubber and they also allow lateral displacement. This accounts for the fact that Beldam Tyres do not easily get cut or punctured. Any user of Beldam Tyres will confirm this

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☛ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

CAN WE ASSIST YOU?

Knowing the extreme difficulties at present prevailing as regards the shortage of parts, etc., we have acquired the following **Parts**, and beg to offer same to Motor Cyclists at exceptionally low terms. The goods mentioned are offered on the money back if not satisfied principle, cash with order, and subject to being unsold. Those requiring reply, please enclose stamp. When ordering, postage must be included. Excess, if any, will be refunded.

1 pair 1915 Scott Forks, complete, **£2.** Chain Links, ⅝in. × ¼in., half link, **8d.**; spring link, **6d.** 1in. Forward Belt Fasteners, **1/3** each. Bowden Cable Clips, 3 at **1d.** C. & A. Washers, for most engines, **2d.** each. Compression Tap C. & A. Washers, **1d.** each. Bowden Cable, carb. and brake sizes, **6d.** yard. Low-tension Wire, **6d.** yard. H.T. Wire, **1/-** yard. Lamp Tubing, **1/-** yard. Mudguard Bridges, **4d.** each. Stays, **6d.** each. B.S.A. T.T. Pulley, adjustable, 6in. drilled, **10/-.** 28×3 tyres, very heavy, at half makers' prices. Tubes, 26×2, **6/-**; 2¼, **7/-**; 2½, **8/6.** Motor Cycle Front Hubs, ⅜in. spindle, **4/-** each. A few Car Hubs, No. 1, in pairs, at **14/-** pair. Rims, 28×1⅜, beaded edge; 28×3 ditto; 650×65 ditto; requirements quoted for. Steel tubing, 1 1/16in., 1⅛in., 1¼in.; all gauges. Double Waterproof Khaki Twill, 60in. wide, new, but slightly soiled, **5/-** yard. Phosphor bronze, chilled bush metal, **2/-** lb. Files, assorted, brand new, 6in. to 12in., **7/6** doz. Gas Trailer and Bag, 6ft. × 3ft., slightly used, **£12.** 9 Gas Trailers, less bag, complete with tyres, **£5 10s.** each; suitable for carrying goods or gas. A few up-to-date Sidecar Bodies. 7ft. 4in. Lyso Belting, 1in., **6/6**; 7ft. 6in. ¾-belting, **8/6.**—Apply **Finished Stores, Henderson Sidecars, Aero Works, Fitzwilliam St., Sheffield.**

Photography and FOCUS

Every Wednesday Twopence.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

TRAIN YOUR MIND.

Mind-training is absolutely essential to every-one who wishes to succeed in life, or to make the most of his natural gifts. The Concentro Course, "Scientific Concentration," is the finest all-round system of Mind-training in the world, for it develops all your faculties. It increases enormously your powers of Attention, Observation, Memory, Will-power, and Thought-control. It shows you how to apply concentrative methods to Reading, Thinking, Conversation, Public Speaking, Public Performances (playing, singing, and games of all kinds). It shows you how to overcome Bad Habits, Self-consciousness (Blushing, etc.), how to increase Self-reliance, how to influence your fellow-men, how to succeed in business, and how to study effectively. It gives you confidence in yourself, and a much surer hope of success, and gives you courage to meet any trial and difficulty in life. Send to-day a 1d. stamp to the CONCENTRO CO., 59, Central Buildings, Wallsend, Newcastle-on-Tyne, and they will send you free their descriptive Booklet on "Scientific Concentration," and the testimony of their students; also the testimony of Famous Men and well-known Editors as to the value of "Scientific Concentration," which is now being practised by thousands of students in every part of the civilised world. Send to-day for this Booklet—NOW.

A New Departure.

FOR introducing an aviation section to *The Motor Cycle* we need offer no apology to our readers; in fact, the interest displayed by motor cyclists in air-motoring since the new feature—Flying Facts and Theories—was started in this journal fully justifies such a policy. It is an indisputable fact that motor cyclists make the best pilots, and nearly all pilots are therefore motor cyclists. Flying, therefore, may be said to come almost within the sphere of this journal.

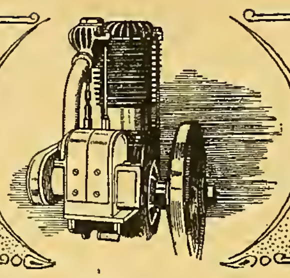
The need for dealing with flying in non-technical language is clear, and, judging from the number of our readers who desire to join the flying services, it is evident that we should be in a position to give them all the information possible, and so continue to help the country in the same successful manner as when this journal recruited over 10,000 readers into the R.E. Signal Service, the M.M.G.S., and the Tanks. Notwithstanding the introduction of this feature, the motor cycle in its several forms will in no way be neglected; there will be no dearth of motor cycle news, and the subject will be treated to the same extent as before, but with this difference, that *The Motor Cycle* proper will not contain articles on flying, but will deal mainly with that vehicle, the development of which it has so successfully fostered without ceasing through times good or difficult for the past fifteen years.

Let us consider why the young motor cyclist is so enthusiastic about flying, and, when he has mastered the rudiments of aeronautical work, makes so good a pilot. The reasons are not far to seek. The youth who rides a motor bicycle is generally in fine condition—motor cycle riding brings this about—he drives a self-propelled vehicle which has not only to be ridden but also driven; he subconsciously balances the machine, and, at the same time, uses his brain to control and get the best out of a beautifully made little engine. Not only is the body but also the mind kept fit, the nerves are braced and steadied, and the rider eventually possesses the much-desired *mens sana in corpore sano*. Hence the trained motor cyclist—fearless, skilled, and a good amateur mechanic—is well supplied with useful knowledge before he has learnt a single lesson in flying or listened to a single lecture on aeroplane engines.

The desire to fly is present probably in the mind of every motor cyclist. How often has the feeling come over the rider, seated on a fast, smooth-running machine, hurtling along at a good pace on a straight and undulating road, when hills are annihilated, that, while shooting up some stiff gradient, it would be joy indeed to continue one's course and sail into the clear air, leaving the road and its bumps behind, and soaring forward straight across country until one's destination is reached? Many, also, have dreamt of a motor cycle with folding wings, which could be mechanically extended as one travelled along, and would enable the machine to leave the ground and fly away into space. The artist who, some years ago, illustrated the idea in *The Motor Cycle* was not alone in his imaginations. In these days of flying progress it would be rash to prophesy that such a feat would not eventually become feasible, but we simply quote the idea, without pretending to any knowledge of the future, to show how the desire to fly is latent in practically every reader of this journal.

Our object, therefore, is by means of this section to help the embryo pilot in his education, to keep him up-to-date with regard to the Air Services, so that he may join either the Service or a Cadet Training Corps and eventually obtain a commission. Above all, we desire to deal with the subject in a simple and comprehensive manner, so that the merest novice may learn with ease. By thus treating aviation in all its forms we feel that we are serving the country, and if we ever so slightly assist the nation in its hour of need we are content.

Two-stroke Engines and Efficiency.



A Suggestion for Increasing the Efficiency of Two-stroke Engines, involving the Use of a "Displacer Piston."

THE present interest in and desire for more highly efficient engines on the part of the motor cycling public and at least some manufacturers, prompt me to the consideration or reconsideration of that most flagrantly inefficient engine—the popular two-stroke. The two-stroke has won its way to popularity, not because of its efficiency, but because of its simplicity and the consequent low first cost. Many people first take up motor cycling as an experiment, therefore they want something the first cost of which is low, and preferably something that is comparatively simple. But these one-time recruits now demand something better. Many of them still want the even torque of the two-stroke but are not eager for the complications of a four-stroke twin that would secure it to them. What most motor cyclists really want is a far more perfect and far more powerful single-cylinder two-stroke. For the inefficient two-stroke becomes even more inefficient with an increase in size, so that a powerful single-cylinder two-stroke is practically non-existent. As has been pointed out by many—if the two-stroke were only as volumetrically efficient as the four-stroke, then size for size it would be twice as powerful.

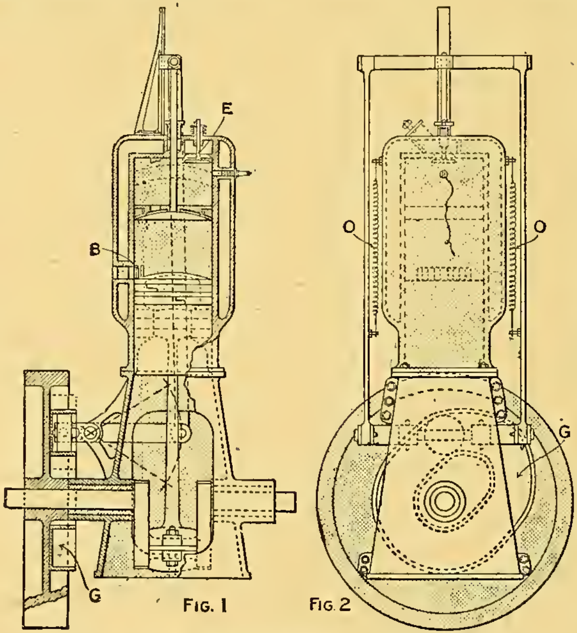


FIG. 1 FIG. 2

The two-stroke engine designed by the writer of the accompanying article. Fig. 1, a part sectional elevation of the complete engine; fig. 2, the special cam arrangement operating the displacer piston that secures complete scavenging and a fuller charge.

The problem, then, is how to make it at least equally efficient. Some manufacturers attempt to attain this end by some form of improved (and incidentally more complicated) or added valve gear. The full efficiency that is demanded can only be got by a thorough scavenging of the exhaust and introduction of a full charge after the scavenging. In present-day two-strokes it is doubtful if anything like a full charge is drawn into the crank case, because its capacity due to clearance for crank, etc., and the cup-like piston, make a strong vacuum impossible. For the same reason a strong crank case compression is not obtainable, and the resistance offered by the exhaust against the incoming charge, not to mention that part of the charge that finds its way out of the exhaust port, makes a thorough scavenging of the exhaust and a full uncontaminated charge a thing impossible.

Even in the early days, there was a design patented that in its purpose accomplished that which we are now seeking. A patent for this design was first taken out in 1902 (No. 10,700, Arthur Thomas Collier). In 1912—ten years later—not having heard of this, I also invented and patented a very similar design now made public for the first time. The final search of the Patents authorities brought this previous design to my notice, and owing to its similarity in the main essentials I dropped mine entirely.

No doubt these designs, or at any rate the first, was like a thing born before its time, and perhaps now forgotten even by the inventor himself; whether any engines on these lines were ever made I have been unable to discover. The design presents difficulties, but not, as I imagine, insurmountable ones. The drawings I submitted to the Patent Office are here reproduced, and it will be seen that the chief feature consists in the introduction of an additional piston termed the displacer piston. This light piston remains at rest against the top of the cylinder during the firing stroke until the usual exhaust port B is uncovered slightly, when it then descends, travelling at twice the speed of the main piston meeting this except for a clearance just as the exhaust port is once more nearly covered by the main piston (see fig. 1). This light displacer piston, owing to its greater speed, returns to its place of rest well before full compression is reached. In its downward motion it sweeps out the exhaust through the port B and simultaneously draws in a free charge behind it through the valve E. It will be noticed that this displacer piston has no heavy duties to perform, all the compression and firing being borne by the main piston as usual. It could, therefore, be very light in construction. As shown it is operated by a cam G on its downward journey, but returned by means of coil springs O, some clearance being allowed in the outer ring of the cam (see fig. 2). The height might make a special form of petrol tank necessary.

A. G. MACKAY.

OCCASIONAL COMMENTS.

By "IXION."

My Favourite Rough-rider Mount.

As a chronic rough-rider, I read with very special interest "Wharfedale's" criticisms of various machines employed by him in a bad winter's mudlarking. I do not profess to be a neat rough-rider: for example, I do not shift my pipe to between the two front dead centre teeth on grease, as Major Watson's famous crack used to do: I pay less attention to the pretty-pretties of driving in winter than in summer, and am generally content so long as I can keep upright and warm. My own favourite mudlarker was a T.T. Rudge. I do not like anything lighter for bad surfaces: the little 'uns bounce too much, and a big jolt that finishes up obliquely on a patch of grease is apt to cause a wild skid. Neither do I like anything heavier, for in long distance work the strain of holding up 3 cwt. or so is apt to tell on one's wrists. The earlier Rudges were just the right weight, and were beautifully balanced. Mine had a handle-bar which was wide enough to give plenty of leverage without splaying one's arms overmuch, low enough to throw a little extra weight on the front wheel without being so low that it could stab the tank if you went over. Unfortunately, for military work anywhere, and for winter roads in most peaceful areas, we need a gear box, which my pet Rudge did not possess: and I cannot say that I have ever found a mount of the go-anywhere order which struck me as ideal for the most exacting winter work. I always turned down the beautifully balanced Scott, for the simple reason that a machine is simply bound to tumble once or twice in a hard winter's work, and the Scott had a number of expensive low down fitments which were always crumpled when it spilt.

A Case in Point.

I remember watching the late Ivan Hart-Davies "shake" a well-known amateur on a Scott on a summer day when a little rain had fallen. "H.-D." was a very fine cross-country rider—much better than his companion, with whom he intended to have a little fun. He volunteered to lead the Scott rider over a certain short cut of about fifty miles, when the pair of them were returning to headquarters after a hill-climb. "H.-D." made the pace a cracker, and put in his best corner work. There was a thin film of damp on the road surfaces, and the Scott rider purled over some five or six times on the run. To quote a bomb-tester's report, "the fragmentation was good." The poor man-handled Scott wanted about £5 worth of new bits when it got home: and its rider's legs had hung without bottom support for the last ten miles, like the undercarriage of an aeroplane. For rough work, give me a 'bus with cheap and simple underworks, which can be kicked straight after a fall, and replaced for a shilling or two if necessary.

What about Tyres?

I suppose it is a point of honour with the genuine rough-rider to scrabble along on any old tyre. I plead guilty to a great weakness for Roms in fast winter work. Their rubber cross-bars give you a hold on hard frozen roads, and the steel studs bite well on grease. I am not partial to these combination covers in summer: naturally, they are not as long-lived as an all-rubber tread, and they are not ideal for smooth sun-baked roads. But it is astonishing with what safety they keep you vertical at speeds on atrocious surfaces in winter.

Spring Frames in Winter.

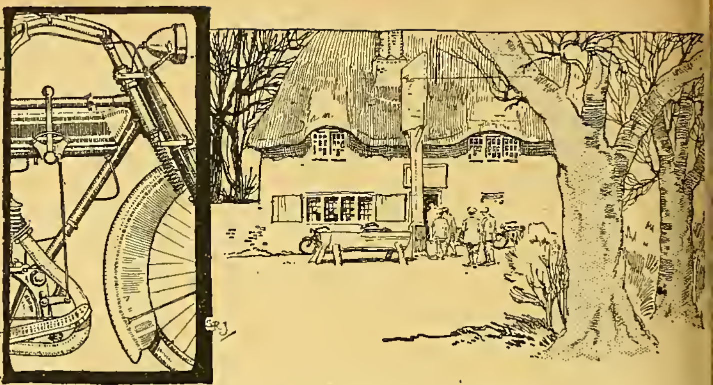
I doubt whether "Wharfedale" can have tried out a first-class spring frame in rough-riding conditions; if he has, he must have used it on truly impossible surfaces. He turns them down because they give no more comfort than the Scott, and bang your spine over big bumps. If a spring frame bangs your spine, what price a rigid frame? I can introduce our contributor to spring frames which are possibly dangerous from an opposite standpoint. They smooth out the road more than is safe when serious skids are prevalent. I mean just this. If I take out my pet spring frame in winter, I presently realise that I am riding too fast. I start the trip with a little wind up, being out of practice on grease. I slither along very comfortably for a few miles, realise there is no danger, and put the pace up. Presently, whilst holding the machine a little carelessly, I take a springbok leap over a big bump, and come down on a patch of bad grease—more or less sideways across a slight camber, with the front wheel not held firmly enough; and all at perhaps 35 m.p.h. I have to fight the machine like a tiger to keep upright, and I realise that the comfort of the spring frame has tricked me into riding somewhat too fast and the pace drops again to its former rate.

The Engine for Grease.

Nor do I agree that any particular type of engine is pre-eminently suitable for rough riding. On paper, of course, an engine which gives perfect torque and demands no gear changes is the thing. In actual practice there is not a radical difference between the torques of the single-cylinder, the two-stroke, the flat twin, and the V twin, and they all want a gear box astern of them. Such contrasts as exist between these four types of engine from a rough-rider's standpoint can all be levelled up by using a suitable gear ratio, combined with a good type of gear change. The single-cylinder four-stroke is obviously the worst, but if we gear a 3½ h.p. Rudge down to, say, 5½ h.p. on top, we can want nothing better. Earlier in the war, when I daily did a lot of vile rough riding, including moorland tracks with a grade of 1 in 4, I used to put my A.B.C. down to its 9½ gear, on which I could climb practically anything, and vary my speed from two to forty miles an hour without taking a hand off the steering bar. Alternatively, with an inflexible engine, it is essential that the gear controls shall be good. The rough rider cannot conveniently spare a hand for a tank gear lever, and at the same time perform delicate toe-twiddles on a clutch pedal when his mount is skidding and bouncing heavily.

THE DOUBLE-ACTING ENGINE.

Possibilities of a Design combining the Advantages of Conventional Two and Four Strokes.



THE problem of the two-stroke engine is a fascinating one, and for several years a large number of engineers have been under its spell. Probably the very simplicity of this type of engine has been responsible for its comparatively slow development, as in the simplest designs, such as the Levis, Connaught, and other machines of that ilk, there are only three moving parts, while the impulse effect is as with a two-cylinder engine of the four-stroke type. Designers have endeavoured, to obtain double the result for less than half the cost of a four-stroke engine. In the writer's opinion this appears to be asking too much, and, I think, designers should be content, for the time being, if they obtain double the four-stroke result at the *same* cost or the same four-stroke result at a reduced cost.

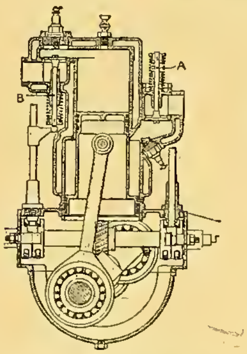


Fig. 1.– The Boudreaux-Verdet bi-duplex engine, having truncated pistons, both parts of which are utilised as power agents.

Of late, however, there have been indications that designers are foregoing simplicity in design by the introduction of valve gear in order to make a two-stroke single-cylinder give the same results as a four-stroke two-cylinder engine, and so long as the added mechanism does not exceed the complication of a four-stroke engine there will be a decided advantage, provided the same results are obtained as in a four-stroke engine with double the number of cylinders.

It is rather surprising, since an impulse per cylinder for every revolution of the crankshaft is the objective, that designers have not given greater attention to the double-acting engine working on the four-stroke cycle. So far, it must be admitted, the four-stroke cycle has proved to be the most efficient, and it would not surprise the writer if six-stroke engines were developed before the two-stroke, as, for economy and over-all efficiency, the six-stroke promises to outdo the popular four-stroke. In any case there is ample evidence to show that the really efficient engine cannot be secured without the introduction of complication, but so long as the results justify the cost this is unimportant.

So far the four-stroke cycle engine has proved to have the best over-all efficiency; therefore a double-acting engine working on the four-stroke principle should offer greater inducement to the inventor and designer than the two-stroke, if only for the reason that the former principle is better understood. With a double-acting engine the number of parts, th weight, the space occupied, and the cost of productio must all be lower than a conventional four-strok engine with double the number of cylinders, which i imitates in impulse torque.

As will be seen from the following table, a double acting four-stroke will give the same impulse effec as a two-stroke, while the six-stroke appears to b entirely out of the reckoning, but it must be remembered that some engineers consider that the net resul with the benefits derived from the two extra so-calle "idle" strokes actually increases the power of th engine. That is, two impulses of a six-stroke wil give more power than three impulses of the four-stroke, hence one may imagine that the four-stroke has a least the same advantage over the two-stroke.

It is strange that almost every double-acting engine so far produced or designed has been at the two extremes of internal combustion engines, viz., the motor cycle and the marine engine. As regards the latter it is interesting to know that several successful engines are now on the market, but in the motor cycle field the designs have not progressed far beyond the paper stage. There is, however, one notable exception, the Frost engine, which we illustrated and described in our issue for February 21st.

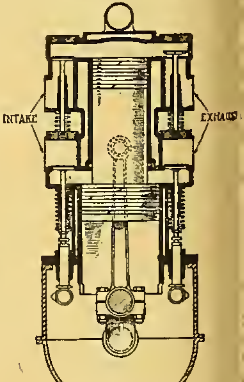

Fig. 2.—An American design of a double-acting engine, the Schoenrock.

A French Example.

A double-acting engine which created a great deal of attention at a Paris motor

The Double-acting Engine.—

shown a few years ago was the Boudreaux-Verdet bi-duplex engine, of which an illustration is given (fig. 1). This engine has truncated pistons, both parts of which are utilised as power agents, explosions taking place both in the lower and upper parts of each cylinder. The upper and lower portions of the cylinder form quite distinct chambers, so that gas cannot pass from one to the other.

The illustration does not give a clear idea of all the details of the working of the engine, as, to avoid confusion, all the valves employed are not shown.

Though the lower portion has a larger diameter than the upper, yet, as it is partly filled by the piston body at all positions in the stroke, it will be seen that it does not contain a correspondingly greater amount of fuel. The gases can only occupy the space *between* this piston and the cylinder walls, and exert their force on the flange or enlarged portion at the bottom, which carries three gastight rings.

Therefore, since each end of the whole piston receives its own impulse from a distinct and separate explosion, the effect is that of an ordinary petrol motor working on the four-stroke cycle with twice the number of cylinders. The explosions are made to alternate, so that when one occurs in the top portion the lower piston is drawing in a charge of gas which is compressed while the upper one is exhausting its waste gases.

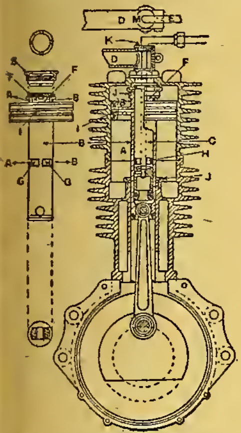

Fig. 3.—A design by Mr. T. Slaughter.

A. Double-acting cylinder.
B. Double-acting piston.
C. Sleeve inlet valve.
D. Inlet pipe.
E. Pressure-fed oil pipe and piston, etc.
F. Inlet ports in piston trunk.
G. Inlet ports in piston trunk.
H. Inlet ports in induction pipe.
I. Lubricating oil channel.
J. Screwed cap to secure piston ring.
K. Screwed cap to close end of inlet pipe.

There are two inlet valves A and two exhaust valves B in one complete cylinder—one inlet and exhaust valve to the upper and also the lower portions respectively. These are operated from a camshaft placed across the engine and driven by a worm gear off the main shaft at a point between the two cylinders.

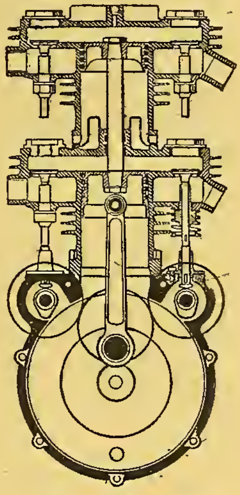

Fig. 4.—The Masters, a design possessing staggered cylinders to bring the exhaust and inlet valves side by side.

An American Design.

The illustration of the Schoenrock engine (fig. 2) appeared in an American contemporary. There is obviously something wrong with the drawing, as the valves of the lower chamber as shown would open when the charge fired. Later designs embodied rotary valves, but the illustration serves to show that the double-acting engine is not being quite neglected in the United States.

Two Air-cooled Types.

The Slaughter engine (fig. 3) is the design of Mr. T. Slaughter, of Coventry. The cylinder is closed at each end and is double acting, since an explosion takes place above the piston and below it alternately. A tubular extension forms the cross-head guide for the piston, as is the case in steam engine practice.

There are four valves. The two inlet valves are of the sleeve type. The exhaust valves are operated by rockers. The exhaust valve for the combustion chamber at the top of the cylinder has a long stem which passes through the inlet port of the lower combustion chamber.

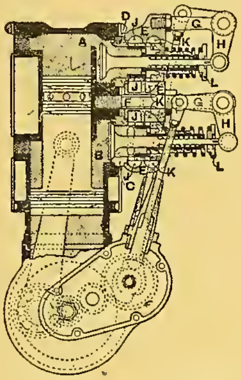

Fig. 5.—A double-acting four-stroke engine patented by Mr. L. S. Parker.

The oil feed pipe passes through the induction pipe in the cylinder head. When a port in the piston registers with a duct formed in the side of the induction pipe at the lower end of the cylinder, the oil is forced through and lubricates both the cylinder and the sleeve valve, the superfluous oil passing into the crank case.

On the firing stroke the pressure is reduced to atmospheric before the inlet ports are uncovered, by the exhaust valves being opened early. The valves, which are of large diameter, can be raised by means of a Bowden wire.

Fig. 4 is a less complicated design than the Slaughter engine, and was invented a few years back by Mr. P. G. Masters, of London. This engine can best be described as a two-cylinder tandem engine. The illustration renders a lengthy description unnecessary. At the lower part of the upper cylinder air ports are inserted to allow the ascending piston to draw in a supply of cold air to cool the piston rod and top of the combustion chamber.

Another interesting double-acting engine was recently described in *The Motor Cycle*. This is shown in fig. 5, and was the subject of a patent granted in 1910 to Mr. L. S. Parker. Each cylinder is provided with main ports A and B, these ports being fitted with fixed casings C and D, which are held in position against their bored-out seatings by the yoke piece E. This yoke piece embraces both casings, and is centrally held to the body of the cylinder by, preferably, a single bolt F. Such a construction gives considerable accessibility to the valves, since by merely releasing the bolt F the yoke piece with the casings may be bodily detached for inspection. The yoke piece E carries the screwed brackets G, to the outer ends of which are pivoted the bell cranks H, the depending arms of these bell cranks engaging the outer ends of the valve spindles of

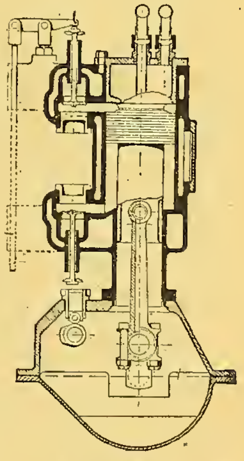

Fig. 6.—A 20 h.p. two-cylinder double-acting petrol marine engine.

The Double-acting Engine.—

the main valves, which control the outlets from the casings into the main ports A and B opening into the cylinder compartments. The valve spindles slide axially within the tubular shanks of movable sleeves, which are themselves adapted to slide within the fixed casings C and D. The fixed casings are each provided with exhaust ports J and inlet ports K, the movable sleeves being also provided with holes adapted (when the movable sleeves are in the position of the upper valve gear shown in fig. 5) to put the cylinder compartments into communication with the inlet ports K. When a main valve is lifted from its seating by the bell crank arm H, the extension of the cylindrical movable sleeve is in a position which opens the exhaust port. The movable sleeve thus acts as a slide valve controlling the inlet and exhaust ports. and is subsidiary to the main valve.

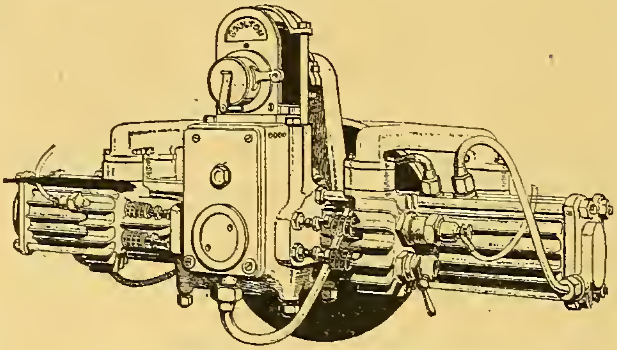

Fig. 7.—The Frost four-cylinder—the latest production in double-acting engines.

Two-step Cam.

The cam is provided with two circumferential steps of different radial depth, and as the cam rotates the action of the lower step is to lift the main valve partially off its seating, this action being timed to take place when the exhaust stroke should commence The same movement of cam and the bell crank H which has thus partially lifted the valve, has brough the collar L against the end of the sleeve, and th exhaust is now open. Further rotation of the car brings the higher step into action, thus opening th valve still further and causing the movable sleeve t shut off the exhaust port and open the inlet, as show in the drawing. The cam then permits the main valv and sleeve to be returne to the closed position.

Fig. 6 is the design o an engine built for marin purposes by Mr. S. E Hale, of Kingston. Thi engine comes nearer t steam engine practice tha any of the preceding designs, inasmuch as bot sides of the single pisto are used.

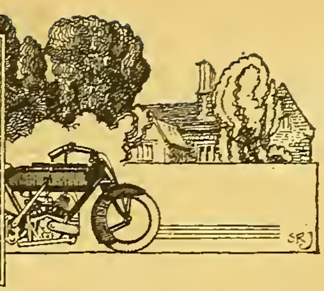
Fig. 7 is the Fros tandem four-cylinder fla engine—perhaps the mos modern example of th double-acting engine.

With the increased knowledge of engine coolin and metallurgy obtained by our engineers durin the war there seems to be promise of the double-actin engine receiving greater attention in the future, whe the torque advantages of the two-stroke would b combined with the over-all efficiency of the conventional four-stroke engine. VEDETTE.

* * *

IN THE LAND OF THE PYRAMIDS.

A despatch rider and his W.D. Triumph in the Egyptian Desert. In the background is the Sakkara Pyramid, said to be the oldest in existence. Cheops, the largest in the world, is 5,600 years old, but Sakkara is much older, and it was probably well over 6,000 years ago that this great monument was erected.



DIVERGENCES IN DESIGN.

A Comparison of Detail Work in British and American Motor Cycles.

THE mythology of the Greeks did not produce a more successful "apple of discord" than motor cyclists have discovered in the never-ailing bone of contention, American *v.* British practice, and it is a great pity that it has become the fashion for certain people immediately to construe criticism as direct attack, and to adopt the customary method of discounting the defects of one school of design by pointing out the deficiencies of *other* parts of the opposing school—a method of arguing in a circle which advances the whole subject not one iòta.

The only satisfactory procedure on which to base comparative criticism is to take each detail of the respective mechanisms and balance one against the other, and so doing leaves no doubt that the commendable features of British design show a sufficient preponderance over the American to indicate that we have less need to modify our specifications according to their ideas than they to modify theirs to ours, always supposing, of course, that it is the great proportion of the home market for which we are catering, *i.e.*, for that large class known as "the average user."

Engines.

Considering power units: Despite his experience with the type as a heavy tractor engine, the American has not yet awakened to the horizontal twin as a motor cycle engine, and, notwithstanding his unnumbered two-cycle boat motors, he has never refined the type for light road transit as we have.

Of four-cycle engines it may truly be said that our single-cylinders are much further in advance of the Americans than his V twins excel ours; in so far as internal arrangements go, the large twins are generally good in design, material, and workmanship, and commendably superior to our own engines both in smoothness and silence of operation and in their manner of dealing with the exhaust.

They nevertheless tend to a certain flimsiness in some of the accessory external fittings, as, for instance, overhead valve mechanisms, inlet domes and cages, valve lifters, and fuel and oil piping and their unions—seeing that the U.S.A. is the home of o.h.i.v. it is curious that none of their manufacturers has designed a method of housing this part so simply efficient as that used on our own Rudge, or Enfield, while the enclosure of timing wheels inside the crank case persisted in many years after the same thing was abandoned in British practice.

In mounting the engine in the frame it is debatable whether the loop frame system would not be better than our own if it were carried out by British manufacturers, but in the States the advantages have been nullified by the use of small diameter bolts and light gauge plates with resultant engine "dither" through wearing of the holes after a couple of seasons' use; our own machines, even the old buck-jumping singles, generally retain the engine in the frame for many years with praiseworthy rigidity.

Frames.

While frame breakages appear to be less frequent among the Americans than with us, I have both seen and heard of a far greater proportion of that infinitely more dangerous trouble—front fork breakage.

The American frames hold together satisfactorily, not so much by virtue of an inherent excellence of design, but because of the quality of the materials employed, and British manufacturers would be well advised to follow suit and abandon the malleable casting once and for all.

The American, however, could never be accused of using much science in his frame designs, and it is, indeed, extraordinary that the country which produces the Ford chassis—so remarkable for the manner in which every ounce of material is apportioned to its particular duty—has failed to give us anything even tending towards the straight-tube ideal which our own designers are at last inevitably acknowledging.

Front Forks.

Whilst our designers have endeavoured to evolve a spring fork in which short bearing pins are eliminated and all working parts are above the wheel, the American leaves his bell cranks and shackles where they are exposed to the mud from the front wheel.

Where is there an American gear-change lever to compare with that of the 1913 Triumph, for example, or where the mudguards equal to those of the Enfield, Clyno, or A.J.S.?

Despite the excellence of the American hubs with their large balls, where are their detachable and interchangeable wheels, with which we are now familiar?

Clutch and Gear Control.

Interlocking clutch and speed controls are no doubt excellent safeguards against mishandling of the gears, but they are a crude method of arriving at a foolproof mechanism; while America cannot show anything in gear-striking tackle to excel the originality of the Douglas or the simplicity of the B.S.A. or Sunbeam.

The question of chain-guarding has really not occurred to the American in the same sense as it has, say, to the designers of the P. and M. or Clyno.

One might go on *ad infinitum,* finding good and bad on each side, but one cannot get away from the fact that, apart from the engine, the general arrangement of the American machine, until recently, has been marked by a crudity which tends to refine itself by a process of Anglicising the fittings.

D.H.S.

"PIP EMMA" MATCHMAKER

The Soliloquies and Observations of a Motor Cycle in the hands of a Flying Corps Despatch Rider. The words used in the article are the terms applied to various letters in field signal work so as to avoid ambiguity, *e.g.*, A is known as ak, B as beer, and D as don to distinguish them from other letters of similar sound.

"There's a girl on me now," said 6000.
LYNN

"CORP., I'm taking the mails to-night!" He uncovered his six-foot length from my flapper-bracket as he spoke, and threw a crumpled envelope at my cousin Douglas, who lay untyred on the other side of the garage.

The Corporal raised a sandy head with a far-away gleam in his eye. "Now what the devil do you want in Salbershot again, Pip? It's not your turn!"

Pip is my master, temporarily, and he is a Don R. He is christened Pip after me, for my name is Pip Emma. He should be a first Ak Emma, but he isn't, because somebody large and braided and Sam Browned found his daughter tidying her hair with the aid of a Leyland reflector and my front lamp!

"My little Corporal," quoth Pip. "If I don't get the Salbershot run to-night it will bring my grey hairs in sorrow to the grave! There's a maiden aunt I have, and she's coming there to see me. I have expectations from her which unrealised will bring me to the poorhouse," and with this, and a flourish of tragedy, he ceased, and sank gracefully on to the bench beside me. Alas for effect, he also sank gracefully into a tin of paraffin.

"Strafe you," said the Corporal, as he strode across the shed and picked up a crumpled ball of paper. "I had to sign for that juice. Yes, Pip, maiden aunts always use mauve paper, with purple ink—and always use purple wax sealed with a pair of hearts and an arrow! No, Pip. Tomkinson shall take the mails!"

"He's on Zepp guard."

"Well, Billy then."

"Cookhouse fatigue."

"Gracious!—Smithy."

"Sick list. He's bobbing."

"Damn you, Pip. Where's that girl?"

"Gone with the second in command to a concert! I told you I was going to take those mails."

The Corporal scowled.

"Your luck seems in, Pip. Well, if you do go—if I *do* send you——"

"Yes?"

"You might bring me back a couple of pounds of Cailler's, and one of those ten bob Flying Corps brooches."

He filled me up with oil and petrol, and fed me with carbide and water, did my master. And then we were ready for the road.

He was "all poshed up," as we say in the Flyin Corps, in his best big pilot's gloves, and a shiny sil scarf, and I could smell Con Amores, or Abdullas in his pocket whenever he came near me. And guessed he'd been visiting the officers' mess.

I tried to tell him how much I disapproved of hi conduct in a series of loud back-fires when he trie to start me.

I hate being kick-started—all self-respecting bicycle do. I like trying to run away from people that ho along beside me. But he told me to shut up, an gave me less air.

A "Nice 'Bus" and a Well-bred Car.

Now let me tell you that I am no ordinary Pip an Emma. I was the pride of Haish Park before I joine this family, and I fondly imagine that I am the prid of our transport here. Consequently I hate bein bullied.

Pip gets a bit too important sometimes—wants coo ing down. So I shut my jaws with a snap (of carbo and refused to spark.

I very much regret to have to tell you, gentle reade what followed. His language grew so heated that warmed me up, and I had perforce to start in spite myself.

"Pip Emma," says he, as he opened me out pa a camp. "Pip Emma, we're on medical hut to-morrov Five o'clock in the morning; what, old thing?"

I really hadn't the heart to be cross with him ar longer—he's such a dear and such company. S "Pip-pip!" says I, "I like medical hut." Thoug I do have to wake up early and shake the sleep ou of my lamps. The girl clerk there is rather a go sort, and understands and appreciates me when I chaperon for her and Pip.

She says I'm a "nice 'bus."

So I put my best wheel forward in the fresh summe dusk, and the dusty hedges were a long streak white as we tore by them.

Be it as it may, we got to Salbershot in record tim leaving the little villages of the plain, all sleepy ar quiet, in our wake. We delivered our mails, and P put me to bed for a bit in a jolly old garage with couple of Crossleys.

I like Crossleys. Sporting 'buses they are; tal most things on top, and nice-natured. Not stuck like Fords or uncouth and grumbly like Leylands.

"Pip Emma."—

"Say, Emma," said "6000," an old Crossley pal of mine, after Pip had gone out. "I've got a girl on ne now." I pricked up my controls at that, for a girl in khaki had attacked me a day or two before, and had nearly finished me. However, I managed to knock her out successfully, with the aid of a few trees and things, and she was still in hospital.

"Yes—and I was three-stepping for her yesterday. Miss Smith,' says the Flight, 'one of your cylinders s missing!' 'My goodness!' says she, and I'm blowed if she didn't start looking for it round the vash!"

Farmer's Cart—Usual Story.

I groaned, for I'd heard that tale before, but re-aliated by making "6000" listen while I told her how our girls had scattered Keatings round the garage and found all the Fords on their backs next day!

It was getting near midnight when Pip came back for me. He fell over "6000's" mudguard, and woke me up with his language. These men have no respect for our feminine ears. Yes—we are feminine.

It was a topping night out, with little bright stars laughing down at Pip, who was so happy with his memories of his "maiden aunt" that he left most of the work to me. I was a little preoccupied, too. I was having an affair with my Cousin Douglas just then, and was wearing one of his piston rings on my handle-bar.

Somehow neither of us noticed a very faint light round a bend, and if we had we could not have stopped. Never a sound reached us, for nobody made a sound, and we swept round the bend doing a good thirty.

Pip wouldn't go on the wrong side of the road for worlds. I can stake my mag. on that. But when we did get round the bend we found a nasty old farmer's cart drawn right across the road.

I heard afterwards that Giles had been into Salbershot, and was asleep in the bottom of the cart; one gets very good beer in Salbershot. What?

We made an awful crash!!!

I heard Pip shout something, but whether it was "Flossie," or "Mother," or merely "Damn," I can't tell.

Then I think I fainted. But I distinctly remember winding my front wheel round a large cart horse's hind leg, and feeling him breathing on me!

I woke up next morning very stiff indeed and sore. I was leaning up against a cottage wall, with red rambler roses nodding round and carressing my poor damaged head, and nobody seemed very interested in me.

Somewhere, about midday I think it was, I smelt the faint aroma of the greasy things that rejoice the hearts and appetites of human people at noon.

Surely that was Pip's voice I heard through a window above me, rather washed out and quavery, but still my master's voice. (Please he's *not* a gramophone!)

I could only hear bits, so you'll have to excuse blanks!

M.M.V.: " . . . . For you!"

A Silvery Soprano: " . . . . I adore Cailler's. . . . too perfectly sweet. . . . ."

Suddenly I heard a "Toot-toot" from the road, which I recognised as being the voice of one of the Crossleys in our family, and a corporal appeared. A sandy-haired corporal, along with "several of my Ak Emma friends, who gathered all round me and looked upon me with very long faces.

"Damn!" said the Corporal several times before he went inside.

S.S.: "He's in here. Yes. . . . terrible. . . . ankle . . . . three or four days . . . . *love* having him . . . . Do have a choc . . . . Cailler's, rather nice . . . . Yes . . . . knew him years ago . . . . Eastbourne . . . . sight of him . . . . topping . . . . Yes. What? Sweet little brooch . . . . Yes . . . . lots of R.F.C. people . . . . Yes, quite new . . . . fetch them in to have some tea."

Then she came out. You probably guessed that the silvery soprano was owned by a "she"? And she was fairly pretty, too, as women go—the yellow, fluffy-haired type, for which I have no use. They don't know an armature from a big end!

She started talking to the Ak Emmas at the tender. Then I heard some more conversation.

M.M.V.: " . . . . Devil's own luck. . . . Court of Inquiry. . . ."

Corporal's Voice: " . . . . Damages. . . . Yes. What about the mauve letter lady?"

M.M.V.: " . . . . in the same street . . . . topping little . . . . chums, you know."

C.V.: " . . . . Blank blank cheek . . . my chocolates . . . . say to my little girl . . . . mine . . . . Blank blank . . . ."

M.M.V.: " . . . . uating circumstances . . . . owe you ten bob for it . . . ."

I'm lying in a shed now feeling perfectly dud. All alone except for a sister Pip Emma that the colonel's car chewed up last week, and the remains of a Ford that a Rumpety landed on.

A-courting.

It's beastly not seeing cousin Douglas, but I hear him sometimes. I'd know his bark anywhere. He belongs to a thing they call a "Pilot," and he is very well fed!

I'm s'posed to be waiting for a court of inquiry, and flight sergeants and transport officers and things come and check me every now and then, and lots of nasty humans come in in scores to stare.

On Sunday afternoon the yellow fluffy-haired girl came in with Pip to stare at me, with her grip through Pip's handle-bar.

She was got up in something blue and white, and I managed to get a lovely jealous smear of grease on to it when she stroked my tank and called me a "Dear blessed old bike."

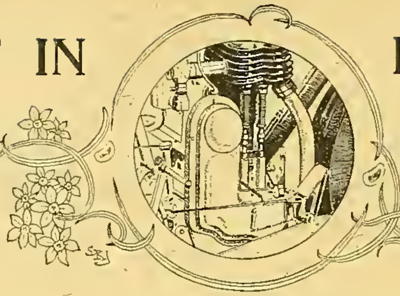
We crashed four months ago, and Pip was still limping on one wheel (they are *some* time about sending me back to Fairborough), otherwise he was looking frightfully cheery and swollen-headed. The fluffy girl had some sort of a brass or copper washer round her third finger on her left handle.

The other bike and I thought it expedient to look the other way and talk about erstwhile mauve letters and carbo-hydrates and explosive mixtures and things as Pip folded his handle-bars round her—our shed wasn't very public.

But we couldn't help hearing several backfires.

SOPHIE C. ELIOTT LYNN.

JUDGMENT IN LUBRICATION.

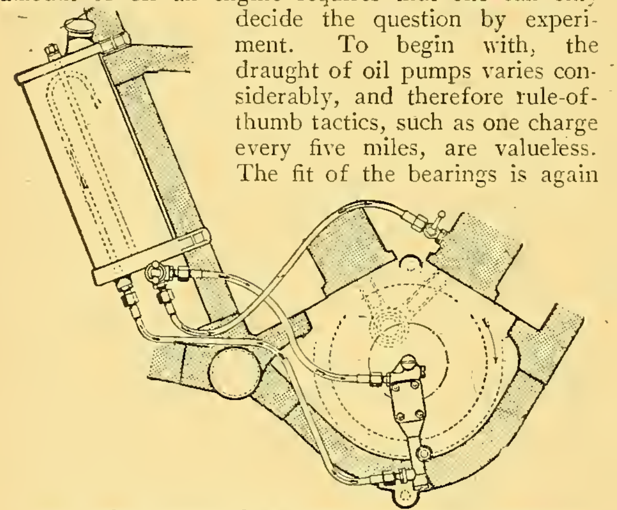


Advocating Mechanical Feed with Visible Drip and Tank Adjustment.

IS there one rider in a thousand who can truthfully claim such intimate knowledge as to the requirements of his engine that he never over-oils? One meets plenty of expert riders who talk learnedly about the importance of oiling "just-so," but how many of them are as infallible as they would make believe in manipulating present-day oiling apparatus? Personally, I acknowledge the fact that on mounting a strange machine I am hopelessly at sea for the first 100 miles or so, and am usually guilty under such circumstances of considerably over-oiling.

Deciding Factors.

So many factors are at work to determine the amount of oil an engine requires that one can only decide the question by experiment. To begin with, the draught of oil pumps varies considerably, and therefore rule-of-thumb tactics, such as one charge every five miles, are valueless. The fit of the bearings is again an all-important factor; for instance, an engine brand-new from the works may require a charge every mile or so, whereas the same engine after 1,000 miles running will demand only the same quantity every eight miles over similar going. The quality of the oil is almost as important; with one brand of oil I used one charge was necessary about every nine or ten miles, whereas with the ordinary quality stuff, purchased at garages, the same quantity would be quite used up in four or five miles.



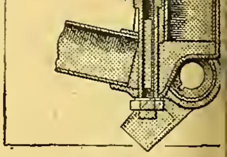
The Enfield mechanical oil system of lubrication, showing the path of the oil during its circulation.

Tackling a Strange Mount.

In mounting a strange machine the following is a pretty safe mode of procedure. Start up the engine and allow it to run warm, and slowly administer oil till smoking begins. You then have a fairly safe foundation on which to work. Run, say, thirty miles, giving two charges *en route*, and at the end of th distance see how many charges it takes to bring tl engine to smoking point again. This ascertained, yo have a pretty fair idea as to the miles per charg and as time goes on you are able to judge as to ho far you can cut down the supply.

Most engines instantly give warning, by their absence of silkiness, immediately the oil sinks below its proper level, whereas they give no indication of the fact that they are over-oiled, except by smoking—not always visible from the saddle —till plug troubles begin.

Practically every rider offends in the direction of over-oiling rather than under-oiling. Should a breakage occur he is in mortal terror of being told by the manufacturer that he has been guilty of under-oiling. Such an accusation is a slur on his abilities as a rider and upon his very manhood. Therefore he wastes oil galore, suffers the inconveniences of an oily engine, compels himself t decarbonise more often than should be necessary, an probably endures plug troubles into the bargain. Aft six months the exterior of his engine is in a filth state, the high-tension wires adjacent to the magnet are saturated, and he has ruined two pairs of boots.



The system of automatic oiling used on the Scott motor cycle.

My advice is—do not be bullied into it! Find out the minimum of oil your engine requires, and do not indulge in constant flooding. When after eight months' riding a timing pinion strips or the tank comes loose, and the manufacturer wants to make out that under-oiling is the cause, ask him why, in the name of all that is wonderful, he does not make a proper engineering job of his machine and introduce some spirit of progress by employing mechanical lubrication—like the Americans! That will dry him up.

The Triumph system of lubrication is a simple hand pump. Several other eminent makers still pin their faith to this method of oiling.

The one fault with all mechanical lubrication systems of to-day is that the feed is not visible. It would be very desirable, I admit, to have an oil pump contained

Judgment in Lubrication.—

in the sump, with no external fittings or pipes whatever, yet the necessity for a visible drip is a very real one. Without such it is difficult to acquire proper confidence in the system, and in cold weather you never quite know where you are. If the pump were contained in the sump, and there were no external fittings through which oil was to be forced, then the draught of the pump would not be so much affected by the temperature of the atmosphere, but still the sight feed would be a useful check. Say, for instance, that one is riding in very hilly country. On very long descents it is necessary to shut off the oil completely, while on the succeeding ascent a double supply is required. How very much more convenient it would be to make these adjustments by means of a turn needle in the tank than to have to get off and readjust the pump!

The Harley-Davidson mechanical oil pump. There are no check or other valves.

Whatever the system, hand adjustment is necessary. The throttle-controlled pump comes very near perfection, but it makes no allowances for the varying viscosities of the oil used. This can only be done by means of hand adjustment, the drip being set to feed a minimum supply, and an emergency hand pump used in addition.

It may be claimed that the drip has not proved satisfactory—a claim with which I heartily agree. The rate at which the oil passes depends on the position of the plunger when the adjustment is made. If the rate of drip be about right with the spring fully compressed—*i.e.*, the pump at the bottom—the oil will hardly drip at all when the spring is relaxed by the plunger rising. The whole system, so far as a fixed setting is concerned, is utterly hopeless, and most riders simply unscrew the needle and use the pump as a direct hand pump. With mechanical feed, however, administering a constant pressure, one could really set the drip to pass a correct supply, in just the same way as if it were invisible, and a full charge of the hand pump when conditions demanded would see one through. Thus the visible drip, while affording a real convenience imparting confidence, would not detract in any way from the present efficiency of the system.

Crank Case Suction.

Though I am aware that many riders do not at all like those automatic systems dependent on crank case suction, I, personally, consider them infinitely superior to the ordinary spring-loaded plunger. The adjustment, at any rate, can be fixed to feed a constant supply, and need not be upset in order to administer an overdose. The trouble with them is that the rate of flow is so considerably determined by the viscosity of the oil used—a state of affairs which would apply much less if the oil were positively driven by a mechanical pump.

The main object of these meditations is to illustrate the fact that, whatever the future may reveal in the way of oiling systems, some judgment will still be required of the rider in the way of adjusting the supply. Personally, I favour the idea of mechanical lubrication with instantaneous hand adjustment and supplemented by hand pump. It is a mistake for manufacturers to aim at an oil feed that will require no adjustment whatever except under very exceptional circumstances. From what experience I have had of such systems they are not satisfactory, and require more adjustment than their designers ever calculated. If, then, we are to have hand adjustment, let us have it accessibly and visibly placed, and including a sight feed, which is invaluable in assisting one's judgment. Judgment is essential but not infallible, and it makes a suitable partner for the mechanical method. CHINOOK.

"NOTHING TO BUY BUT THE LICENCE."

A Plea for the Completely Fitted Motor Cycle.

THE above is the title of a recent editorial comment in *The Autocar* dated March 30th. The point of the remark is, of course, that car manufacturers should turn out their cars after the war absolutely fully equipped, so that the purchaser will not be compelled for some time after the purchase to be continually buying small extras that could quite well have been incorporated with the car.

The same doctrine can certainly be applied to motor cycles. The fitting of reliable and well-made accessories at the present time is a job that often taxes the powers of the novice both with regard to the choice of the accessories in the first instance, and their actual fitting in a really secure and reliable manner afterwards. Also there is the annoyance of the discovery that after having paid £70 for a motor cycle one must put one's hand in one's pocket again to the tune of some ten pounds for lamps, horn, etc., before one can venture on the road. If the machine is to be fully equipped the expense will probably exceed £10, covering, as it will, a first-class lamp set, mechanical horn, and a reliable speedometer. If it is a sidecar outfit and the owner is ambitious, a dynamo lighting set will be essential, and added to the actual cost of the set and that of fitting, there is the item of time lost in the use of the machine while the accessories are fitted. The makers could fit these accessories in much less time, and consequently the owner would not have to surrender the use of the machine for a time shortly after having purchased it. Consequently, we think manufacturers would do well to give serious consideration to the question of turning out their machines completely equipped ready for the road. If they see any objection to this policy as applied to every machine that leaves their works, perhaps they could list a machine really ready for the road as well as their ordinary models sold short of lamps, horns, and such vital accessories.

Neglect.

Judging from the rattle of many motor cycles now used "on work of national importance," their owners or drivers do not give their machines the same attention as the average pre-war motorist used to give to his mount, however decrepit it might have been.

Sidecar Ambulances.

These are doing well with the French Army in the Vosges district, cars having had to be abandoned, owing to the rough country. A previous member of our staff, C. F. Haywood, now in the R.N.A.S., was driving one of these cars.

Morocco.

The Acting British Consul at Casablanca, in reporting on the trade of Morocco, states that the prospects for business in motor cycles and accessories deserve the special attention of British manufacturers.

Cornering at Forty Miles an Hour!

Ex-Cpl. Eric Williams, D.C.M., of T.T. fame, has just added to his varied experiences of life that of being a witness in a civil action. At Hereford County Court, before Judge Tobin, K.C., two motor cyclists, father and son, farmers in Herefordshire, sued a Hereford milkman for £35 damages for personal injuries and repairs to a sidecar outfit, the defendant putting in a counterclaim for £24 damages to his milk float. The motor cyclists met the milk float on a blind corner in the city in October last, and there was a bad smash. The case turned on the question of speed. The motorists swore they were only going from eight to ten miles an hour, but prominent citizens who came on the scene gave evidence of road scars in the track of the motor cycle for a distance of thirty-two feet. It was on this point that the T.T. holder's opinion was very useful to the Court. Mr. Williams, who since being discharged from the Army has been, and is now, in charge of a tractor ploughing unit in Herefordshire, expressed the expert opinion that the motorists must have been going thirty miles an hour. He also had one or two interesting things to say on motor cycling. For instance, he said an expert motor cyclist could with a twin-cylinder combination outfit take a right-angle corner safely at twenty miles an hour; he had done it at forty! The Judge adopted Mr. Williams's view of the case, and, attributing the smash-up to the excessive speed of the motorists, dismissed their claim, and awarded defendant a verdict with £18 damages and costs. An unusual feature in the case was that the milkman was insured against accidents and the motor cyclists were not. By a coincidence, the accident happened within a hundred yards of the spot where a brother of the younger plaintiff was killed while motor cycling two years ago.

Glad of the Petrol Restrictions.

We have discovered him at last—the fatuous optimist who can see good in the petrol restrictions. He is a neighbour of ours—that is, a neighbour of position, not of sentiment—and came in to see us after a fifty-mile business journey on his motor cycle. He said, "I am glad there are restrictions, I am glad we cannot ride as we used, I am glad we cannot watch young men aspiring at 100 m.p.h., I am glad there is no likelihood of violent sea-sickness in getting to see a motor cycle race. If all these things were as of yore the garage proprietor and small repairer would soon be all millionaires and more independent than ever, because yellow gold would be pouring into their pockets all day long—and every day, too—in payment for repairs to broken frames as a result of the condition of war-time roads. I can hardly sit down after having travelled fifty miles; but 200 miles used to mean nothing to me. Therefore I am glad of the restrictions; and may they endure till our roads are roads once more."

Special Features.

THE DOUBLE-ACTING ENGINE.

HORIZONTAL COUPLE.

Activity on the Metropolitan (Police) Front.

During the week-end we saw numerous cars standing outside the prominent London hotels, such as the Berkeley and Ritz, and the drivers were being interrogated by the police; while a police trap was working in St. James's Park at mid-day, and we saw a motor cycle and sidecar stopped. It is clear that the police are making stringent enquiries as to the use of motor vehicles in the Metropolitan area, and those who are using petrol unlawfully will doubtless be made to suffer heavy penalties.

Unanswered Query.

If the gentleman from Stevenage wh wants some information and help *re* New Hudson twin motor cycle wil address his query in a proper manne and will observe the rules printed ever week on our Questions and Replies page we will try to help him. Our only clu to the whereabouts of the enquirer is th postmark on the envelope of his lette and we are rather afraid that a lette from us addressed to "Constan Reader," Stevenage, might fail to reac its destination.

The Walking Encyclopædia Again.

We were recently asked a question th answer of which involved a knowledge practically all there is to be known abou bomb dropping from aeroplanes.

All that we ever undertook to do wa to give our readers help in motor cyclin matters, and this is all we can promi at the present time, though in th particular case we were able to satis the enquirer's thirst for knowledge.

Chinook" on Active Service.

Our contributor "Chinook" is in rance, driving a sidecar ambulance.

ockefeller's War Bonus.

A war bonus of £600,000 is being given y the Standard Oil Co. to its employees.

iction in Motor Cycling Paper.

Our American contemporary, *Motor ycle and Bicycle Illustrated*, is now inning a serial which promises to be s exciting (!) as any of the "To be ontinued" film stories.

ight Cars for the Army.

A special squadron of about one dozen wner-drivers of light cars, which must ot be of American manufacture, are equired by the Middlesex Motor Volunteers, Southern Group, for important ork. Those possessing such vehicles, ho are willing to serve, should apply Capt. A. Horsfield, Messrs. Selfridges, lotor Department, Oxford Street, London, W.1.

oes the Petrol Controller really exist?

He does, and his address is 19, erkeley Street, London, W.1. Will all hose readers who have read *The Motor ycle* since its first number, and have ever missed an issue or a page, please ote? We are still receiving in fair umbers every day the query, "Can you ell me to whom I should apply for a ermit to buy petrol?"

ritish Quality.

According to the opinion of a driver the A.S.C., M.T., who has driven verything from a 3 ton lorry to a two troke lightweight, the English motor ycle undoubtedly stands supreme in the ests to which it has been subjected. he American machines, he says, have stablished a reputation for reliable unning which they have not justified nder war conditions.

conomy?

A West of England motor cyclist recently smashed up his big twin engine by dopting a policy of false economy. A riend employed at a sawmill sold him a uantity of "special" lubricating oil at low price, and after running a little ime on this oil the big end seized and recked the engine. It afterwards transired that the "special" oil was ibricant which had been used in a as engine, and not only had it been obbed of its lubricating qualities, but as well mixed with fine sawdust. Once iore, we reiterate there is no economy cheap and poor quality lubricants.

verseas Trade.

A Canadian soldier who is in an nglish convalescent camp writes: "If ome scheme such as you mention in your rticle, 'Overseas Trade Development,' the issue of March 14th, could be tarted, it would be a revelation. In ancouver, B.C., there are not more than wenty-five or thirty English motor ycles, while there are hundreds of ndians, Harley-Davidsons, Hendersons, eerless, etc. I am quite convinced that here would be really a big trade in anada for light, reliable machines, if hey could only be purchased at a easonable price."

Motor Cycling Police.

Almost every town of any size in the United States has its motor cyclist policemen.

Synthetic Rubber.

A company has been formed in Sydney, N.S.W., with a capital of £30,000, to acquire inventors' rights in a new compound intended to replace rubber.

Police and Motor Cyclists.

Police have been stopping all civilian motor cyclists, including riders of sidecarriers that work in the Woolwich, Greenwich, and Eltham districts. Two members of the Woolwich club—holding special permits—were held up and licences, etc., demanded.

The Industrial Reconstruction Council.

Mr. Otto Thomas has been elected a member of the Executive Committee of the Industrial Reconstruction Council, and hopes to be of service to motor cycle manufacturers in that capacity. He will be glad to hear from any manufacturer who would like to know more of the work of the Council. Address c/o *The Motor Cycle*, 20, Tudor Street, E.C.4.

Motor Cycle Engineers' New Posts.

Certain motor cycle engineers in the S.E. London district, who received recent notices terminating their engagements, have now accepted engagements at a certain new aeroplane factory in the London district, where skilled engineers are urgently wanted. The transfer from munitions was effected through the engineers' advisory officials, and their motor cycle experience should prove of service to the workers.

Rumanian Oil.

Reports from German sources state that Rumanian oil supplies are much less than last year.

Police Trap.

We are informed that a police trap is in evidence near the Swan Inn on the road over Clapton Common, N.

Japan.

Traders in Japan are sending out enquiries for motor cycles and sidecars, for which there are great possibilities in that country, owing to the narrow roads, which are unsuitable for large cars.

More Matchless Solos for Italy.

On Wednesday last week a horsed lorry was seen outside Woolwich Railway Station, with a number of new Matchless solos in light crates and stencil lettered, "Matchless Motor Cycles for Italy." Judging by the light, open crates, they were consigned by the overland route, *viâ* a certain French port.

A Harley Mystery.

Who is the driver of a Harley sidecarrier outfit to be seen daily in South London who wears a civvy pre-war Brooklands outfit and a silver badge? His identity is concealed by a brown leather helmet and goggles. A policeman at a point crossing held up the traffic on his approach, and gravely saluted the rider, who returned it. What are the contents of the sidecarrier? Who is the rider? A former famous despatch rider's name is mentioned. He is attracting attention at places as far as Woolwich and Bromley, besides the City and West End, and his skill in handling the mount is commented upon.

An instance where a sidecar outfit is utilised to its limit of usefulness. Mr. Cecil Hartshorn, who sends us the photograph, says the Norton stands up to the work splendidly.

SIXTY MILES A DAY.

GNR. L. ALLEN, of the M.M.G.S., sends us a photograph of his Douglas, together with a chatty letter. He says: "The old 'bus has been going strongly for the last eight months, doing on an average sixty miles a day. I think this is rather a record, especially considering it has not been in dock. I went to France early in 1915 with the 4th Battery, and was in the Hill 60 stunt, where we figured pretty well. With the best of luck to *The Motor Cycle*."

Gunner Leonard Allen, M.M.G.S.

D.R.'s IN THE CAMBRAI STRUGGLE.

CPL. A. W. BYERS, who is a member of the Sunderland and N.E.A.A. clubs, says in a newsy letter that he went through exciting times during the great struggle at Cambrai. He says he met several men who were associated with the motor cycle world before the war. Among them were Frank Beyley (Enfield), Fred Turvey (B.S.A.), Hal Hill (Zenith), and Serrett (Triumph). All were fit and smiling when he last saw them, and eagerly looking forward to future days of keen and friendly competition.

* * *

THE MOTOR MACHINE GUN.

IN the recent fighting the Canadian motor machine guns played a splendidly gallant and useful part. This is the first time that mobile machine guns have been able to be used for a long time, and, of course, it is due to the fact that we are now engaged in a war of movement. Their use proved, in the words of a Brigadier-General that "cavalry against organised machine guns with Canadians firing them is useless." At one point where the Canadian infantry were in difficulties a motor cyclist private was sent to fetch up the armoured cars, and, he having got through successfully, they came to the rescue and beat off the enemy. Thanks to his prompt assistance, cars, some Tanks, heavy artillery, and infantry were able to extricate themselves from a very dangerous position.

* * *

MILITARY CROSS AWARDS.

A GLANCE through the list of officers who have recently received the Military Cross shows that two of the awards go to lieutenants of the A.S.C., M.T.

Lt. L. T. Maplestone, A.S.C., received the award for conspicuous gallantry and devotion to duty when in charge of lorries dumping ammunition. The dump was heavily shelled all day, and he remained at his post, though wounded, directing operations and getting all the lorries away safely. By his courage and coolness he set a fine example to all who came in contact with him.

Temp.-Lt. P. W. Vernon, A.S.C., gained the distinction for conspicuous gallantry and devotion to duty when in charge of two caterpillars with guns for his battery. Seeing one of the cartridge dumps on fire, he and his men immediately went and extinguished it, without other assistance in any way, thus saving the majority of 2,000 cartridges.

NO MEDAL FOR GALLIPOLI OPERATIONS.

NO Imperial Medal and no speci Star are to be issued for tl Gallipoli operations.

* * *

GROUP ENLISTMENT FOR ME OVER AGE.

MEN over military age up to 50, wl volunteer for home service in tl Royal Garrison Artillery, may e list in groups of ten to twenty. Ea group will be posted to a unit for coa defence as near their homes as possibl and the men will be given a guarant that they will be kept in that unit.

* * *

SAVING A TANK.

WE have just heard that Stanley Cy Hunt, who two years ago enlist in the M.M.G.S., has been pr sented with the M.M. and certificate l the Brigadier-General for conspicuo bravery and devotion to duty at Ypr and Cambrai. He brought an abandon Tank safely back to our lines singl handed under heavy shell fire.

Pte. Stanley C. Hunt, who brought an abandoned Tank back to our lines single-handed

THE MOTOR CYCLE AVIATION SECTION

The enormous importance of the Air Service needs no emphasis: it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouraging of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

How to Join the R.A.F.

details were published in *The Cycle* for March 21st. The earliest which a candidate can be admitted officers' cadet wing is seventeen and ten months.

◇

200 Miles in 2h. 38m.

American airmen, Maj. Ryan and Frost, have flown from Foggia to , a distance of approximately 200 in 2h. 38m., with one stop at s.

◇

nquisher of Fifty-four Aeroplanes.

t. J. C. McCudden, V.C., D.S.O. bar), M.C. (and bar), M.M., and de Guerre, has accounted for fifty- enemy aeroplanes. His brother, Lt. McCudden, M.C. (who is reported g), is credited with having brought eleven enemy machines.

◇

British Aircraft Industry.

iteh-ad Aircraft, Ltd., has obtained sanction of the Treasury to issue l up to £1,000,000, and has recently d the public to subscribe to an issue 450,000 in ordinary shares as part above.

◇

The Private Aeroplane.

possibilities of the "private" lane as a commercial proposition are nised by at least one large aeroplane rn, which has designed and built a solo machine which, it is said, takes ery little more room than a car, and cost no more than the average car e-war days. It is fitted with a com- ively low-powered flat twin engine maker well known to the readers of *Motor Cycle.*

Articles on Flying.

Under the title "Flying Facts and Theories" the following articles on aviation, by W. G. Aston, A.M.I.A.E., have appeared during the last six months:

1917.
Oct. 11th.—"Relative Motion."
„ 18th.—"Mono-, Bi-, or Tri-plane?"
„ 25th.—"Pusher or Tractor?"
Nov. 8th.—"Air or Water-cooled?"
„ 15th.—"Relative Motion and Momentum."
„ 22nd.—"Some Points about Screws."
Dec. 6th.—"The Radial Engine."
„ 20th.—"Some Further Points about Screws."
1918.
Jan. 3rd.—"More About Turning."
„ 10th.—"The Influence of Altitude."
„ 24th.—"The Feel of the Machine."
Feb. 7th.—"A Reply to Further Criticism."
„ 21st.—"The Inconstant Wind."
„ 28th.—"Gusts and Their Effects."
Mar. 21st.—"More About Gusts."

During the same period articles on aeroplane engines were published.

1917.
Nov. 29th.—"About Aero Engines."
Dec. 13th.—"The Rotary Type."
„ 27th.—"The Radial Type."
1918.
Jan. 17th.—"The 260 h.p. German Mercédès Aero Engine."

THE VICTOR AND HIS VICTIM.
A British pilot seated in a Boche Albatross, which he had forced to land in our lines.

Flying in N. Africa.

Three French aeroplanes flying in Algeria recently covered 469 miles in 7h. 22m.

◇

German Imitation.

The Germans are imitating types of British engines which we made some time ago, but have since vastly improved.

◇

An Aerial Postal Service.

The Times states that an aerial postal service between Petrograd, Moscow, and the Crimea, and between Petrograd and Sweden, will be introduced in the near future.

◇

Public Schools and the Air Service.

King Edward's School, Birmingham, claims to have a higher percentage of its old boys in the Royal Air Force than has any other school.

◇

Henry Farman.

Henry Farman made the first circular flight (1,093 yards) in Europe at Issy, France, on January 13th, 1908. On May 30th of the same year he flew 1,360 yards with a passenger, the first public passenger flight. Five months later he made the first cross-country flight from Châlons to Rheims—16½ miles.

◇

Aeroplanes for the Transport of Wounded.

Experiments have recently been made by the French authorities as to the suitability of aeroplanes for transporting wounded from the front line dressing stations to the base hospitals. These aeroplane ambulances can travel at a speed of eighty miles an hour, and while in flight are free from the shocks usually experienced by road ambulances.

STUNT FLYING.

I.—ITS NECESSITY. By "Torque."

The following is the first of a series of articles which will deal with trick flying in most of its aspects, concluding with diagrams illustrating the principal stunts and the methods of performing them.

THE term "stunting" has almost risen to the dignity of classical English, and is, of course, the pilot's term for trick flying. During the last ten years the various manœuvres now known as "stunts" have undergone weird transformations. They were originally performed quite unintentionally, and resulted in the death of the stunter. They are now performed deliberately, either to save the life of the pilot or to slay somebody else. By way of preface, it is advisable to explain why the fighting pilot must be a first-class stunter. This necessity hinges round two facts. The first is that there are no trenches or dug-outs in the air, nor indeed any other type of genuine hiding place, excepting clouds. Clouds are extremely tiresome objects. They appear in vast numbers and great density when you are bombing on a moonless night, and particularly pray for a clear sky. But if your gun has jammed, and umpteen members of the Richthofen travelling circus are diving on to you, the nearest friendly cloud is usually about two hundred miles away. Consequently, when a fighting pilot is outnumbered or taken by surprise, or his ammunition belt is used up, or his guns have jammed, the air usually offers him no cover, and his one hope of escape is to offer his foe an impossible target. Consequently he stunts like mad. He makes his aeroplane gyrate like a tipsy leopard with a fire cracker hitched to its tail.

Marksmanship in the Air.

Marksmanship in the air never approaches the certainty normal on ground ranges. A gun mounted on a platform (to wit, the nose of an aeroplane) travelling at 130 m.p.h. cannot be expected to produce Buffalo Bill shooting, even at a stationary target: but when its target is a stunting aeroplane—*i.e.*, an object executing incalculable frisks in lightning whorls—the chance of a hit becomes even more remote. Cynics liken the machine gun to a blunderbuss. Disgruntled rifle merchants remark that they could hit anything if they could pump out lead at the rate of 500 bullets per minute: but it must be remembered that a "group" of 20ft. in diameter at 100 yards range is not bad shooting for a Vickers in the air, and you may often put fifty shots into a 20ft. ring without hitting the enemy pilot or his tanks, or, indeed, without grazing his tailplane. Moreover, the fighting scouts seldom carry swivel guns. The guns are rigidly fixed to the aeroplane, and are aimed by pointing the aeroplane bodily at its target. Consequently a series of crazy stunts sets the opposing gunner an awkward task.

The Pilot's "Funk-hole."

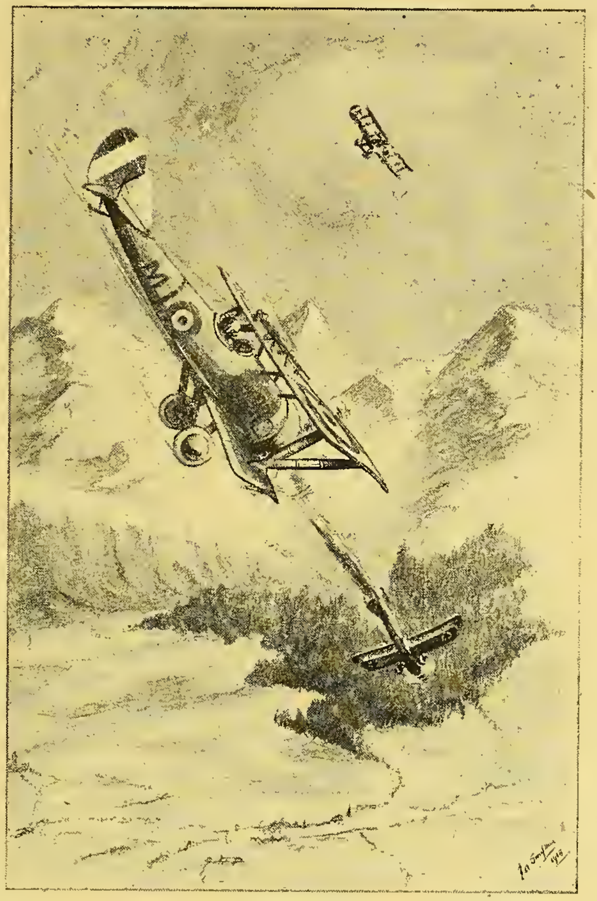
Stunt flying is unquestionably the pilot's "funk hole." Nor is it in any sense a libel to assert tha the fighting pilot needs a funk-hole, for if surprises on sea and land are the commonplaces of warfare, a surprise in aerial fighting is infinitely simpler to effect and infinitely more dangerous. The pilot's view i restricted by many factors. If he be flying a rotary the windscreen in front of him may be smothered wit oil. He may get a fly in his eye. He may be devoting his spare attention to freeing a gun stoppage, or tinkering with his oil gauge, or reading an instrument. In any case, his eyes are limited to quite a small pane of the horizon. When you are controlling a projectil moving through space at more than double the spee of the Scotch express, you do not enjoy many opportunities of looking behind or around. Below you, th lower plane blots out a great deal of what lies immediately beneath. Upper planes are variously disposed Sometimes they frankly and unashamedly cut off th overhead view as thoroughly as the roof of a railwa carriage. Sometimes they possess so-called "transparent panels," which on occasions are no more transparent than goggles in a snowstorm, or the glass of

Stunt Flying.—

motor bicycle sight-feed lubricator. Sometimes the upper plane is at such a level that its trailing edge decapitates you very neatly in a landing crash: it may be your own fault that your body is not a stock size, but the painful result is that you divide your time between looking over and under that infernal plane. Your ears are no help to you. An engine, bigger and noisier than ever graced a racing car, is bellowing furiously just under your nose, and the last thing that you desire is that it should sigh into silence. A yard or two to the front the propeller is threshing like a power saw in a Canadian lumber mill. You can see little, and hear less. Fritz quite understands the possibilities of waiting upstairs in a cloud, and diving on to you unbeknownst from astern. He is also aware that if you are driving towards a dazzling sun there are chances of a furtive approach from many points. You may be the bravest and most alert pilot in the two hemispheres and yet fancy you are alone in the empyrean until a staggering blow on your shoulder or a weird whistle past your nose, or the streak of a flaming bullet, or a chunk of wood flying from a splintered strut, or a bracing wire suddenly flapping loose, tells you that a Boche is sitting on your tail, spitting death at you. If you let him hold his aim a fiftieth of a second longer, you may sign your own death warrant, wherefore you stunt like the very dickens in self-defence.

Defence soon merges into the offensive. As you stunt, your brain, strung by the cold smack of frightful peril, suddenly informs you that Fritz—whom you can now see in the intervals of looping and rolling and side-slipping—is about to do so-and-so: and, further, that if you retort by doing so-and-so, the next pulse beat will set you on his tail. For an instant he will be the blind man instead of you: his forward pointing guns will be out of action, as yours were just now, when he loosed off at you. You try the dodge: and if your brain and muscles possess that split-second, forked lightning kind of co-ordination without which no scout-pilot can survive for two days at the Front, you may "crash" him.

Stunt-flying thus has affinities with both defensive and offensive fighting. In this respect it resembles what ground fighters know by the name of "cover," and is an essential part of tactics. It may further be compared to the "feint," since you can use it to deceive a watchful adversary as to your own intentions, whether in advance or retreat. It includes the counter-attack, of which the case cited above is a good example. It is so vital to aerial fighting that pilots still quarrel as to whether stunting is less or more important than gunnery, speed, and climbing.



AERIAL WARFARE ON THE ITALIAN FRONT.
A fast Nieuport fighting patrol is successful in an encounter with an Albatross and sends it down, crashing to earth, in flames.

THE PROGRESS OF AVIATION.

Some Remarks of a General Introductory Nature on Aeroplanes and Aerial Locomotion.

It is perhaps almost a commonplace to say now that progress in matters aerial has been more rapid than in any other sphere of human activity. What is the very last word to-day may in six months' time be on the wane in popular favour, and in another six months will perhaps be practically obsolete or simply useful as a matter of history and as affording a valuable lesson in the direction that progress and development of the future may be expected to take.

Design in General.

In the earliest days of any type of heavier-than-air machines most of the popular examples were of the biplane type, but there were also many monoplanes, and at one time it was very doubtful which of the two would ultimately emerge triumphant. When war broke out the biplane was certainly in the majority, but the monoplane was by no means defunct, and as late as 1915 monoplanes were quite common—but how many are seen nowadays? And yet the monoplane was always the faster machine, other things being equal, and he would have been regarded as something of a freak who had prophesied that the monoplane was then enjoying the height of a brief prosperity. Questions of stability and engine power and development, however, entered into the matter, and the biplane has now entirely ousted the rival type, and may in time even have to give way to the triplane.

The Progress of Aviation.—

The question of tractor or pusher type is another that by now has been almost as definitely answered, but at one time there were as many adherents to the pusher as there were to the tractor type. And consequent upon this perfection of a type that once seemed the least likely to meet with final approval and acceptance has come another development that formerly would almost certainly have been regarded as impossible of accomplishment. The reference is to the fitting of a machine gun behind the propeller, and the synchronisation of the firing of the gun with the revolutions of the prop so that the bullets may pass through the latter without inflicting injury upon it.

Engines.

Progress in the engine world is the matter that is perhaps most likely to interest motor cyclists as such and not as incipient aviators as so many of them are. Originally engines were as low as 9 or 10 h.p., and were based primarily on motor cycle practice. Nowadays aeroplanes with a total engine power of something in the neighbourhood of 600 h.p. are quite common, and single engines yielding some 475 h.p. are also common, though not yet in use on any other than lighter-than-air machines.

Development has proceeded along certain definite and easily recognised lines. At first motor cycle power units provided the precedent; this was then replaced by a following of motor car practice, and the replacement of the air-cooled by the water-cooled engine. Nowadays there are indications that a return to air-cooled practice is on the *tapis*, but, as already stated, prophecy is a dangerous game. Also some whispers of steam engines for aeroplanes have been heard, coupled with stories of a new wonderfully light steam engine.

Besides the changes from air to water-cooling, and probably the present change back again, there have also been very considerable strides and changes in the actual shape of the engines themselves. While the first engines were of the radial type, having perhaps anything from three to seven cylinders, these have now been supplemented by rotary engines and radials with as many as twenty cylinders. Also the ordinary car shape of six-cylinder single line engine has done very good service, and has been in turn supplemented by the eight- or twelve-cylinder V twin and, later, the eighteen-cylinder broad arrow type.

All these various types have been made and used in both water and air-cooled patterns, with the single exception of the rotary engine, which, of course, is never likely to be made in a water-cooled shape. The earliest efforts consisted of air-cooled types invariably, and the later and more efficient water-cooled rival now shows signs of giving way again to the first in the field. All of which will probably have important bearing on the design of engines for both cars and cycles when these again receive the attention to which they have been accustomed. Paradoxically, progress thus appears likely to retrace its steps along its original path. Just as cycle and car engines led to the evolution of the aero engine, so the latter now seems likely to point the way for further development of the former.

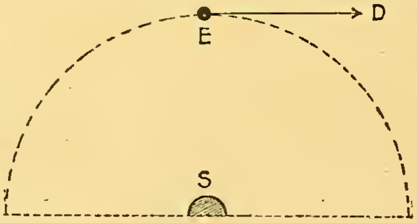
By keeping motor cyclists *au fait* with progress in the aerial world this supplement should prepare them for many interesting possibilities that may be expected in road vehicle spheres after the war—possibilities that may often on the surface appear nearly allied to impossibilities. In conclusion, this brief introduction may be ended with a note of warning—be chary of prophecy, but, if anyone feels inclined to indulge in it, be still more chary of criticism.

CORRESPONDENCE.

The Editor, although accepting no responsibility for the opinions expressed by correspondents, reserves the right to publish a portion of a letter and to omit any part which he does not consider interesting or essential. All communications under a *nom de plume* should be accompanied by the name and address of the writer.

FLYING IN A CURVED PATH.

Sir,—I was interested in "Dyne's" remark with regard to the revolution of the earth round the sun. Now, Newton's first law of motion states that a body continues in its state of rest or of uniform motion in a straight line unless it is compelled by some external force to change that state. This property of matter, in virtue of which it retains its present state of rest or of motion, unless compelled by a force to alter that state, is called inertia.



Let us consider the earth's motion; at any part the earth E is for an instant moving in the direction of the tangent ED, and because of its inertia the earth would continue to move in that direction, were it not for the gravitational pull of the sun S.

For the point under discussion we have only to deal with one force, *i.e.*, the deflecting force which alters the direction and velocity of the earth (the sun's pull), but in the dim distant past some force or forces caused the earth to have motion. It is due to the combination of the earth's motion and the sun's gravitational pull on the earth that our planet describes a curved path round the sun. If the earth's motion ceased, it would fall along ES to the sun; if the sun's attraction ceased, the earth would continue for ever along ED (unless or until acted upon by some force).

C.B.M.

FLYING FACTS AND THEORIES.

Sir,—In Mr. W. G. Aston's article on "The Influence of Altitude" (January 10th) there occur two passages which appear to me to be contradictory.

On page 30, column 1, paragraph 3, Mr. Aston says, "If the power of the engine . . . remained at all altitudes the same as on the ground . . . the speed would be increased in inverse proportion to the density."

Again, on page 31, column 1, he says, "Since resistance is proportional to the square of the aeroplane speed, multiplied by the density, it is obvious that in these conditions (constant power, irrespective of altitude) the speed of the aeroplane at various heights will be inversely proportional to the *square root* of the density."

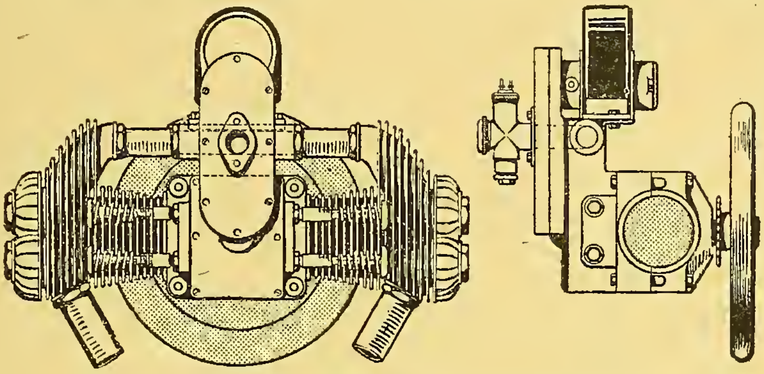
Referring to the power of the engine at various heights, Mr. Aston states that since the density at 20,000 feet is, roughly, 50% of that at ground level, the engine at 20,000 feet will give 50% of its power. Surely this is ignoring the loss in volumetric efficiency due to decreased density. If the pressure under which the charge enters the cylinder is halved it seems reasonable to suppose that the amount entering the cylinder will be halved also, so that the power will be *one-quarter* of that at ground level.

I am quite prepared to discover that Mr. Aston is right, as usual, and that I am at fault. I have derived so much benefit from Mr. Aston's articles that I hope he will see his way to enlighten me on these points. C.E.F.

A RALEIGH FOUR-SPEED FLAT TWIN?

A Probable Post-war Motor Cycle by a Famous Cycle Firm.

COMING events are forecasted in the patent files, and, while thousands of inventions are patented and then forgotten, when a large concern such s the Raleigh Cycle Co., Ltd., patents designs for at twin engines and four-speed gear boxes one may educe that this firm interested in motor ycles. There is no oubt that a motor ycle by the famous ottingham concern ill create a great eal of attention oth in the trade nd among riders enerally, and one ay say that the re-ntry of a Raleigh nto the world of otor cycles would e welcomed, especi-lly at a time when appears that several makes, more or less well known efore the war, may be absent when the peace models ome to be scheduled in a buyers' guide.



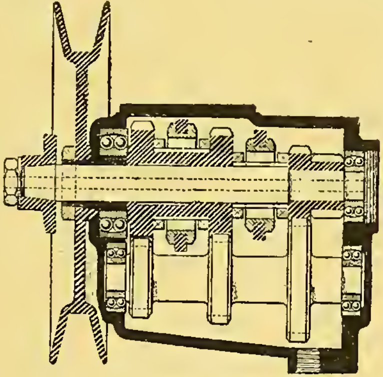
A flat twin engine recently patented by the Raleigh Cycle Co

General Engine Arrangements.

The patent specifications do not include particulars oncerning bore and stroke, nor de-ails of the complete machine, if such ave yet been decided upon. We have erely the bare outlines of the ngine. The chief point of the atent engine is the arrangement of e parts so that an open space is rovided between the crank case and e magneto platform, to allow free ccess of air to the back cylinder. he timing gear case is arranged on ne of the side faces of the crank ase, a bracket being provided to arry the magneto, which overhangs e crank case.

The drawing accompanying the pecification reveals other interesting details, but hether this illustration is intended merely to be iagrammatic is not clear. It will be seen, however, that the carburetter is shown as being fixed to a flange on the timing cover, while the centre piece of the induction pipe is presumably part of the crank case casting. This would make a very clean job of a part of the flat twin often open to improvement.

The second patent relates to a four-speed countershaft gear box, which, incidentally, does not appear to embody a clutch. The drawing in the specification, reproduced here, shows a very neat and apparently simple design. The main shaft driven by the engine carries on one end a sleeve, to which is connected the driving pulley. A layshaft carries three pinions meshing with three others, two of which are rotatably mounted on the main shaft proper and the other on the sleeve. Slidably mounted on the sleeve is a dog clutch adapted to clutch either the sleeve pinion or the adjacent shaft pinion to the sleeve. A second dog clutch is slidably mounted on the shaft, and connects either of the shaft pinions to the shaft. By manipulating these clutches four separate speeds can be obtained with very little more mechanism than that of the more conventional three-speed box.



The Raleigh four-speed gear box.

The Future.

We hope to be able to give more details of this interesting proposition at a later date. In the meantime the motor cycling world will know that if a Raleigh motor cycle fructifies it will in every way uphold the reputation the Raleigh Company has won in the pedal cycle field. It is certainly a point of interest that an entirely new model such as this will be on the lines of the flat twin and four-speeds.

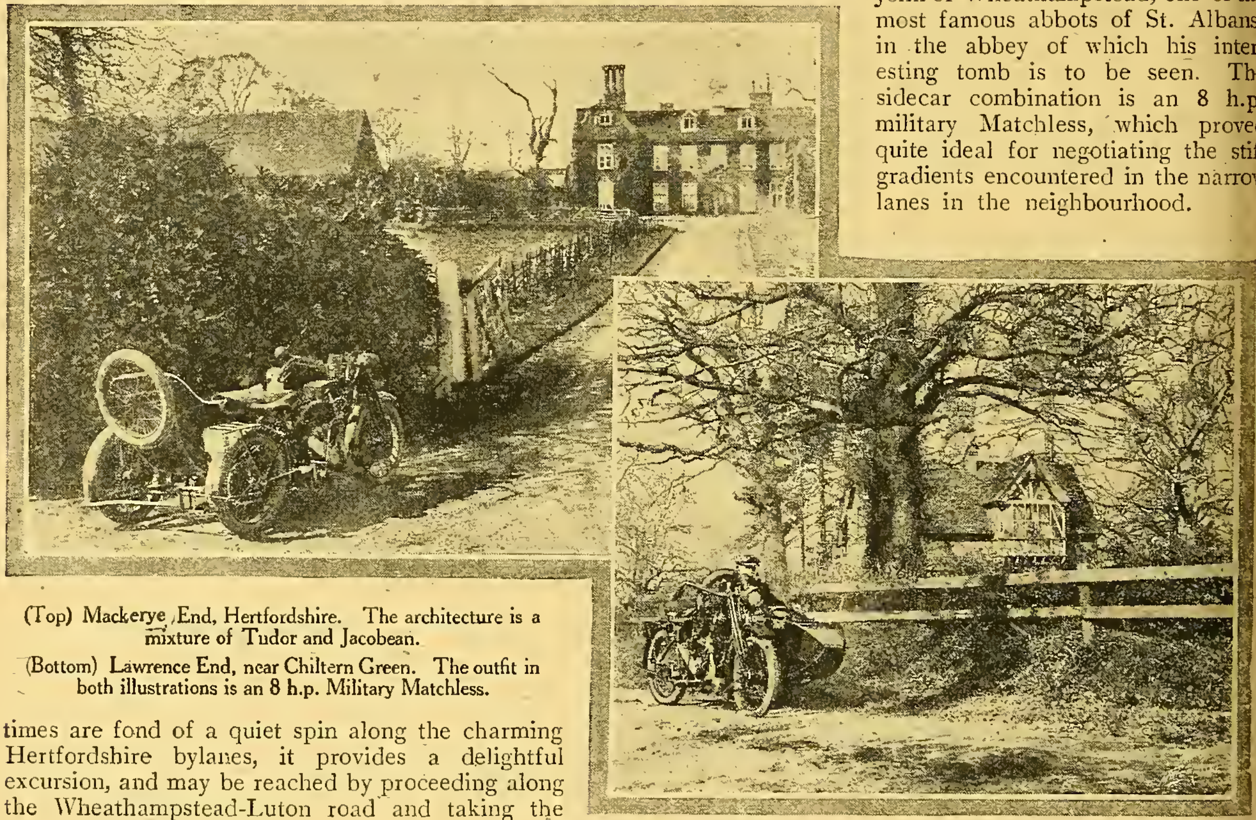
CONTROLS AND ONE-ARMED DRIVERS.

THE designing of a control system for a motor bicycle intended for one-armed drivers presents no difficulties at all, and the problem rather oncerns the actual management of the machine, until he remaining arm develops extra strength and exterity. The ignition can either be fixed, or ormally treated as such, if a lever is fitted. Single ever carburetters are obtainable, and are excellent. The gear can be controlled by a rocking pedal, with which clutch control can be incorporated. The main brake should be controlled by a pedal, and if separate clutch control is fitted, its pedal should be on the brake side, and be "picked up" by the brake pedal whenever the latter is operated. Personally, I should rely on one good pedal brake, and defy the law: in which case a hand exhaust lifter could be mounted under the throttle lever. But if a hand brake is insisted on, I should fit a pedal exhaust valve lifter on the gear pedal side, and add a hand lifter on the armless side for use with the kick starter, which would be mounted on the armless side of the machine. There is much to be said for pedal valve lifters: I have often faked them up, and enjoyed using them. After the war, some firm will assuredly make a speciality of modifying standard controls to suit men who have lost a limb. "ROAD RIDER."

THE "ENDS" OF HERTFORDSHIRE.

Some Charming Houses off the Beaten Track.

MANY places in Hertfordshire are known as "Ends." There is Ayre's End, Lawrence End, Blackmore End, Ansell's End, and a score or more of others. Mackerye End is a charming old house in a quaint mixture of the Tudor and Jacobean styles, lying about a mile north-east of Batford Mill, near Harpenden. It is difficult to find by road, and so is missed by the ordinary tourist as it lies well off the beaten track. For those who in happier times are fond of a quiet spin along the charming Hertfordshire bylanes, it provides a delightful excursion, and may be reached by proceeding along the Wheathampstead-Luton road and taking the second turning to the right after leaving the latte village at the very entrance to Batford. Thereafter th motor cyclist should bear to the right, and afte ascending a steep hill and negotiating sundry shar turns a good view of the house is obtained. It i mentioned in one of the "Essays of Elia," and at th close of the fourteenth century, the house then know as Macry End, was owned by Hugh Bostok an Margaret Macry his wife, who were parents of Abbo John of Wheathampstead, one of th most famous abbots of St. Albans in the abbey of which his interesting tomb is to be seen. Th sidecar combination is an 8 h.p military Matchless, which prove quite ideal for negotiating the stif gradients encountered in the narro lanes in the neighbourhood.



(Top) Mackerye End, Hertfordshire. The architecture is a mixture of Tudor and Jacobean.

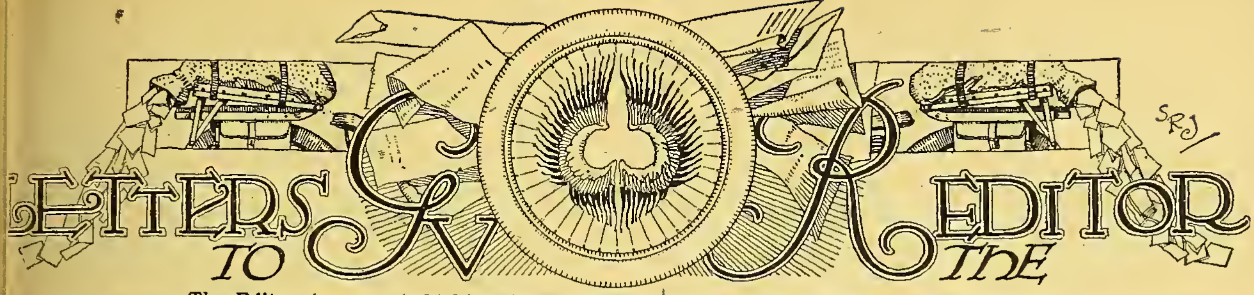
(Bottom) Lawrence End, near Chiltern Green. The outfit in both illustrations is an 8 h.p. Military Matchless.

* * *

The Motor Cycle Club of South Australia.

THE annual hill-climb of the above club was held at Sellick's Hill on January 28th. This hill is three and a half miles long with numerous sharp bends, rises 950 feet, and is thirty-four miles from Adelaide. The results, worked out on formula $\frac{W}{C \times T^2}$, were as follow:

	CLASS I.—SOLO MACHINES UP TO 300 C.C.	Fig. of merit.
1.	V. P. Elliott (Elliott-Villiers)	4,745
2.	E. Warren (Elliott-Villiers)	4,577
3.	R. V. Berriman (Triumph two-stroke)	3,446
	CLASS II.—SOLO, 300-351 C.C.	
1.	A. McKee (Kent)	4,790
2.	C. S. Lindsay (Douglas)	4,177
3.	G. A. Williams (Douglas)	3,636
	CLASS III.—SOLO, 351-600 C.C.	
1.	R. H. Abbott (Kent-Jap)	5,613
2.	P. W. Carnell (Lewis)	5,612
	CLASS IV.—SOLO OVER 600 C.C.	
1.	E. Ferguson (Indian)	4,157
2.	L. R. Buckeridge (Indian)	3,717
3.	E. C. Wagener (Blue Bell-Jap)	3,344
	CLASS V.—PASSENGER UP TO 600 C.C.	
1.	L. S. Eglinton (Kent-Jap)	6,360
2.	J. Wells (Zenith-Green)	4,377
3.	W. Courtney (Lewis)	4,329
4.	A. A. Burford (J.A.P.)	3,629
	CLASS VI.—PASSENGER OVER 600 C.C.	
1.	E. Ferguson (Indian)	3,999
2.	P. J. Coe (Indian)	2,995
3.	C. F. Cameron (Spacke de Luxe)	2,385
4.	F. Samson (Wyatt-Jap)	2,320



LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

RIVING EXAMINATIONS AND CERTIFICATES.

Sir,—Respecting the statement in the first paragraph of st week's leader, to the effect that proof of driving pacity is required, the recruit has only to ask the ecruiting Officer that he may be sent for a *trade* test. Here will be tested, and if he passes and is of the correct e and medical category will be posted as a D.R., provided at such are required. G.K.

London, W.

MPLE TYPE CARBURETTERS.

Sir,—I suppose it is a great presumption on my part—mere amateur—to venture to criticise "Chinook's" 8s. rburetter for the multitude; and no doubt, if he take y notice of this letter at all, it will be to come down on its author like a ton of bricks in your next issue. it it is my humble opinion that "the multitude" is not arly such a fool as he is sometimes considered, and in is case would much prefer to pay an extra 5s. for a cent float chamber than trust to "a fibre collar to take e hammering effect and provide a petrol-tight joint." etrol at 3s. 5½d. a gallon! W. G. ROBERTS.

RBURETTER ADJUSTMENT.

Sir,—I noticed a letter on "Carburetter Adjustment" in ur issue of March 14th. I have a 4-5 h.p. J.A.P. twin, d have had similar trouble. With a heavy sidecar I can t all the speed I want on the level and small hills with ts 000 and 3, but when I change on to the main jet, No. , while there is an increase of power, it is not in propor-on to the other jets. I can climb hills nearly as well on e first and second jets. A No. 10 jet seems to me to be ge, but it is far the most satisfactory.

I shall be pleased to see some hints in *The Motor Cycle* om some of your readers on this carburetter.

GEORGE B. AITKENS.

IE MUNITION WORKER AND HIS PETROL.

Sir,—Your impressions at a meeting of the N.M.C.F.U. ake very interesting reading.

To extend the bright idea of one of its members, why t ration the Army with munitions too? Would not that ake it easier for the tired munition workers?

As regards the question of riding for the benefit of one's alth, might I ask Mr. Torkington what he has done, or doing, to assist those who have been maimed in the ar and cannot cycle or even walk an appreciable distance? ounds rarely leave a man sound in constitution. Surely ese men are deserving of (one might almost say entitled demand) petrol to restore in some measure their shattered rves and general health—shattered, be it noted, in an deavour to protect this nation from the horrors of the un. ELREATH.

Seven Kings.

ETROL AFTER THE WAR.

Sir,—*Re* the paragraph in *The Motor Cycle* of April 4th, titled "Petrol after the War," in which it is alleged at the "Petrol Economy Officer" has stated "that *after* e war, anyone requiring petrol will be called upon to ow good cause why he (or she, presumably) should be ermitted to use it." Does this mean that the present strictions are to be continued indefinitely, and that we n no longer look forward to the time when we shall e permitted to tour, or take part in "hill-climbs" or trials"? Perhaps this "officer" contemplates the issue of a separate and distinct permit each time we wish to open our garage gates. Here is a decided opportunity for the newly formed M.U.P.A. to commence to justify its existence.

Might I humbly suggest that the "officer" in question be requested to give an explanation of the precise meaning he intended to convey by this extraordinary and disturbing statement? RAGS.

Laleham.

[It is not likely that restrictions will continue indefinitely, but, at the same time, those who expect "peace and plenty" to arrive together will doubtless be disappointed.—ED.]

BRITISH MAGNETOS.

Sir,—With reference to "Ixion's" comments on British magnetos, I should like to give a concrete example of how the British article has ousted the Hun in aero engine work.

On Rolls-Royce twelve-cylinder engines (used on Handley Page, De H4, etc.) an all-British magneto is exclusively used. Although the makers have a large stock of genuine Bosch magnetos of special design for aero work, they have discarded these in favour of the British article, which is *far lighter* and *more reliable* than the Hun machine; and, so far as I am aware, the British magneto in question was only originated during the war, and is quite unknown to motor cyclists, so it will be a pleasant surprise to post-war riders. R.P.O.

Derby.

BRITISH AND AMERICAN MACHINES.

Sir,—From time to time in your interesting paper that I receive each week I notice letters under "Overseas Correspondence" and also "Letters to the Editor" cracking up American machines. Well, if these people are Americans, well and good. Let them stick up for their machines every time by all means.

I am on active service, and have just completed two years' service on a British machine. Some of us who have stuck it right through have ridden from one end of East Africa to the other, *i.e.*, north to south.

Now if any American firm can produce a standard model machine of the same h.p. that is used at present, or even higher, which will stand up to the gruelling that these machines of ours have had, I should very much like to see it. This machine is to be treated in the same way; that means scant attention and practically no spares, also no protection from the weather.

This pretty well brings us to the point, taking the British and the American machines all round: Does the American really beat us? Our manufacturers may be a bit slow it is true, but though that may be you will find that the British machine will do exactly the same work at less cost, and at the end of it will be prepared to do the same trip again right away, when, more probably than not, the other will need an overhauling. I find that our manufacturers also are always pleased to receive suggestions or criticisms, and alterations are made where they think it advisable or necessary.

A point always in our favour is that our machines are always far simpler than the American, and many a time when I have asked a friend why he does not go in for an American machine he has simply said, "Too complicated for my liking!"

Of course, I have tried both myself, and I intend standing by the British every time, and wish good luck to the British manufacturers. G. MATHIESON.

MAGNETO REPAIRS—A WARNING.

Sir,—I would like to warn your readers of what I hope is an uncommon practice. In March, 1917, I sent my 180° magneto to a firm of repairers for remagnetising, but as they told me the armature was defective (which I do not believe) I agreed to have the same rewound. After repeated attempts to get them to return my magneto, whether repaired or not, I finally received their invoice on October 12th. A day or two later I received my magneto, and a more rotten job I have never seen. The frame is about the only part of my own magneto. The armature contact breaker, etc., I would not have picked off the scrap heap, and the whole thing was falling to pieces when unpacked, and is quite useless. I wrote and told them what I thought of it and themselves. I have had no reply to this letter of complaint. I know of another magneto treated in the same way by the same firm.

Rugby. F.J.C.

CONSERVATIVE RIDERS.

Sir,—I was rather interested in what "Kicking Horse" said under this heading in your issue of 28th March. Personally I entirely agree with his remarks that certain makes are not "the only motor cycles on earth," but cannot help sympathising with the "Untravelled Scotsmen" who put their faith in P. and M.'s. Their contention was probably the same as my own, that, having found a thoroughly satisfactory machine, it is unnecessary to experiment further.

I have had three Triumphs (all pre-war models), which gave me exactly what I wanted, and shall have no hesitation in buying the 4 h.p. countershaft model when it is available after the war, having seen the work it is doing at the Front.

I think this probably represents the opinion of that large section of motor cyclists who, before the war, were seen on the road with machines of the same make year after year, and who consequently were dubbed a "Conservative Brotherhood," and evidently rather looked down upon by the "Kicking Horse" type.

I would like to add that there are few machines on the market that I have not ridden and enjoyed, but I am still

Great Yarmouth. A ONE MACHINE ENTHUSIAST.

THE CASE FOR THE LONG STROKE.

Sir,—May I ask Dr. Alex. Lindsay some questions and make a few remarks upon his article? I ride a 67 × 95 mm. twin Ariel and a 62 × 70 mm. Levis, both long strokes, so am not prejudiced against the long stroke.

Easy Starting.—Why should a short stroke Triumph 85 × 88 mm. be less easy to start than the long stroke Triumph 85 × 97 mm.? Moreover, is it? Is there an easier starter than the more-than-square 3½ h.p. Ariel 86.4×85 mm. fitted with a decompressor? Dr. Lindsay says, "Next to the horizontal twin" the long stroke is the easier to start, admitting the superiority of the horizontal twin in this respect, yet most horizontal twins are "square" engines. Therefore easy starting is not dependent upon the stroke-bore ratio, and the point remains unproved.

Cool Running and Economy of Fuel and Oil.—Granted; but is this due to the long stroke or good design? In other words, is a long strong engine *necessarily* cool running and economical? Personally, I do not think so; but I think that a long stroke lends itself more easily to these ideals.

Speed and Power.—The *first* motor cycle to cover sixty miles in the hour was a "square" 85 × 88 mm. Rudge. Although this has since been beaten by the long strokes, it stood for some time.

The utilisation of the "expansile push of the burning mixture to the fullest extent" naturally spells efficiency, but the expansion is determined by the ratio of compression (approximately) and not by the stroke-bore ratio.

Engine Wear.—I would like to wager that if Mr. Norton would produce a "square" engine of equal capacity to his "long" one, and make the bearing pressures per square inch of bearing equal, there would be next to nothing to choose between the two for bearing wear, although the revolutions might be slightly higher. This would necessitate slightly larger bearings and compensate for the increased pressure on the piston.

Mr. Lindsay's last remarks upon speed and power are irrefutable, and form a powerful argument in favour of the long stroke. A great point overlooked by many is that, although the long stroke engine develops its power at a slower rate of revolution than the short stroke, the mean piston speed is much about the same. For instance, a 70 × 64 mm. A.B.C. geared 6 to 1 will produce the same piston speed as a 79 × 100 mm. Norton geared 3.84 to 1, road speed and wheel diameter being equal.

For quick comparison, the stroke-bore ratio of some of the engines mentioned in Mr. Lindsay's article are given:

3½ h.p. James ...	64 × 77 mm.	stroke-bore	= 1.20
3½ h.p. Norton ...	79 ×100 mm.	,,	= 1.26
Big 4 h.p. Norton	82 ×120 mm.	,,	= 1.46
3½ h.p. Triumph...	85 × 88 mm.	,,	= 1.03
4 h.p. Triumph ...	85 × 97 mm.	,,	= 1.14
4 h.p. J.A.P. ...	85½ × 85 mm.	,,	= 1.00
5-6 h.p. King-Dick	67 × 95 mm.	,,	= 1.41

Erith. T.S.

HOW MANY GEARS?

Sir,—"Lieut. (Retired)" does not state how many types of gears he has ridden. The type of gear has everything to do with the number of gears required. Now the Enfield two-speed gear and the P.M., which are of the expanding type, are very good—in fact, the only type which does not call for a third speed. They are the best all-round gears on the market in this class, with the advantage of having clutch and gear all in one. Now if a gear box is fitted, three speeds are necessary, as the gear ratio generally in a two-speed gear box is too big a jump from low to high. Say, for instance, when rounding a corner and then having to go up a gradient, or if you get stopped on a hill, this is where the middle speed comes in. Four speeds are not necessary. H. A. TOMBLIN.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—May I call your attention to the injustice to motor cyclists which is to be brought about by the new Air Force regulations?

As stated in your issue of March 21st, a motor cyclist becomes a non-technical man, whilst a petrol or steam car driver remains technical at considerably advantageous rates of pay, viz., a second-class M.T. driver receives 1s. 4d. a day more than a first-class motor cyclist, and has still the chance of 1s. more pay on promotion to first class.

Surely thousands of your readers who have enlisted through the medium of your paper will feel this a cruel injustice, having for the most part owned machines previous to the war, whilst many M.T. drivers have been taught to drive at the Government's expense in a comparatively short period.

I appeal to *The Motor Cycle* to take up the cudgels.

Farnborough. A SUFFERER.

A shell-damaged mosque in Palestine used by the Turks as an ammunition dump.

FRONT WHEEL BRAKES.

Sir,—Like F. R. Royston, I have often wondered why there are so few really efficient front wheel brakes fitted to machines. Even on a first-class motor cycle a bad front wheel brake is often to be found. For instance, on my own mount (a well-known make) there is fitted a rim brake, cycle fashion, which has proved to be useless. Not that I have often had occasion to use it. When I first bought the machine new, the brake was set so that it did not come within half an inch of the rim, and even after careful adjustment it barely touched the rim, much less stopped the machine in emergencies. Also on heavier sidecar combinations poor front brakes are found.

Is this not a question which needs more attention both by manufacturers and designers? R. J. HUTCHISON.

A SPORTING CHALLENGE.

Sir,—When I accepted Mr. S. A. Marks's challenge to run any 85½×85 J.A.P.-engined motor cycle I was under the impression that he wished to run under similar conditions to those under which the Triumph and Excelsior ran, and am surprised to see he wishes to run on Brooklands. I do not think it is fair to expect me to get my machine to London and run him on the track, as this would involve too much expense.

May I suggest that he meet me half-way between London and Cardiff, and let *The Motor Cycle* select the course up to thirty miles, which, I think, is long enough to decide which is the better engine?

I quite agree with Mr. S. A. Marks that both machines should weigh the same; my machine scales 4½ cwt. with sidecar. A.C.

Cardiff.

SECOND-HAND MACHINES.

Sir,—Thanks for the timely hints contained in a recent issue concerning the buying and selling of second-hand motor cycles. I advertised a short time ago in your columns for a Douglas model W. I received thirty-two replies. I selected about a dozen whose machines, from the descriptions given, seemed to be of sufficiently late date to be suitable, and I wrote asking for the numbers of the engines.

One would-be seller only replied to my letter, from which it would seem that the remaining eleven had given me dates and descriptions that would not bear investigation.

Another point disclosed was the exceedingly high average price that was asked for the machines, and this notwithstanding the petrol famine.

May I ask if some of your readers will give the results of their experiences with the Humber flat twin? C.

Aldeburgh.

A POST-WAR IDEAL.

Sir,—I have been reading *The Motor Cycle* with great interest lately, especially as regards the future motor cycle. The V twin has undoubtedly done marvellous things in the past, but I think the majority of riders of that type would soon discard it were a better engine from an all-round standpoint put on the market. For heavy and fast sidecar work I do not think the flat twin is good enough. Of course, we do not know the plans of our premier makers, but I *do* wish such firms as the A.J.S., Matchless, Sunbeam, etc., would turn their attention to the four-cylinder for sidecar work. A really good English-designed, four-cylindered, four-speed, shaft-driven machine would command a big market. It should be sprung front and rear, and have detachable wheels, and be well protected from mud (engine as well, *à la* Scott). But what about the price? I see sidecar outfits are being offered at £120 new, and without dynamo lighting. One could get a light car almost for that. Such a price will kill the trade.

B.E.F. F. JOHNS (Sapper, R.E.)

Sir,—I have been very interested in the articles and letters describing the "ideal machine" from the points of view of various riders, and submit my ideal from the point of view of what I may describe as the sporting tourist, i.e., a solo rider who likes to maintain a high average over a long run, and for whom power has the greatest possible fascination.

I find the most wearying feature of a long run at speed is the great clatter set up by the average medium power machine at anything over 30 m.p.h. Engine and transmission are both in need of much improvement here, also the various detail work and accessories. As things are at present, noise seems to be inseparable from high engine revs., as, although engine balance has a great deal to do with it, the flat twin is usually a very noisy engine, in spite of its perfect balance. Therefore I am in favour of a big engine, always working well within its capacity, and capable of pulling on a high gear.

With regard to transmission, I think the ratios provided by the average three-speed box are unsuitable for solo use. Generally speaking, the drop from gear to gear is too big by far.

In view of these considerations, my ideal would be as follows:

Engine.—750 c.c., 90° twin, enclosed valves, inlet overhead.

Transmission.—Zenith-Gradua countershaft with silent chain in oil bath to countershaft.

Frame.—Duplex, this being the only type suitable to accommodate the 90° twin comfortably. (By the way, I notice that "Wharfedale" has also been struck by the excellence of this type, so I may claim expert approval here.)

Springing.—Front Druid Mark 2, rear Zenith, but a modified lighter design.

Control.—Bowden cable with twist grip handles.

Accessories.—Standardised with machine; brazed-on lugs provided for fitting where possible.

General.—The whole machine to be built as light as possible consistent with sufficient strength for use as a *high speed solo mount only.*

I have satisfied myself, by means of sketches, that a very nice lay-out can be produced on these lines. S.C.C.

Penge.

Sir,—With regard to "Ideal Machines," if anyone wants a thoroughly simple, efficient, and reliable machine, only two speeds, and lightness, I think he will find the 2¾ h.p. Calthorpe-Jap fill his requirements. Although I never rode the old 2¾ h.p. De Dion, I should imagine that the J.A.P. engine is about as flexible as any. The Calthorpe is simple, as it has two speeds and clutch combined in the Enfield gear. There are no gear teeth to strip, and the gear will stand any amount of ill usage. It is light and reliable, and quite fast, capable of about 46-48 m.p.h. without any tuning. When fitted with the Amac semi-automatic carburetter it is very simple to drive, the throttle being the only lever to manipulate, once the air is opened. The frame is also well designed, having a straight top tube, which makes for strength.

May I add the usual disclaimer? CADET.

Dartmouth.

CARBURETTER ADJUSTMENT.

Sir,—I have had Binks three-jet carburetters on three different machines, two twins and one single, and I know and have suffered from Mr. H. A. Connell's symptoms, though I have always managed a cure. In two cases out of the three a much larger jet was the remedy, *e.g.*, my present machine (79×100 single) refuses to run on a smaller main jet than 9, and even with that there is one choking spot—no adjustment of bottom air will cure it. Except for this one spot, over which I always hurry, the engine responds in Norton fashion over the whole range of the throttle. In the other case—a 60° twin engine—the cause was more obscure. I could never open on to the main jet at all, no matter what size I put in. I tried six different sizes, and finally I discovered that the leather jet damping pad was saturated with water. Once that was dried, a No. 7 jet worked the oracle. The pad seems to have been kept permanently damp by water trickling down the throttle cable on to the top of the barrel whenever I was out in the rain.

I wonder if Mr. Connell tests the jet sizes with a fine needle; I have found the numbers decidedly unreliable. If he is using a Binks hot air elbow, has he inspected the *inside* of it? I have on occasion found the inside diameter reduced by about 50% by part of the sand of the casting being left *in situ;* consequently the fitting of the pipe caused an enormous drop in power until the elbow was cleared. Finally, is his "jet-table" petrol-tight? I had one that was not, and it was the source of endless bother.

(REV.) J. M. PHILPOTT.

A REMARKABLE TWO-STROKE ENGINE.

Develops 37 h.p. and Weighs 30 lb.

THE following is a brief description of a very remarkable two-stroke engine of marvellous power. The engine is a single-cylinder, single-acting two-stroke, with forced feeding—one cannot call it induction. The cylinder is of steel, water-cooled, circulation being on the thermo-gravity system. No separate radiator is provided, the whole of the cooling water being contained in the steel water jacket which surrounds the cylinder. In consequence of this the capacity of the water jacket is very large compared with the cylinder. Where continuous running is required an external supply of water can be arranged to replace any loss due to evaporation. The engine differs from the orthodox type in that not only does the piston move, but the cylinders also, and the reciprocation of the latter operates the whole of the timing mechanism.

Ignition is effected without either magneto or coil and battery, in spite of which starting up from cold is absolutely instantaneous, and full power is immediately available, no warming up being required, unless, of course, the cooling water is frozen, which naturally should not be allowed to happen.

In view of the terrific horse-power developed, it is not surprising that the cylinder pressure is somewhat higher than that which obtains in the ordinary motor cycle engine. The latter seldom reaches a maximum of 300 lb. per square inch. A modest pressure of about 38,000 lb. per square inch may therefore seem a trifle high. It is a hundred and twenty-seven times as much as the motor cycle maximum.

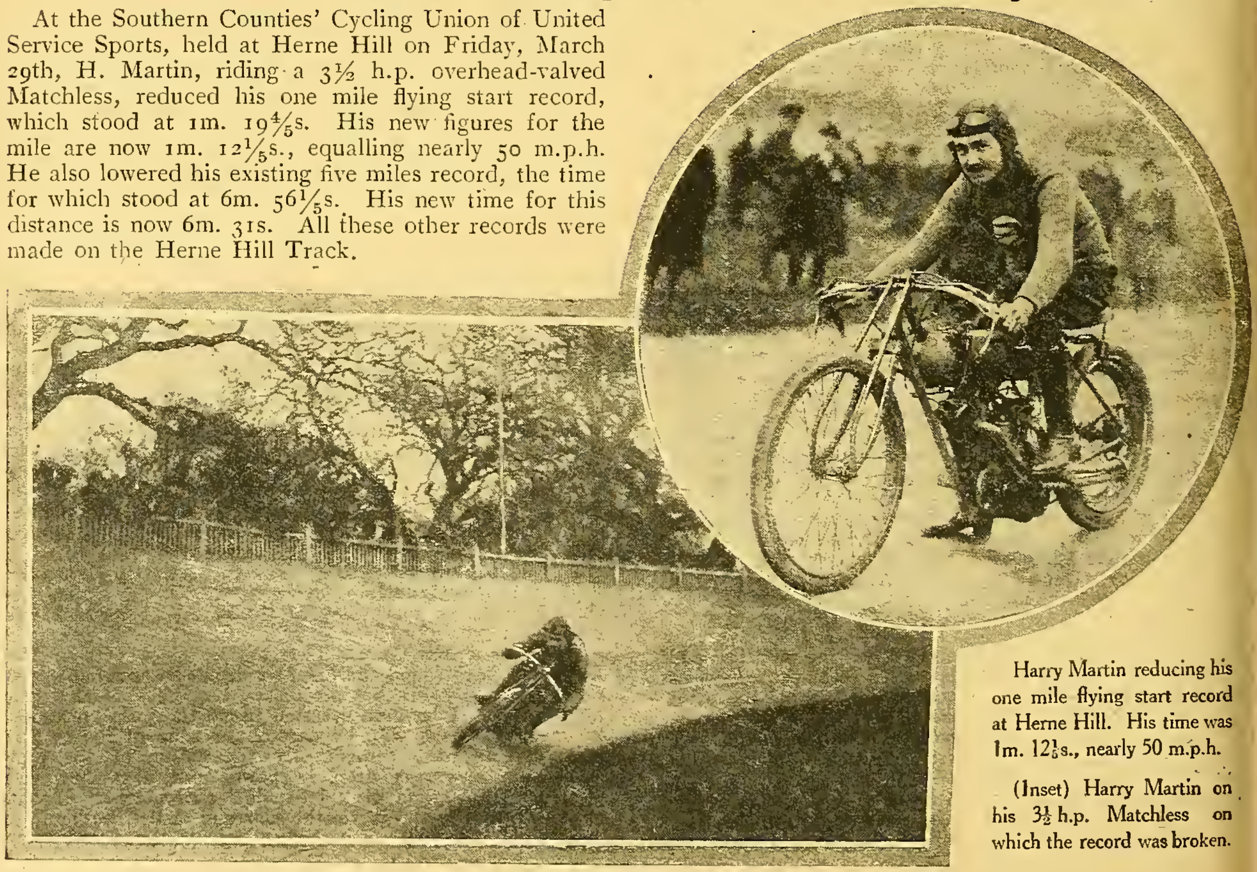
The fuel is not petrol—nor gas. It is something very special, and, although rather high in price (and at present unobtainable by the general public), there seem fortunately to be ample supplies. Carburetter? There is no carburetter to flood and leak air in where it is not wanted. There is only one thing against this engine—it is not at all flexible.

Honestly, the facts are as stated, exactly. But to drop the camouflage and display this wonderful engine. The riddle is really very simple. The cylinder is a barrel, the piston a bullet, ignition by percussion upon fulminate of mercury, and the fuel cordite. The *tout-ensemble* is called the Vickers automatic machine gun, water-cooled, and fires at the rate of 500 rounds per minute, the mechanism being operated by the recoil of the barrel. It is, in fact, a small internal combustion engine, and actually develops over 37 horse-power at 500 rounds per minute, with a bore .303in. and stroke 28in.

T.S.

Record Breaking on Good Friday.

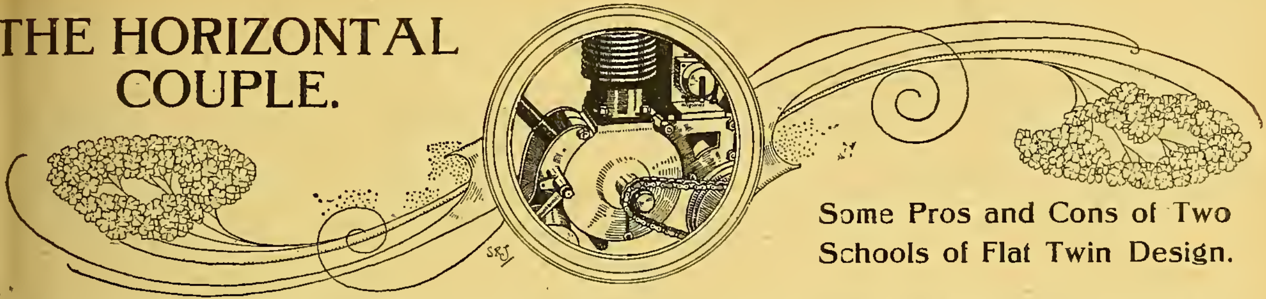
At the Southern Counties' Cycling Union of United Service Sports, held at Herne Hill on Friday, March 29th, H. Martin, riding a 3½ h.p. overhead-valved Matchless, reduced his one mile flying start record, which stood at 1m. 19⅘s. His new figures for the mile are now 1m. 12⅕s., equalling nearly 50 m.p.h. He also lowered his existing five miles record, the time for which stood at 6m. 56⅕s. His new time for this distance is now 6m. 31s. All these other records were made on the Herne Hill Track.



Harry Martin reducing his one mile flying start record at Herne Hill. His time was 1m. 12⅕s., nearly 50 m.p.h.

(Inset) Harry Martin on his 3½ h.p. Matchless on which the record was broken.

THE HORIZONTAL COUPLE.



Some Pros and Cons of Two Schools of Flat Twin Design.

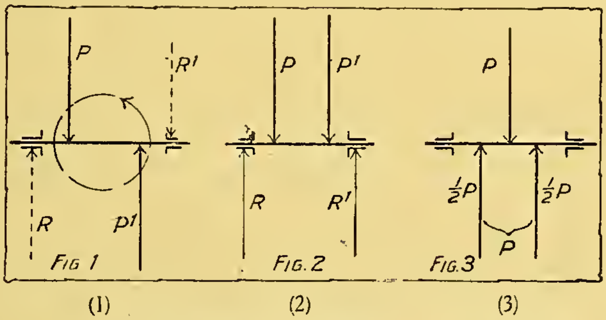
SOME time ago in criticising certain flat twin engines the writer expressed the opinion that the more frequent troubles experienced were due o the inherent unbalanced couple inseparable from he accepted design now in favour.

Since the appearance of that opinion confirmation ias been forthcoming from others who have had xperience with the horizontally opposed engine in ther fields of engineering, and it is to be anticipated hat the point will not be without its effect on the levelopment of the type.

Before passing to any practical consideration, it nay be as well to explain for the benefit of the non-echnical reader that "a couple" is the effect on a ody of the application of two equal and parallel orces, of opposite direction which cause that body o rotate about a point midway between the points of pplication of the forces.

A couple can only be balanced by two opposing orces which create a couple of equal moment and pposite turning movement.

Diagram 1 represents the crankshaft of a horizontal win engine, in which the forces applied from the ylinders are shown by the nes P and P¹, and these orces produce an anti-lockwise couple (as indiated). The reaction of e bearings R R¹ gives the ouple of equal moment nd opposite sense, which ounteracts the tendency of e crankshaft to rotate orizontally.



(Fig. 1) Representing the crankshaft of a horizontal twin engine. The forces applied from the cylinders are shown by the lines P and P¹.

(Fig. 2) Showing that in the vertical twin-cylinder no unbalanced couple exists.

(Fig. 3) A three-throw type of crankshaft in which all the forces are in balance.

The second figure shows the same diagrammatic anner a vertical twin linder, in which it will be bserved that no unbalnced couple exists, since this case P and P¹ are oth applied in the same irection. In other reects, however, the vertil four-cycle twin is not a successful type.

The effect of the unbalanced couple in the horiontal twin does not appear to the rider in the form f vibration such as that with which we are familiar rising from the compromise lack of balance of the eciprocating mass in a single-cylinder engine, but it possible that it may have more than a little to do ith a number of minor engine faults, which, curiously hough, have not shown themselves in engines free om this mechanical defect.

In order to prevent the shaft from rotating in a horizontal plane (not to be confused with that function of freely revolving upon its axis, which knutty D.R.'s so ardently desire to be fulfilled when they adorn their flywheels with the request "P.T.O.") it is very necessary that the engine case and bearings be of special stoutness and rigidity; indeed, it is quite common practice to use lighter main ball bearings in 3½-4 h.p. singles than in small flat twins.

In America, where the flat twin high power engine has been largely used for farm tractor propulsion, experience has proved the necessity for extremely sturdy bearings and housings.

Considering the fact that the moment of a couple is proportionate to the distance between the forces creating it, it becomes obvious that the narrower the bearings of the crank throws and the intervening web the smaller is the disturbing effect.

Limiting the Effect of the Couple.

The most suitable form of connecting rod and bearing to limit width is the roller big end of the Scott pattern, but its practical application to a one-piece crankshaft is not easy. The designer of the A.B.C. engine, however, has more than one method of circumventing the difficulty, and if his machine proves capable of long and reliable service in the hands of the average rider no doubt his attention to this particular feature will be one of the contributory causes of its success.

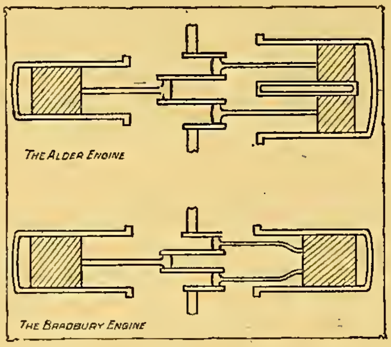
In all automobile work, where price and everyday use are of prime importance, it is often necessary to adopt a compromise rather than incur the extra expense in obtaining what may ultimately prove to be a mere theoretical advantage, and it is quite possible that the narrow, two-throw crankshaft will establish itself as the better working solution of the only mechanical objection to the horizontal twin than will the type to be reviewed hereafter. At the same time, it must not be overlooked that with the former a slight horizontal couple cannot be eliminated, though it can be reduced to very small importance, whilst in the latter perfect mechanical balance is obtained within the crankshaft itself.

The Horizontal Couple.—

Returning to the properties of couples, the existence of a couple is consequent upon the application of two parallel equal forces of opposite sense, and it cannot be balanced by a single force. Now, referring to our diagrams, if we divide one of our forces P into two halves and apply these to the shaft at two points they may be balanced by one force, the remaining undivided P^1 acting at a point midway between them. (Diagram 3.)

This arrangement gives the three-throw type of crankshaft in which all the forces are in balance.

Two designs on this principle have been brought prominently before the writer's notice. The first, the patent of Mr. Alder, employs two pistons and rods, with a common combustion head opposed to one large cylinder; whilst the second, the 3½ h.p. Bradbury, has two equal cylinders with one forked and one single connecting rod.



Two designs of engines in which all the forces are in balance.

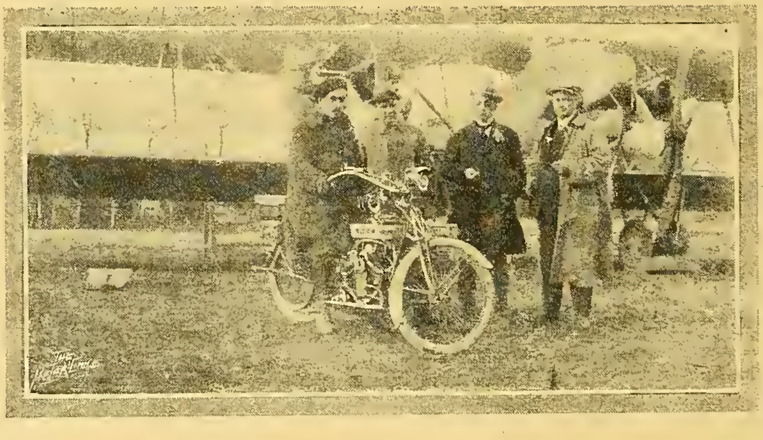
Manufacturing Difficulties.

The manufacture of neither of these engines would be as easy nor as cheap as of those of the two-throw type, although the Bradbury design seems to offer least difficulty, since it merely calls for the balancing of the weights of the two connecting rods, whereas the Alder engine not only has the problem of balancing two rods and pistons against one, but has the even greater difficulty of adjusting the volume of the common combustion head of the double-bored cylinder to equal that of the single-cylinder and to obtain the same compression ratio. From the works standpoint also the unsymmetrical cylinders would necessitate a double number of patterns and a double stock of parts; while, speaking from a fairly large experience of cylinder and crank case boring, machine shop costs alone would more than turn the scale in favour of the Bradbury design. The conventional appearance and external symmetry of the latter are also features not to be ignored, especially so since nothing is sacrificed to obtain them.

The writer certainly favours the three-throw crankshaft, despite the fact that it is so seldom used, and it remains to be seen, with the advent *(après la guerre)* of more firms into the flat twin arena, whether this type will come more to the fore, as it certainly deserves to come. Possibly we shall be compelled to await a decision on finality in flat twin design until an entry into the lists of something that everyone will want to buy. WHARFEDALE.

4 h.p. Douglas for French Despatch Riders.

THE principals of the Douglas factory have just returned from an interesting journey in France. Taking with them two of their well-known 4 h.p. sidecar outfits for trial by the French military authorities, they carried through a successful week's test, and the machines were left behind to undergo further hard work at the hands of the French inspectors. If the result is satisfactory, and there can be little doubt on that point, it will probably lead to a regular supply of machines for the use of French D.R.'s who at present handle a very mixed lot of motor cycles.

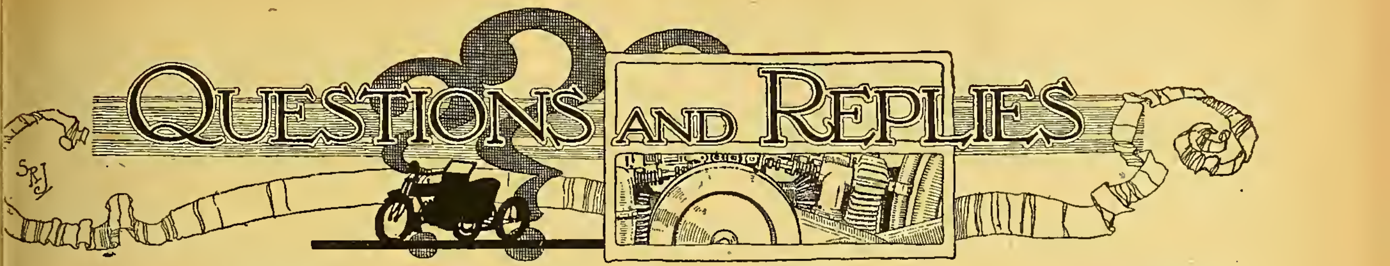


A group of Douglas representatives in France. Reading from left: M. Letroid, maker of the famous bombing aeroplane bearing his name; W. A. Davis, of the Paris Douglas depôt; Mr. S. L. Bailey; and Mr. W. W. Douglas.

During the trip, Messrs. W. W. Douglas and S. L. Bailey had the privilege of a lengthy flight in one of the large twin-engined Letroid bombing planes over the war zone. M. Letroid, the designer of this fine plane, is chatting with Messrs. Douglas and Bailey in our illustration. The plane embodies many striking departures which it is not desirable to describe.

It is also interesting to note that Messrs. Douglas and Bailey were staying in Paris when the unfortunate explosion at a grenade depot occurred, and give a striking description of its startling nature.

At the request of the Association of British Motor and Allied Manufacturers, Dr. Addison, Minister of Reconstruction, has nominated Mr. H. C. B. Underdown to serve upon the Engineering Trades (New Industries) Committee, and has authorised the formation of a Branch Committee for the Motor Industry, which has been formed as follows: Mr. Bernard Caillard (vice-chairman) (director of Wolseley Motors and managing director of the British Lighting and Ignition Co., Ltd.), Mr. Edward Powell (president of the S.M.M.T.), Mr. J. B. Stocks (general manager of Components), and Mr. Horace Wyatt (secretary).



QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

›ic Capacity and Horse-power Formulæ.

? Would you explain how to calculate the cubic capacity of an engine? Also the horse-power, when given the bore and stroke?—ENQUIRER.

e cubic capacity is obtained by means the following formula: $D^2 \times S \times .7854$, ere D = bore of cylinder and S = oke in centimetres. The answer will in cubic centimetres. To find the se-power, perhaps the most accurate thód would be Hospitalier's formula, ich is as follows: Square the radius the piston in centimetres, multiply by stroke in centimetres, multiply by number of revolutions per minute, ide by 1,000 and again by 75; 75 ogrammetres per min. equal 1 h.p. ench). The formula may be written efly as follows:

$$\frac{\times S \times N \times \text{revs.}}{75{,}000} \quad (N = \text{No. of cylinders}).$$

Choice of a Machine, etc.

? (1.) What type and make of motor cycle would you recommend me to get for a fairly hilly locality? My weight is 10 st. 4 lb. (2.) I am engaged in war work on he land as supervisor of a cow-testing ssociation, and have to visit the mem-ers who reside in various districts from ne to fifteen miles apart in connection ith their work. In order to do so I eed a motor cycle this year. What ourse should I adopt to procure one? .) Can I get a petrol permit, and ow? (4.) This work is under the epartment of Agriculture, by whom I m partly paid. One of the local ustices of the Peace is president of his association, and can testify to my eeds.—DUBLIN.

Any modern lightweight should satisfy ur requirements, the actual make de-ding upon personal preference and amount you are willing to spend. (2.) you require a new machine you should ly to the Priority Branch of the istry of Munitions for a class "A" ificate, which will be necessary before can purchase a new machine. If, vever, you require a second-hand chine, and such a machine should be te satisfactory if carefully chosen and too old, you may obtain one from dealer with a good reputation or ough the small advertisement columns *The Motor Cycle.* (3.) You should ly to the Petrol Controller, 19, Berke- Street, London, W.1. (4.) The evi-ce of the Department of Agriculture y be necessary, but the Petrol Con-ller will inform you if this is so.

Gear Ratios.

? Hearing that a friend of mine has left me a 2½ h.p. 1916 Calthorpe-Jap fitted with an Enfield two-speed gear, I should be glad if you would let me know: (1.) The two gear ratios. (2.) What gradient it could climb; I weigh 12 stone. (3.) What speed I could average on short runs. (4.) Would it be suitable for short tours?—J.D.W. (R.A.)

(1.) The top gear is 5½ to 1 and the bottom gear 10-12 to 1. (2.) About 1 in 6. (3.) It would average on tour about 20 m.p.h., with a maximum of 35 m.p.h. (4.) It would be suitable for tours.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

THE NEED FOR ECONOMY.

Owing to the present drastic restrictions on the import of paper, the most rigid economy is necessary, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week, thus avoiding chance buying, which may lead to wastage owing to copies being left unsold.

Magneto Condenser Trouble.

? I have a 2¾ h.p. Moto Rêve motor cycle, and have discovered that the magneto has something wrong with it, as the wax that keeps the contents of the condenser in position has begun to melt and find its way on to the pole pieces. I discovered that a spark occurred at the platinum points when running, and I was also troubled with hard starting and very faulty running and erratic missing. Do you think that the trouble is a faulty condenser shorting owing to the wax melting? Could I test for a short by connecting up the condenser to an accumulator and voltmeter?—A.J.C.

We are afraid that the the test you suggest would not be at all a conclusive one. If the connections render it possible it would only prove that the condenser was faulty, which already appears to be the case owing to the extra sparking at the contacts. The only course that we can safely recommend is that you send the magneto complete to a magneto repairing specialist. The repair should not be an expensive one if you placed it in the hands of a satisfactory firm.

Unequal Firing.

? (1.) I own a 5 h.p. V twin, and have considerable difficulty in getting both cylinders to fire with equal regularity, apparently by reason of one cylinder drawing a different strength of charge from the other. I have spent much time in checking the magneto and valve timings, etc., and am led to conclude that the unequal periods between the successive suction strokes of each cylinder cause the velocity of the gases to have a "banking up" effect on one cylinder more than the other, and thus to enrich this side at the other's expense. I should be pleased to know whether you think there is anything in my theory or not. If so, one would naturally suppose that a carburetter for each cylinder would overcome this difficulty. (2.) Also, in order to follow this trouble further, I propose fitting two separate exhaust pipes—one on each side of the machine—so as to be better able to trace the cylinder which fires unevenly, and this possibly could be located by listening for the offending side whilst riding. Now, would the separation of these pipes cause any appreciable drop in efficiency? It appears to me that it would, by reason of the mutual help the velocity of the exhaust gases in the single pipe have upon each other. Also for two outlets I should imagine there would be considerably more resistance offered by the atmosphere.—H.T.D.

(1.) The trouble of which you complain is not an uncommon one in the case of a V twin engine. The difference in power between the two cylinders may be due to unequal compression, unequal strength of the valve springs, air leakage at joints, or possibly incorrect tappet adjustment. (2.) Your idea as regards two separate exhaust pipes is a good one, because there will then be no trouble of one exhaust interfering with the other, and, of course, you will be able to check more easily which cylinder is firing weakly, and the fact of fitting two separate exhaust pipes might tend towards greater efficiency. It is absolutely desirable that the exhaust from each cylinder should have perfectly free egress and should not be obstructed.

Joining the R.A.F.

I have been a motor cyclist for the past five years, and have a thorough knowledge of motor cycles and a fair knowledge of motor cars. Would you kindly let me know if there are still vacancies for motor cyclists in the R.A.F.? If so, kindly send me further particulars and where to apply for enrolment.—W.O.

You should apply to your local recruiting officer, unless you are a conscript, in which case we doubt if you will be allowed any choice of regiment or unit.

R.A.F. Cadet's Kit Allowance.

Could you tell me at what stage in his course, allowance is granted for the provision of outfit to a cadet in the R.A.F.? I take it that this would occur on his becoming a flight cadet after leaving School of Armament, but as you appear to be very well posted in these particulars I think perhaps you will not mind passing on any information to interested readers.—W.R.W.

A cadet to the new R.A.F. is granted uniform on joining as a cadet, and kit allowance on being gazetted, as usual. The expense of the uniform is deducted from the kit allowance.

Mysterious Two-stroke Trouble.

I ride a two-stroke, and shall esteem it a favour if you can help me out of the following difficulty. I have taken it to two or three different repairers, but they do not seem able to do much good. It runs well for quite a long time, and starts at the first pull round of the back wheel, and then it takes a fit and cannot be made to start under any circumstances. It recently ran well for about twelve miles, when I had to make a stop. On trying to restart I could not get it to go for some time, when it ran irregularly for two or three miles, and then suddenly stopped with a big splutter. Everything seems to be in perfect condition—plug clean, no leaks at joints, compression good, jet clear, no air lock, good big spark, plenty of petrol, timing correct, silencer not choked, and platinum points all right. Everything seems to be as it should be, but the engine will not start. I took it to a garage, and the owner tried all the afternoon, but could not get it to start, and I have now left it for a general clean up. My crank case has not a drain pipe. If oil and dirt collected there, would that prevent the machine from starting? I asked the man with whom I left the machine to fit a drain plug, but he says he is unable to do so, as the crank case is made of aluminium and is too thin, and that the hole would get larger. Is this correct?—F.J.C.W.

Diagnosis of your trouble is certainly rather difficult. Are you quite sure that the principal ports are quite clear, and that none of the passages in the induction and exhaust system is choked up? Also, the petrol feed system should be carefully checked. If the feed of petrol is temporarily interrupted, your difficulty, of course, would be fully explained. We have heard of similar cases being entirely due to an air lock in the petrol tank of a purely temporary nature, and consequently difficult to determine. A vapour lock in the petrol pipe, if this is too close to the exhaust pipe or cylinder, would have the same effect. Another cause of the trouble might be due to the magneto. When the engine stops, have you ever tried putting your thickly gloved hand on the sparking plug terminal before the machine has entirely lost way? If you feel no shock, this would rather point to the probability that the magneto had temporarily ceased to spark, whilst after a short rest it may be quite correct again. Also you should search carefully for air leaks at the cylinder joints, induction system, and crank case joints. If, of course, you have an unsuitable plug, it is possible that this may be the cause of your trouble, although it is very unusual indeed that a plug will cause an engine to refuse to start soon after it has been running satisfactorily. We do not think that the absence of a drain plug in the crank case has anything to do with the trouble; but there is no doubt that such a plug would be a very useful fitting. The repairer's trouble is caused by the absence of a boss on the crank case in which to screw the plug, but it should be possible to screw or rivet on a loose boss.

Use of Petrol for Health Riding.

My principal reason for taking up motoring was because my wife was an invalid, and her only possible chance of getting out was by having something brought to the door to take her. I bought a motor cycle and sidecar, and my wife and I have had some pleasant outings. Unfortunately my wife is not any better, and, so far as I know, has no prospects of going out this year. If you can kindly inform me whether I am actually barred from the use of petrol, under the circumstances, you will extremely oblige.—T.G.

You cannot legally take out your wife in the sidecar unless you can obtain a doctor's certificate to say that such journeys are necessary for her health. Even then you would not be strictly covered in the eyes of the law; but it is possible that such a certificate would induce a bench of magistrates to adopt a lenient view of the case were action taken.

Removing a Crank Case Ball Race.

My motor bicycle is a tw speed, chain-driven, 1913 mo 3½ h.p. B.S.A. I have a n crank case ball race, which want to fix in the crank ca but I cannot do so, as I am unable get the old ball race out. Please me know what tool I require, a how to get the old ball race out of t crank case.—W.J.S.

The makers of your machine recomme the following method, but other ma facturers prefer to use a screw-pre To remove the ball bearing now in t crank case, the crank case half should held in the gas flame, so that the h will expand the aluminium and allow t ball race to drop out, but care sho be taken to see that the heat is sufficient to interfere with the temper the ball race. If the crank case is ca fully watched while it is heated in manner suggested, the ball race w probably drop out of its own accord, matters can be assisted if the ball r is given a few sharp taps after t crank case has been in the flame for short time. When the old ball race been extracted in this way, the new should be inserted immediately, bef the crank case is allowed to cool.

RECOMMENDED ROUTES.

TRACING TROUBLES

MOTOR CYCLE FAULTS, THEIR IDENTIFICATION AND THEIR REMEDIES, SIMPLY AND FULLY EXPLAINED.

Third Edition

(Revised).

In this edition considerable changes have been made, all obsolete matter has been taken out and new material has been added to bring it up to date.

The section which deals with the two-stroke type of motor cycle has been enlarged and re-arranged in view of the vastly increased number of two-stroke engines now in use.

A new section dealing with electric lighting dynamos as applied to motor cycles has been added.

The Book that helps Motor Cyclists out of their Troubles.

¶ All motor cycle riders, and especially those using their machines for vital work, should keep a copy of this little volume handy. It will help them out of many a difficulty.

¶ Not only does it show how to locate a fault quickly, but also provides a remedy for it when it has been found. All conceivable motor cycle failures are dealt with by the author.

Price, 1/- net. By Post (Home or Abroad), 1/2

From ILIFFE & SONS LTD., 20, TUDOR STREET, LONDON, E.C.4,
and all leading booksellers and bookstalls.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller. but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

The Committee of Reconstruction.

THE bare announcement made last week of the formation of a committee to look after motor interests as a part of the engineering trade, in matters relating to reconstruction, will probably strike the majority of our readers as something which does not concern them at all intimately. Were we to jump to any such conclusion we might later on find ourselves very much in the wrong. The first point which connects this matter with motor cycling interests is to be found in the inclusion upon the committee of the name of Mr. Stocks, who, as general manager of Components, Ltd., is closely connected with the Ariel motor cycle. Mr. Stocks was recently elected chairman of the Motor Cycle Section of the Association of British Motor and Allied Manufacturers upon the retirement of Mr. Charles Marston, of the Sunbeam, necessitated by the loss of his father and brother. The inclusion of Mr. Stocks on the committee of the motor industry shows that the motor cycle is to be regarded as coming within the sphere of operations of the committee. Incidentally, this is, we believe, the first occasion upon which the policy of associating the motor cycle with the motor industry, by forming a special branch of the A.B.M.A.M., has been clearly justified as affording a means of getting official consideration for the motor cycle on account of its relation to the motor car. It is not probable that the Minister of Reconstruction would have considered any suggestion for the formation of a committee specially to watch over motor cycling interests, and therefore, had not this liaison existed, our industry might have been left in the cold.

The next point is that the work of forming sub-committees specially representative of various sections of the industry is in progress. Doubtless, one of these sub-committees will be representative of the motor cycle manufacturers, and at this juncture we should like to emphasise the importance of full collaboration between the Association of British Motor and Allied Manufacturers and the Cycle and Motor Cycle Manufacturers' and Traders' Union in this matter. Properly handled, the position may serve to bring these two bodies into permanently intimate touch with each other. Badly handled, it may lead to a dangerous breach.

Now we come to the real point of the whole matter from the standpoint of the motor cyclist. Assuming that the manufacturer of the motor cycle is well assured of a hearing from the Government with regard to all his reconstruction proposals, the motor cyclist may reasonably expect to benefit. It will not do the manufacturer much good to get materials and permits for the construction of new models, or facilities for increasing his works and output, unless he can sell his machines, and his ability to sell depends on whether the motor cyclist is prepared to buy. This in turn depends on a number of things. However bad the conditions, there will always be some riders keen enough to buy and use their machines. There must be many other potential buyers, however, who will not be prepared to come into the market unless they are assured that they are not going to be too heavily taxed or made the subject of grandmotherly legislation. They will also want to feel certain that they are going to have decent roads upon which to travel. It is now in the power of the manufacturers to point out directly and strongly to the Government that unless these conditions are assured they will not be able to sell enough of their machines to keep their plant and their men busy. Thus, by a rather roundabout way, we come to see how the formation of this new committee for the motor industry may react to the very distinct benefit of the motor cyclist. We trust that the manufacturers will all along bear in mind their dependence upon the rider and the need of catering for his welfare. If they do so, all will be well, and very much to the benefit of all concerned.

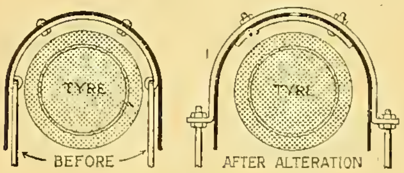
An index to the advertisements in this issue will be found on the page facing the back cover

IDEAS: Useful and Ingenious.

MUDGUARD CLEARANCE.

An easy way to get over the difficulty of mud-clogging in guards not having sufficient clearance is given below.

Cut off the stays of the front guard as close up to the guard as possible, and thread each end for ¾in. Remove the arch and rivets entirely from the guard, and cut off the remains of the stay ends, leaving only a short arch. Make of scrap metal a pair of arches to go over instead of inside the guard, and a few odd nuts and pins will complete the job as in diagram. The outside stays give a stronger hold on the guard, and when the stay ends are not inside, little or no clogging occurs. Why they were ever put inside is a mystery.—Cyril Jones.



Remedying the fault of insufficient mudguard clearance.

SIMPLE CONTROL FOR A PHILIPSON PULLEY.

The following description is of a simple control for a Philipson pulley:

The top front cradle plate is taken from the engine and a long special stud made, as shown in fig. 1. On to this is fixed a brake shoe to brake, of course, on the Philipson drum. A Bowden cable is attached to the wire which runs through the shoe and is fixed to some suitable part of the machine behind the pulley—in this case to the footrest. The casing of the cable butts up against the front of the shoe, as shown in fig. 2. The Bowden wire is then taken to a suitable lever on the bar. When the lever is pulled, the outer casing of the cable pushes the shoe against the pulley. The idea is well worth the small amount of trouble involved.—W.J.R. (Birmingham).

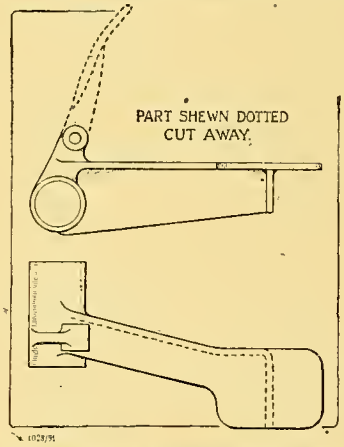
CABLE SECURED TO FOOTREST

A control for a Philipson pulley.

ALTERING A DOUGLAS BRAKE PEDAL.

Riders of those Douglas models which have footrests fitted in place of footboards, and on which the pedal that operates the rear brake is fitted in a more or less vertical position just forward of the starboard footrest, may be interested in hearing of an interesting alteration which makes the operation of the back brake easier and more certain.

The sketches will show how the alteration was carried out. The pedal now lies snugly just inside the front part of my right foot, and by turning the foot slightly inwards the toe falls naturally on to the new brake pedal, while the arch still remains comfortably on the footrest. Arranged thus, the brake is usable, and can be relied upon in an emergency.



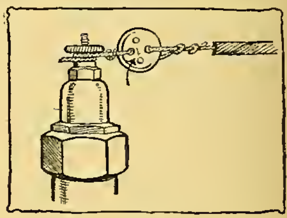
Alterations to a Douglas brake pedal.

The alteration was carried out by welding two pieces of 10 s.w.g. mild steel plate together to form a lever of Γ section, and then welding this lever on to the base of the existing pedal. That part of the pedal immediately above the boss which is tapped to take the pin that carries the yoke end of the brake pull rod was cut off.

A heel-operated lever would doubtless have been preferable, but it would have been very much more elaborate in shape, as it would have had to be formed to clear the footrest tube. The length of the brake pull rod would also have been increased, so the idea was given up, and the lever fitted as shown.—F.B.S.

A SIMPLE SPARK GAP.

This is made by interposing an ordinary bone sleeve button between the sparking plug terminal and the high-tension wire. One end of the wire is looped through one hole in the button, and the opposite hole in the button is connected to the terminal by means of a piece of copper wire, as shown clearly in the sketch.—*L'Automobile aux Armées.*



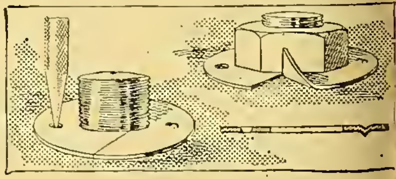
A simple spark gap.

EMPTYING A PETROL TANK.

One occasionally has to empty the tank of a motor cycle, and this is usually a long and tedious job if any quantity of spirit is inside. To speed things up somewhat, unscrew the bulb of the horn and take the cap of the tank. Place the end of the bulb into the opening of the tank, and simple pressure of the bulb will cause the petrol to run out at least twice as fast.—H.D.J.

A LOCK WASHER.

A neat idea for preventing nuts from working loose under vibration has been introduced recently. It consists of a soft iron washer having a slo in one side and a small hole drilled a the same radius as a projecting point o the underside. The washer is place over the bolt end, a centre punch i tapped through the hole, and the washe turned until the projection drops int place in the punched hole underneath The nut having been fully tightened, th slotted part is turned up vertically agains the nut, which is then firmly locked i position.



A simple locking washer.

Occasional Comments

By IXION

Braking Strains.

MR. D. HEATHER, B.Sc., has been lecturing in Coventry on motor car brakes, and several of his points affect motor cycles. He is a reat advocate of fitting brakes to the front wheels f a motor car as well as to the back axle, and gives ie following reasons :

(1.) If you brake only half the available number f wheels, you sacrifice 50% of your potential braking ırface and power.

(2.) A rotating wheel resists lateral tendencies, e., is not so liable to skid as a locked or nearly cked wheel; therefore the ideal brake system slows own one rear wheel and one front wheel on opposite des of the car.

(3.) Driving strains act in the opposite direction braking strains: opposed frictions are, therefore, enerated between the layers of fabric in the rear re casings. Front wheels carry no driving strains, nd front tyres are therefore almost impervious to raking strains.

Applied to Motor Bicycles.

SO far as (1) and (3) are concerned, the arguments apply equally to two-wheeled motors. As regards (2), we all know that a motor cycle kids if its rear wheel is decelerated violently, and iat it skids far more uncontrollably if its front wheel violently braked. Has any reader ever experimented with interconnected front and rear wheel rakes on a two-wheeler, so balanced that the rear heel receives slightly more brake than the front heel? This might prove to be the ideal system. At resent manufacturers are afraid to fit front brakes f any real power, because a skid is inevitable if the ront brake is used alone or used more forcibly than he rear brake—two blunders which a novice is sure perpetrate. Yet the rear wheel brake, used singly, inadequate in real emergencies. In tight corners sudden stoppage always means more or less of a kid, and the skid is corrected and neutralised by a kilful rider, though a dud driver generally tumbles ff. Mr. Heather asserts that 65% of motor accidents re ascribable to the brakes, and in this statement e doubtless includes brake failures as well as skids.

The Ideal Motor Bicycle Brake System.

SEEING that a brake exerts its maximum power when the wheel is just not locked, I presume that the ideal system for a motor bicycle would onsist of interlinked front and rear wheel brakes, perated by a single control, and so balanced that the ear brake was always applied with more force than he front; the system would further be so designed hat it would be quite impossible to lock the front wheel, and that very great pressure would be needed to lock the back wheel. Duplicate control gear would probably be found essential to guard against any derangement of a single control. Such a system will not be easy to design. When we further consider that the system must be proof against the neglect and stupidity of a dud owner, especially with regard to its adjustments, the ideal sounds hardly realisable.

Lower Gears.

LT. DEUCHAR need not have cited me as an apostle of high gears. I think that his suggested figure of 6 to 1 is well on the low side even for a single-cylinder sidecar combination, but it is equally certain that a 4 to 1 top is on the high side for a 3½ h.p. solo. In the days of the dear old belt and the adjustable pulley, each man could be a law to himself in this matter, and one saw knuts with more swank than sense trying to run standard Triumphs with front pulleys as big as bread trenchers. The worst of the modern rigid drives is that any variation in gear ratios has to be allowed for in design, and necessitates quite an expensive set of spares. But I think Lt. Deuchar may rest content. Push bicycle makers always give their customers a choice of gear ratios—often between as many as six series. When the trade settles down, the standard 3½ h.p. will probably be catalogued with three different sets—one for fast solo work, one for general purposes, and the lowest series for heavy sidecar duty. I don't suppose, however, that the starting point of the last series will be as low as the 6 to 1 for which he presses.

When Speed is Pardonable.

THOSE motor cyclists who denounce high road speeds wholesale are probably men whose hours on the road are so limited that every moment in the saddle is a joy to them. Let them extend their sympathy to riders like myself, whose mileage perhaps approaches a quarter of a million. Much as we all love our tight little island, no sane man can deny that considerable patches of its road system are exceedingly dull. At first acquaintance, plus the stimulation of an unwonted ride, it is possible to jog slowly over such stretches, and to enjoy the experience. But when one traverses them for the umpteenth time, they become a bore. These duller patches are often comparatively open and empty of traffic. I know many of them over which a cautious rider can maintain an average very considerably in excess of legal limit for hours together, without endangering himself or anybody else. On such rides experienced men naturally open the throttle, and most of us do a bit of road burning. It does not follow that we are soulless maniacs. Put us in a Devon lane, or on Dartmoor, or round Whitby, or in the Lakes, and we jog along at a miserable potter, with our eyes right off the road.

A ROAD TEST of the MILITARY MATCHLESS

The Russian Government Model as a Passenger Machine.

THE 8 h.p. Military Model Matchless-Jap sidecar combination is a mount which was originally intended for the Russian Government, and was built to suit the ideas of the motor cycle experts of our one-time Ally, with the result that it does not quite meet the views of English connoisseurs in all details. Still, there is not much one can criticise in its design, save the very long magneto chain drive, which, together with the high crank case clearance, are features that render the outfit especially suitable for use in our Overseas Dominions.

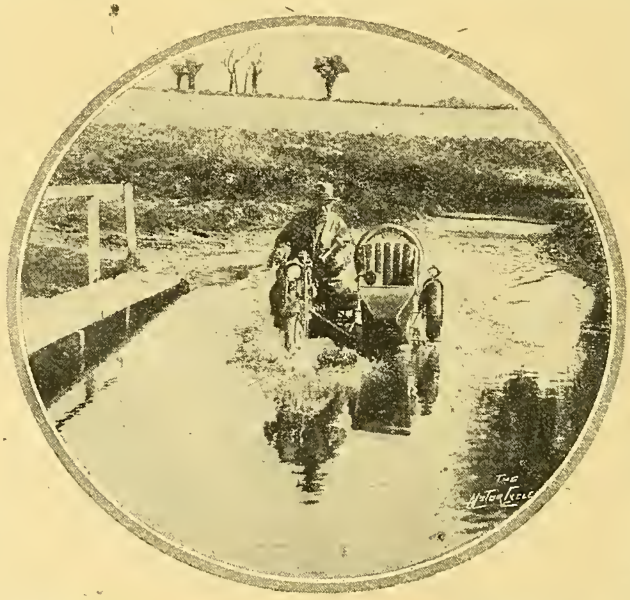
A description of the mechanical features of this machine has already appeared in these pages, but until quite recently we had no opportunity of testing its behaviour on the road. However, as the opportunity did come, we armed ourselves with a special short-period permit and a camera, and gave the combination as good a testing as could be got on a minimum petrol consumption. First of all came a long drive out of London through such traffic as is left in the Metropolis, which was just enough to show that the Matchless was possessed of a very flexible engine which rendered it quite a pleasure to drive in crowded streets. It also showed that Messrs. Collier and Sons, Ltd., had taken the trouble to tune the carburetter carefully, and this, combined with the fact that the inlet unions on the latest type J.A.P. engine are absolutely air-tight, rendered the engine capable of running very slowly. The carburetter was of a pattern which is frequently fitted to motor cycles, but is not by any means automatic, so all the more credit is due to the makers for tuning it so successfully. Still, goes against the grai for the all - roun motorist who ha driven all types of motor vehicl during the last fifteen years to hav to close the air after opening th throttle past the halfway point.

What impressed us most after th flexibility of the machine was i extreme comfort. Furnished with a Brooks saddle, 170, with springs which just suited the rider's weigh and a pair of excellent spring forks, it was difficult t imagine that a spring frame machine could hav afforded greater comfort, and as many who are ab to use a motor cycle at the present time are well awar the roads are in places worse than it was thought i 1914 that English roads could be.

Starting the Engine.

After our journey home, some difficulty was four in starting up the following morning, which was, firs owing to the fact that the driver was unacquainte with the machine, and, secondly, that no compressic taps or priming devices were fitted, since the Russia experts' stipulation of high crank case clearance le no room for these co veniences. To overcon this difficulty we remove one plug and poured a litt petrol first on the pl points and then into tl cylinder. After that tl engine was started, ar when once warm present no further difficulty.

Now, the proper way start the engine of sidecar, which is not well known as it should b is to raise the exhaust val with the right hand ai with the left grip tl luggage carrier. This giv an enormous leverage the kick starter, and t tip when once acquired w enable the largest sidec engines to be start without difficulty, and wi out priming, provided t throttle is only open slightly and the air close



Taking a watersplash comfortably. The high placed magneto and increased crank case clearance enable the Matchless outfit to negotiate the roughest country and to ford fairly deep streams.

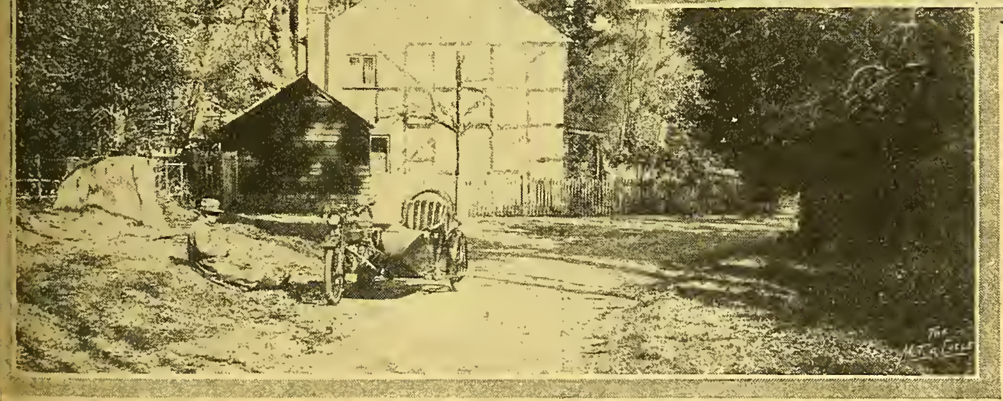
Road Test of the Military Matchless.—

During the test the weather, though brilliantly fine first, became, later, distinctly seasonable. March, is sometimes its wont, went out as it should have ome in—"like a lion"—and "April" showers preominated. This gave plenty of chances of seeing ow the outfit behaved on wet roads, and, though we ere caught in plenty of showers, we never wore leg eralls, and yet the bottoms of our nether garments ere hardly wet and little splashed with mud, so excelntly was the mudguarding carried out. Most of our urneys were along by-roads and well off the beaten ack in search of pretty spots to photograph, which ıtailed slow driving followed by sudden spurts to imb up single figure gradients, nearly all of which ere negotiated on top speed.

The country abounds in watersplashes, and through ıese the machine was taken without hesitation, and, ving to the enclosed chain drive and high placed agneto, they were traversed without the slightest ifficulty, and while the ford was often deep, as is ıown in one of the photographs illustrating this rticle, the rider hardly received a spot of water on is garments.

General Construction.

The machine is strongly constructed throughout, early built to last, and of a quality which a South frican motor cyclist explained to us the other day is ıly to be found in British machines. The Matchless certainly built to stand hard wear and rough usage, and after the war should be ideal as an Overseas model. We naturally drove the machine most of the time it was in our hands, but we did not miss the chance of riding in the sidecar as a passenger, and this we found to be extremely comfortable, even over the roughest roads. Messrs. Collier and Sons themselves admit that this model is not their best, as it was designed for a special purpose, but in our opinion it is a fine machine, especially for Overseas use. We can also speak in the highest terms of the latest J.A.P. engine, which was reasonably silent, and yet quite powerful.



(Top) Near the village of Whitwell. (Bottom) A picturesque scene in the village of Ayot St. Lawrence.

GARAGE CHARGES.

'N the suburbs of most provincial towns there are large numbers of houses renting at about 10s. per week. If one works out the capital involved and he ground area, one must come to the conclusion that ven 2s. per week for garage space for a sidecar comination is too much. It should be possible for an nterprising garage man to build up a big business by letting floor space for one shilling per week. The rider who pays too much rarely buys his supplies from the same garage. If garage rent were low, the rider would be willing to undertake to give the proprietor all his custom, but, as it is, the latter often succeeds in actually driving away other motorists who judge his repair charges by his garaging fees.

Steering and Stability of Single-track Vehicles.

INTERESTING CONCLUSIONS REACHED BY MATHEMATICAL PROOF. Part II.

The following notes on the stability of motor cycles are taken (as promised in our issue for Feb. 14th) from an article, written by Mr. Geo. S. Bower, which appeared in "The Automobile Engineer" for October, 1915. It should be noted that all the statements and conclusions are proved mathematically in the article from which they are taken, and our scientific readers are advised to refer to this article if they wish to pursue the matter further, when they may rest assured of finding much to interest them. We regret that space does not permit of our printing the whole argument.

General Riding Considerations.

In actual practice the rider of a motor cycle progresses in a series of swerves, first in one direction and then in the other, in order to check the constant tendency to fall sideways. The less the amount of swerving required the more comfortable is the machine to ride.

Effect of Vertical Position of Centre of Mass.

It would appear that the height of the centre of gravity of the machine has not so much influence as is generally supposed on its steering qualities. If gyroscopic couples are non-existent, the angle of lean is unaffected by the height of the centre of mass, as also are the values of the road reactions on the two wheels against centrifugal force. The higher the centre of gravity, the greater the amount of inertia of the machine about the ground, and hence the more sluggish it will be in moving in response to the gyroscopic torques used in balancing, for the latter, being dependent on the speeds and masses of the wheels and flywheels, will be approximately the same whether the machine is high or low built. The writer has noticed a motor cycle to steer worse, even on dry roads, when heavy luggage was put on the carrier. This was probably partially due to the fact of the angle of lean being altered from that to which the rider was accustomed. The wobblings to correct errors of judgment thus made would require to be more violent owing to the increased moment of inertia of the machine about the ground. The increased skidding effect due to weight behind has troubled the writer very much, despite what pillion enthusiasts may say to the contrary. Of course, it is *possible* that a very heavy weight behind may squeeze out the liquid mud and so increase the coefficient of friction. One may often notice the dry track left by a tyre on a wet road.

Excessive weight at the front end of the machine (on the handle-bars) has a very bad effect for two reasons. Firstly, it increases the moment of inertia of the front wheel system, and thus renders it more difficult to wobble the front wheel quickly to maintain balance. Secondly, it increases the centrifugal force reaction on the front tyre, and thus increases the tendency of the front wheel to side-slip—a thing to be avoided at all costs. Dropped handle-bars bring the centre of mass of the rider rather lower and more forward, and hence conduce to easier steering and less skidding.

Recovery from a Side-slip.

When a bicycle skids under the influence of the centrifugal force the angle of lean increases, and, if not reduced, the cycle will fall on its side. Now to bring it up vertical again, one instinctively steers towards the side of falling. This increases the centrifugal force, and hence the tendency to side-slip, so that it would appear to be impossible to recover from a skid except by the use of the feet. When we consider the gyroscopic couples due to the rotating parts of the engine, however, we are led to another, and, the author believes, a hitherto unknown method of recovering equilibrium.

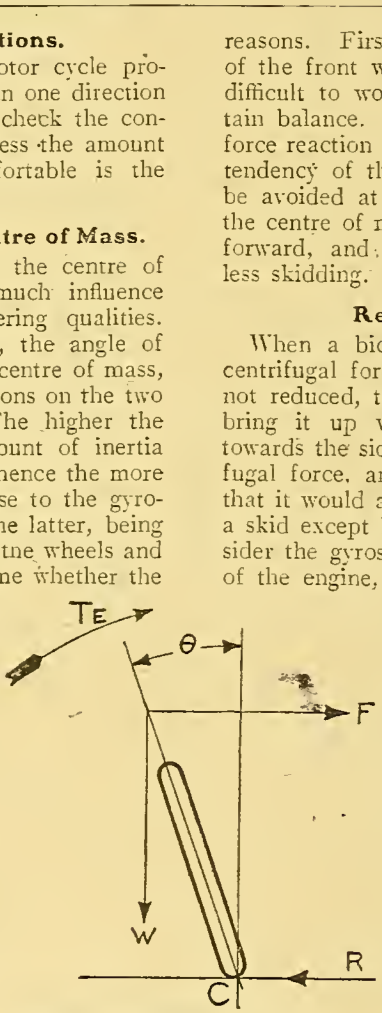


Diagram representing an end view of a motor cycle in motion.

Let the sketch represent an end view of the cycle, looking in the direction of motion. Imagine that as a left-hand turn is being taken, the coefficient of friction between the wheels and ground suddenly decreases in amount. Owing to F not being balanced by the road frictional reaction R, the wheel will slip to the right, thus causing the centre of mass of the bicycle to move in a circle of larger radius, such that F will equilibriate R (R will also increase with the velocity of side-slip). Now just before the instant at which this occurred, the centrifugal force F, together with the gyroscopic torque TE equilibrated the moment of W about C. When slip occurs, however, F is opposed by the resistance to acceleration of the centre of gravity of the machine, the difference between the new resultan

Easy Starting
Under All Conditions

"The other night the bike was left out from 12 a.m. to 8 a.m. in a blinding rain storm. When I got to her in the morning she started up with the first kick."

Mr Just Perfect helps to 'Carry on'

Mr Just-Perfect Helps

Pedley Tyres and Belts are capable of a mileage astonishing to the users of other makes.

Eleven thousand eight hundred miles on a 6-h.p. heavy sidecar combination is the performance that carries proof.

This is the kind of service at your disposal in Pedley Tyres and Belts. They justify their cost many times over, and they help the rider to "carry on" under the worst conditions.

—to 'Carry on'.

Copy of Letter received from Jas. C. Stewart, Inverness, dated 28th Sept., 1917.

"I have gone carefully into the matter of mileage of your 3-inch grooved 1913 Pedley Tyre, and find that the figure is not less than 11,800 miles, of which at least 7,000 has been on the driving wheel, and the balance on the front wheel.

"My outfit is a 6 h.p. Clyno combination with a heavy Millford tandem two-seated sidecar in which I carry two children and an adult. The total human freight on the whole outfit is about 30 stones. This heavy sidecar has been attached all the time except 1913, and my total mileage solo would not exceed 250 miles."

The Performance that carries Proof.

J. PEDLEY & SON, LTD., OXFORD WORKS, GREAT CHARLES STREET, BIRMINGHAM.
LONDON ADDRESS: 30, HOLYWELL LANE, GREAT EASTERN STREET, LONDON, E.C. 2.

eering and Stability of Single-track Vehicles.—

and the old one being equal to the reduction the road friction reaction on the wheel. Thus TE remains constant, the moment of W about C ill bring the machine over on its left-hand side, this eing, of course, what happens in practice (when a ft-hand turn is being taken). Suppose now that the achine is provided with a handle-bar-controlled lutch, and that on the first sign of slip the rider opens e throttle and declutches, allowing the engine to ce, then the gyroscopic torque TE will be greatly creased, and the bicycle will be able to regain its ngular equilibrium about C. Not only this, but the udden acceleration of the flywheel will necessitate a eaction on the frame which will tend to press the ar wheel (which is probably the offender) more rmly on the ground. Of course, if this is overdone e front wheel will skid, and the idea requires to be bmitted to the test of practical experience.

The clutch on the author's machine is not h.b.c., nd he also feels a disinclination for experimental ork on the subject of skidding. Perhaps some nselfish person will take up the work.

Tail Wagging.

This unpleasant phenomenon appears to be due to e variability of the engine torque. At each peak f the engine torque curve the pull on the rear wheel such that it slips slightly in a circumferential direc- on. This, as is well known, greatly facilitates slip- ing in a sideways direction, but before the cycle has ipped far the torque has dropped in value, and the der is able to bring the bicycle straight again by a ight movement of the front wheel.

The liability to "tail wag" is increased by the use f a high gear, which reduces the engine speed, and hence the flywheel effect; by a heavy weight behind, which increases the centrifugal reaction on the rear wheel, and by the use of a rigid drive or a very tight belt, which increases the circumferential slip of the rear wheel.

Auto-stability.

By this is meant the property which may be possessed by a cycle of being ridden without the rider touching the handle-bars or moving his body. The subject is one of some complexity, and has not, as yet, been completely investigated by the author. The results will now be given of a mathematical investigation of the "free" motion of an assumed form of bicycle, consisting of a number of isolated masses, and having a vertical steering pillar. It was found that the offset or "castoring" of the front wheel in relation to the steering pillar is most important in its effects on stability, thus bearing out the general opinion on this subject.

If the machine is travelling too slowly to be stable in itself it may still be ridden without touching the handle-bars if the rider moves his body in the correct manner. The connection between the rider and the handle-bars is now a gyroscopic one, instead of being direct. Suppose, for instance, the bicycle begins to fall towards the left, and that the rider instantly leans to the right (an instinctive action). As previously mentioned, the bicycle will lean still more to the left, in order to keep the centre of mass of the machine and rider unmoved. This motion of the bicycle to the left of the vertical constitutes forced precession of the front wheel, and an examination of the directions of the torques shows that the front wheel will turn to the left. This is, of course, the direction required to counteract falling to the left.

One of the Tanks moving up to assist in holding back the Germans during the recent offensive. The Tank played an important and vital part in our defence.

Three Wheelers.

Several firms well known in the motor cycle world have three-wheel runabouts under way for after the war.

The Motor Cycle in Fiction.

While one daring short story writer has introduced the sidecar combination in magazine fiction, we have not yet come across a novel in which the motor cycle takes a leading part.

The Paper Shortage.

Owing to the serious shortage in the supply of paper, efforts are being made by the authorities to prevent wastage, and any of our readers who come across instances of waste of paper are requested to communicate by letter with the Paper Controller, 23, Buckingham Gate, London.

Sidecar Ambulance Work at the Front.

The French Red Cross are in urgent need of voluntary motor ambulance drivers. The magnificent work these convoys are doing needs no elaboration. It must be realised by every man. All applicants have to be ineligible for active service, or at any rate in very low grades. They, however, must be sufficiently robust to be able to stand open air life, and, at times, periods of considerable pressure of work under trying circumstances. Applications should be made to the French Red Cross, 9, Knightsbridge, Hyde Park Corner, S.W.1.

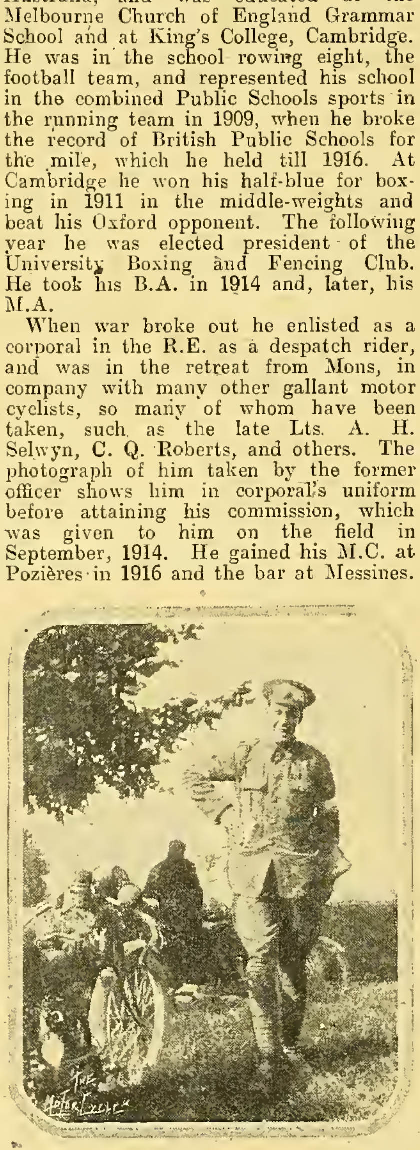
The N.M.C.F.U.

The press secretary of the National Motor Cyclists' Fuel Union, in a contribution to a contemporary, refers to our impressions of a recent meeting of this body which we published in our issue of April 4th. He terms our remarks a misconception of the aims of the Union, which, he claims, is composed of patriots, and that it was unfair for us to suggest unpatriotism on the part of the members. This writer admits that he did not attend the meeting in question. We did attend, and faithfully recorded our impressions, based upon the general tone of the meeting and the remarks of the chief speakers.

Death of a Gallant Despatch Rider.

It is sad to have to record that so fine a motor cyclist as Capt. Ronald Guy Larking, M.C. (and bar), R.E., one of the original B.E.F. despatch riders, was killed in a motor cycle accident abroad. Capt. Larking hailed originally from Australia, and was educated at the Melbourne Church of England Grammar School and at King's College, Cambridge. He was in the school rowing eight, the football team, and represented his school in the combined Public Schools sports in the running team in 1909, when he broke the record of British Public Schools for the mile, which he held till 1916. At Cambridge he won his half-blue for boxing in 1911 in the middle-weights and beat his Oxford opponent. The following year he was elected president of the University Boxing and Fencing Club. He took his B.A. in 1914 and, later, his M.A.

When war broke out he enlisted as a corporal in the R.E. as a despatch rider, and was in the retreat from Mons, in company with many other gallant motor cyclists, so many of whom have been taken, such as the late Lts. A. H. Selwyn, C. Q. Roberts, and others. The photograph of him taken by the former officer shows him in corporal's uniform before attaining his commission, which was given to him on the field in September, 1914. He gained his M.C. at Pozières in 1916 and the bar at Messines.



Capt. Ronald Guy Larking, M.C. (and bar), R.E. who was recently killed in a motor cycle accident.

Special Features.

STEERING AND STABILITY.

NEW U.S.A. ARMY ENGINE.

CHAIN GUARDS.

The Internal Combustion Turbine.

The problem of the internal combust turbine continues to attract motor e neers. We have seen many interest experiments, including a turbine actu in motion, but its fuel consumption out of all proportion to the po developed.

Friction Drive for Motor Cycles.

Several inventors in the past h experimented with friction-driven mo cycles, and, in face of the success the G.W.K. light car, there seems ev promise of ultimate success. Such "gear" offers certain advantages, am which may be mentioned comparat silence, simplicity and low cost.

Sale of Unclaimed S.E.R. Motor Cycle.

Included in the annual auction sale S.E. Railway "unclaimed" prope advertised to take place on April 2 at Holborn Viaduct Hotel is an unkno and nameless motor cycle. No parti lars are given, but a line of raised t is given to this lot. One can understa tyres or motor accessories being l behind after a S.E. Railway journey.

Is it a "War-worn?"

The sale should be worth a visit, only to see this single "unclaime motor cycle. A stolen mount, perha with a history attached, or a return war-worn for the dump that forme existed alongside a S.E. Railway goo siding that perhaps became lost or w astray in transit.

German Atrocities.

An inhabitant of San José, Californ enlisted in the French Army in 1914, a took part in some of the greatest batt in the early part of the war. After t Verdun campaign he became a despat rider on account of his knowledge motor cycles. While on his mount was frequently within, or even behi the German lines, and being now ho on leave he insists that none of the stor prevalent in America concerning Germ cruelty is equal to the actual trut While riding at the back of the Boc lines, as is possible sometimes when t warfare is in the open, he says he often stopped to bind up the bleedi arms of tiny children who have be deliberately maimed for life. This you American, Henry Richer, rides an Indi motor cycle.

Ex-motor Cyclists.

Many old-time competition riders have oined the Air Service "for good," they ay.

oy Sticks.

We anticipate, after the war, quite a number of attempts to embody the prin-iples of the joy-stick control to motor ycles.

The Twin Two-stroke.

At one time designers of twin two-trokes appeared to have been so dis-ouraged that the future of the type was very uncertain. There are now several win engines which promise to fulfil heir designers' expectations, and which include the flat, V and vertical types.

After the War?

We are now frequently receiving a query that we must admit outright we annot answer: "When peace is declared, shall I be able to use my machine at once, or will there e restrictions in force for some ime?"

To these anxious enquirers we enerally reply that, as we have ot yet been informed of the con-itions of peace, we must regret-ully confess our inability to answer the question, but that we eel fairly safe in informing the nquirer that the Defence of the Realm Act will most probably remain in force until it is repealed.

eace and Plenty?

In our opinion, the only way to nsure anything like peace and lenty for the motorist within a reasonable time after the coming f peace is by means of that controversial liquid—alcohol. As far s present indications go, this is the only fuel that will ever be ermanently available in unlimited uantities for this country, and, if t has to come, surely the sooner the better. There is no doubt that petrol will be extremely scarce for many a long day, and it is rather nnoying to think we have an lmost unlimited supply of fuel eld up entirely by antiquated Government restrictions on its sale—restrictions, of course, in no way connected with its use by motorists *as such.*

A Knock.

Is there anything more painful to the expert motor cyclist than to see a smiling self-satisfied novice deaf to the knocking of his engine? Every rider was a novice once, but every novice should know when an engine knocks.

The Designers of the U.S.A. Standard Motor Cycle Engine.

The designers of the U.S.A Army standard motor cycle engine, described elsewhere in this issue, are gentlemen whose names are fairly well-known to English motor cyclists—Mr. William S. Harley of the Harley-Davidson Co., Mr. Oscar Hedstrom of the Hendee Mfg. Co., Mr. Frank Schwinn of Chicago, and Capt. F. C. Hecox, representing the Army. We believe that actually Mr. Hedstrom has been for a large portion of the time replaced in the work by Mr. Charles Franklin.

Noises.

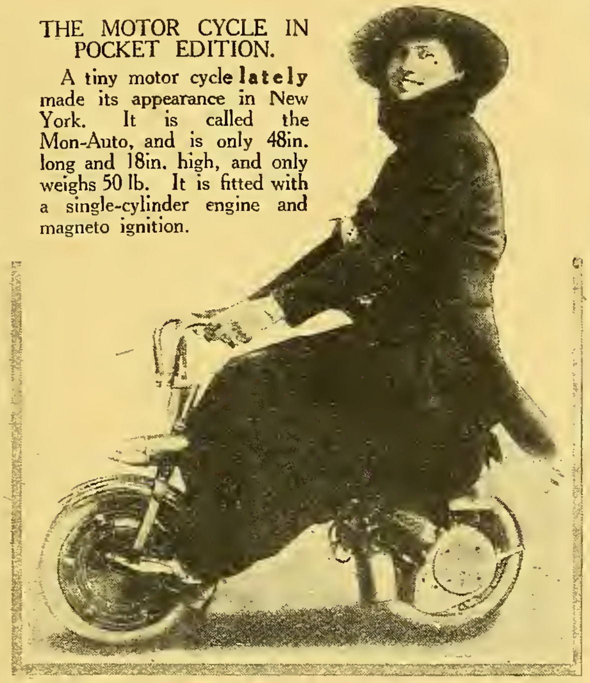
Many things about a motor cycle tend to magnify sounds—air-cooled cylinders and tubular frames being the chief offenders in this respect.

Garaging.

One of the greatest problems to be faced when motor cycling becomes normal again is the question of garaging. Already little groups of motorists in the provinces are making plans to build co-operative garages in which to store and repair their machines.

Expensive Gadgets.

When one considers that some automobilists pay over £1,000 for a car, and equip it with an "all four wheels" jack costing about £50, and a Gabriel horn absorbing another £40, one realises the value to be obtained with a good motor cycle.



THE MOTOR CYCLE IN POCKET EDITION.

A tiny motor cycle lately made its appearance in New York. It is called the Mon-Auto, and is only 48in. long and 18in. high, and only weighs 50 lb. It is fitted with a single-cylinder engine and magneto ignition.

The Humphris Gear.

At least three firms have recently experimented with the Humphris gear, of which the Quadrant and Rex were two. Shall we see motor cycles embodying this interesting patent in the near future?

Oil from Home Sources.

A committee has been appointed to advise to what extent and within what time it should be possible to carry out the proposals of the Petroleum Research Department on the production of fuel oil from home sources.

The King in a Tank.

During the King's visit to Lincoln he expressed a desire to make an excursion in a Tank. "This is my fourth adventure in a Tank," said the King to the officer in charge, "and I want you to take me over the most awkward places." Having been taken over the roughest places the officer could negotiate, His Majesty seemed well pleased with the experience.

The Big Single.

Present tendencies indicate that the very big single of over 700 c.c. will be very uncommon in post-war buyers' guides.

Racing on the Sands.

At North Brighton (N.Z.), in November last, a forty-mile solo race was run by the Pioneer Club (Christchurch). The event was won in 39m. 53s.—*i.e.*, at over a mile per minute—by R. L. Kennett. *Wheeling* of New Zealand, from which paper we take the information of the event, while commenting on the winner's fine riding, says nothing of the machine he rode, not even its make, and yet this paper is the organ of the N.Z.A.C.U.!

The Ladies of Pervyse.

Those two gallant ladies, the Baroness de T'Serclaes and Miss Marie Chisholm, who have done such devoted work for the Red Cross with the Belgian Army in the firing line throughout the war, and who have often been referred to in these pages, have, we regret to say, been badly gassed. It may be remembered that they are both skilful riders of Douglas motor bicycles, which they have used for several years at the Front.

In the early hours of March 17th, during a heavy bombardment, a gas shell burst on the door of their dug-out and blew it in. As there had been no warning of the attack, the two ladies were not wearing gas masks, and consequently are very badly affected.

Both ladies are members of the British Red Cross Society, have received the Order of Leopold, the British Military Medal, and the Royal Order of Elizabeth for bravery and life-saving under fire.

Quick Work.

We know of a middle-aged gentleman who joined the R.N.A.S. as a mechanic, learned "all about" aero engines in a week, and designed an internal combustion turbine for aeroplanes by the end of his first month. Why does every novice fly to internal combustion turbines? The best brains in the automotive world have been devoted to this problem, and we are still using cylinders and pistons.

Bore-stroke Ratio.

Automobile engineers appear to agree that the small bore long stroke engine is the best form of internal combustion motor for high speed vehicles. Some car engines have a stroke over twice the dimensions of the bore, yet motor cycle engines are mostly "square." Why?

Inventive Activity in New Zealand.

We recently stated that the fuel doping craze was afoot in the Antipodes. The latest in this line is the announcement that a flux has been perfected and placed on the market which will braze any metal, including cast iron. We should be glad of an opportunity of experimenting ourselves, but are afraid the chance of realising the hope is somewhat remote.

MILITARY NOTES.

Corroboration of an Extraordinary Story. An Unofficial Badge.

COST OF THE WAR FOR RUSSIA.

IT is estimated in Petrograd that the total cost of the war for Russia is 50,599,275,699 roubles, or about £5,059,927,569.

* * *

THE CROIX DE GUERRE.

IN the issue of the 21st March we referred to Lt. D. S. Baddeley, A.S.C., Croix de Guerre, as having been the former treasurer of the Motor Cycling Club. This was not so, as the post was held by his brother, Capt. L. A. Baddeley. D. S. Baddeley, however, was a well-known rider before the war, and an energetic member of the M.C.C.

* * *

CORROBORATION.

WE have received from Capt. A. R. Jordan, R.A.M.C. (France), the following letter, which may settle any doubts in the minds of those who disbelieved the remarkable story of Pte. Taylor, whose adventure we mentioned recently:

"I was interested to read in your last issue to reach us a paragraph relating to the extraordinary case of Pte. Taylor, D.C.M., of the London Regiment, who 'lay out' wounded for over six weeks last summer.

"The man was a patient under my care, and you can assure your French readers that the story is perfectly true, and if they want further details put them in communication with me.

"Taylor arrived here looking like Robinson Crusoe, with long dark hair and beard, emaciated, and with deeply sunburnt skin. He had a recently healed compound fracture of the femur, which had completely healed in the six weeks without a splint.

"He told us the story of how he had lived on dead men's rations until he could crawl, and on nothing but bully beef and water for the last fortnight, and of how his companion, who tended him during the first week when he was delirious, was ultimately captured.

"The whole thing was so incredible that it was carefully enquired into, in connection with the award, while he was here, and there is no doubt of its truth.

"I think his case deserves publicity, as we warned him at the time his adventure was so extraordinary that it would be difficult to get people to believe it."

* * *

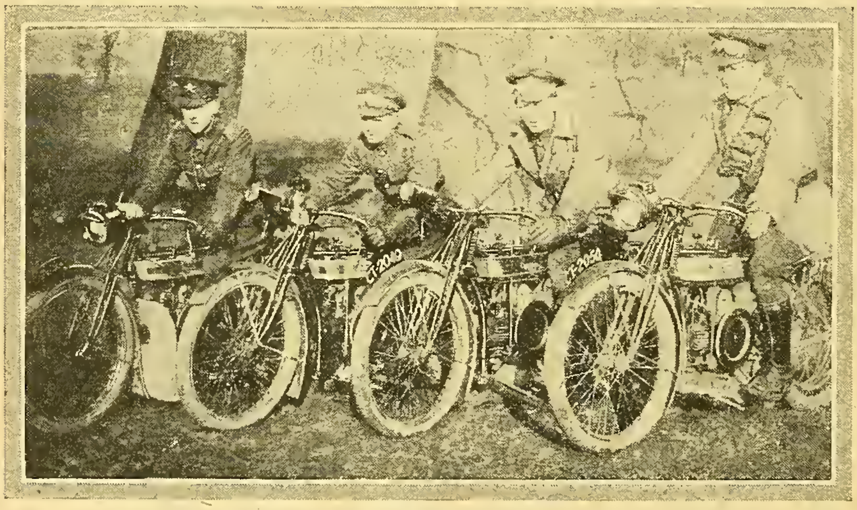
THE P. AND M. IN FRANCE.

AIR-MECH. T. P. DIXON, R.F.C., writes from France respecting the way his P. and M. stands up to its work: "It smiles at the hills, never asks to be shut off, and delights in ticking over. I am just off on a 150 km. run, and hope the little 'bus will behave itself. It is raining like anything, so please pity the poor R.F.C. D.R.'s. They are just doing their bit."

* * *

A GALLANT MOTOR CYCLIST AIRMAN.

ONE of our greatest airmen, Capt. John L. Trollope, R.F.C., has unfortunately been posted missing during the week-end. In what he describes as "the most wonderful day of my life" he created a record by destroying six enemy machines. This was on March 21st, the day that the Germans first launched their offensive against the British lines. One machine was shot to pieces, the second one went down in flames, the third was forced down into a spin and was seen to crash, the fourth exploded in mid-air and fell down in fragments, while the fifth and sixth, flying quite low down, were attacked together and both crashed. Capt. Trollope, who is only twenty years of age, was a despatch rider in France during 1915, and only took up flying in the autumn of 1916. He was an old Malvernian, and left school to join the Army.



Scouts of a M.M.G. battery mounted on Douglas motor cycles.

PROMOTION FOR AN IRISH MOTOR CYCLIST.

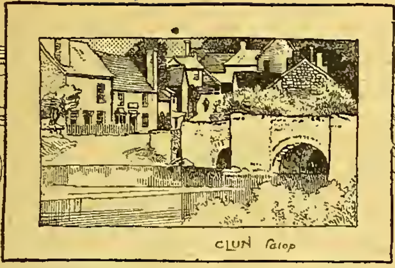
J. A. H. WATERS, one of the membe of the Dublin and District Mot Cycle Club, who has been servi on the Western Front since the ear days of the war, has been appoint major. In pre-war days, Waters was well-known figure in competition mot cycle circles in Ireland; and at Portma nock, in the speed trials on the sand and in reliability events on the road, h steered many a lightweight to victory He joined up in the early months o the war, being granted a commission i the Mechanical Transport Section of th Army Service Corps, and was appointe a captain after being about twelv months on active service. He has spen the whole of his time in France, fo the most part serving the guns wit ammunition, and in his new capacit will be the officer commanding the 33r Division M.T. Company.

Major J. A. H. Waters, A.S.C.,M.T., of the Dublin and District Motor Cycle Club.

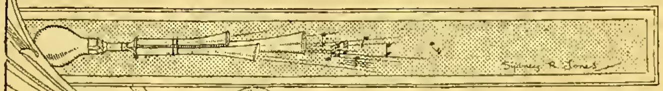
* * *

AN R.E. UNOFFICIAL BADGE.

IN an article which appeared in th issue of March 14th, entitled "Th D.R. through French Spectacles," mention was made of a badge worn b certain despatch riders, consisting of winged wheel and the initials "D.R." We are informed by the Commandant o an important R.E. Centre that the badg is not an official one, and that the wear ing of it is irregular. It is believed t have originated with certain Territoria Force Units, and the wearing of it i not universally permitted.



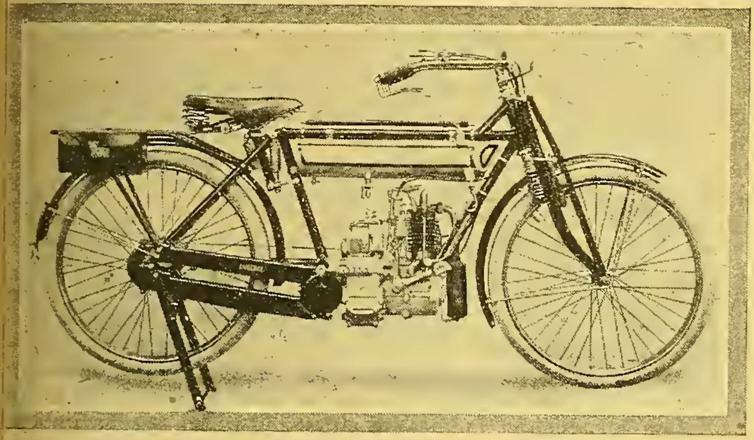
THE CHAIN GUARD.



NOTES ON A DEBATABLE SUBJECT.

SINCE it is certain that chain transmission will be almost general practice on passenger motor cycles in the immediate future, the question of hain guard design is one of paramount importance.

Many British designers have attempted to solve this roblem, and in many cases considerable success has een achieved, but there are very few owners of British hain-driven machines who claim that the chain guard s everything that can be desired. Concerning merican machines, we hear fewer complaints on this core, for the very good reason that the Americans o not appear to have attempted to enclose the chains ompletely.



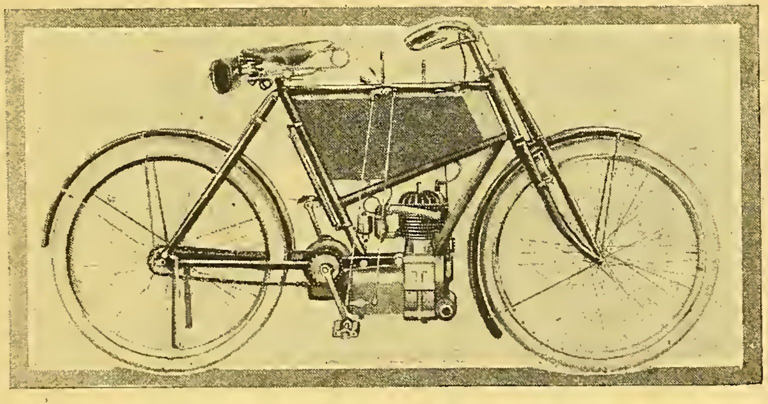
The Arielette lightweight of 1910, a design in advance of its time. Note the neat chain case, which was of aluminium.

From a mechanical point of view it is highly esirable that the chains be protected from mud, rit, and rain. To run a chain exposed is deliberate estruction of a very delicate and accurate iece of mechanism. One has only to ealise what even a small fraction of an nch wear at all the points of contact neans to appreciate this. If one examines link of chain or the parts thereof it ecomes apparent how easy it is for dust o wear the many bearing surfaces. The hain guard, therefore, is very important, nd deserves more attention from the designer, who, in many cases, appears to ave left the problem to the tinsmith.

It occurs to the writer that one solution of the problem is so to design the machine that the necessity for the chain to cross the chain stay of the frame is eliminated. One has only to examine a machine like the American Henderson to see how simple it would be to fit an oil bath chain case to this machine if the clearances permitted it. Hence the necessity to consider the chain case as part of the design, and not as an after-thought in the same category as the saddle and the carrier.

Probably the neatest chain casing I have seen was the method employed by an American cycle car concern. The chains were enclosed in cork-lined tubes, which connected two circular boxes containing the sprockets. One cannot imagine the system being very durable, however, but there appears to be no reason why chain cases should not be kept as small as possible. If sprockets of equal size were used this could be done quite easily; but, of course, all the gear reduction would have to be made in the primary drive. This would be an advantage in other directions. In the first place the rear chain would be working at a lower speed, and, secondly, it would assist designers to overcome transmission troubles connected with spring frames. A slower rear chain would be more silent, but since most of the chain noises emanate from the first chain, this advantage would not be so apparent unless the primary drive were by shaft or by silent chain running in a well-made oil bath case. The guarding of the front chain is not a difficult matter, and eventually we may have the engine and gear box as a combined unit.

The small rear chain case also has the advantage of a neater appearance, as will be seen from one of the illustrations reproduced here. Incidentally, the Arielette design is one of the most interesting little machines introduced to the wheel world. It embodies a three-speed epicyclic gear unit integral with the



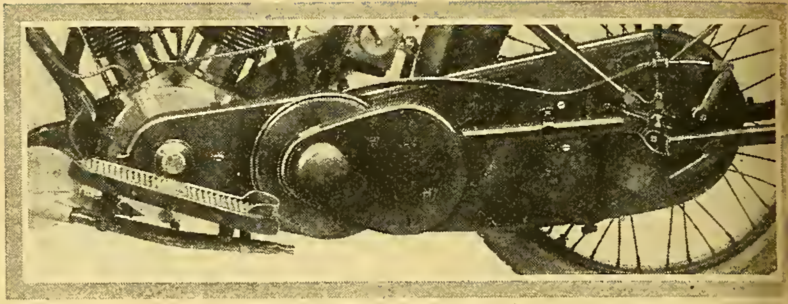
A 1904 Swift with 1-1 chain ratio, the prototype of the Arielette.

The Chain Guard.—

engine, and resembles, in many ways, the little Swift of 1904.

The large chain guard, to be successful, must be made from much heavier metal than a smaller one, while an aluminium casting probably is the best for both small and large cases. The case on the Arielette comes nearest to the tubular chain guard to which I refer, and it shows that the value of the small case was appreciated by the early advocates of chain drive.

VEDETTE.



A modern chain case arrangement.

Research Association of Cycle & Motor Cycle Trades

The Point of View of the Cycle and Motor Cycle Manufacturers' and Traders' Union.

IN recent issues we dealt editorially with the Government scheme for the encouragement of industrial research. Briefly, the Government have set aside a million pounds for that purpose, and each industry is entitled to apply for financial assistance the extent of which, we understand, will be determined by the amount of money the industry itself is prepared to expend. The Trade would have control of its own Research Association subject to a certain degree of Government supervision.

A Research Association for the Cycle and Motor Cycle Trades is in process of formation by the Cycle and Motor Cycle Manufacturers' and Traders' Union, Ltd. The Union has voted from its accumulated funds the sum of £2,500, and has appealed with some degree of success to its 250 members for subscriptions and donations. The Union has had the matter in hand for the last twelve months, and the time has now arrived for the scheme to be definitely shaped.

In the meanwhile, the motor car trade has a Research Association in contemplation, and discussion naturally arises as to whether a joint association of the cycle, motor cycle, and motor car trades would best meet the situation. However, while the interests of the two industries are the same up to a point, that point is soon reached, and is, in fact, passed before the important item of frame design is considered.

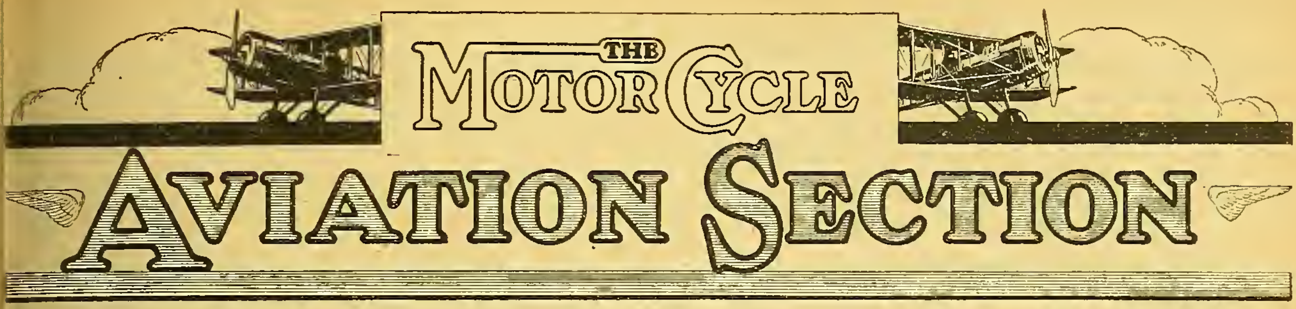
The Union has tentatively made quite satisfactory arrangements to co-operate with the Birmingham University, and the prevailing opinion is that the Union can better serve the purpose of its particular interests by adhering to those arrangements than by co-operation with the motor car trades.

We understand that Sir Oliver Lodge, the Princip of the University, is prepared on certain conditio to place the vast resources of the University at th services of motor cycle research investigators. Mor over, co-ordination with the Birmingham Universit carries with it immediate use of laboratories ar equipment, as well as trained investigators in eve branch of engineering, which in the case of a separa association would take years to establish, and whe established could only be maintained at enormou cost. The offer by the Birmingham University t place its engineering resources at the service of cyc and motor cycle research seems to be too good to l neglected, and it has the further advantage that r difference of opinion can arise as to the direction investigation, which might easily happen if the interes of two trades were attempted in the one institution.

We learn that certain members of the Union, bo firms and individuals, have not yet shown any pra tical interest in the scheme, but we are confident believing this is due to their not having given th matter consideration. Surely, by this time there no one, either directly or indirectly, interested in tl industry who does not recognise the imperative nece sity for the closest scientific research to be applied the improvement of the motor cycle, and inasmuch the cost of such research work cannot be undertak without the united support of the whole trade, we a hoping that every motor cycle manufacturer, comp nent, and accessory and tyre manufacturer will cor forward with his membership subscription and don tion without delay and so take his share in an unde taking likely to have such far-reaching consequence

INITIATING THE NOVICE.

THE Rochester (U.S.A.) agents for Harley-Davidson motor cycles have hit upon a useful plan to popularise motor cycling. During the riding season they have a school open to all who ride and intend to ride motor cycles. Last year the classes were attended by an average of a hundred riders, and grew more popular every week. One evening is devoted to each of the important parts of a motor cycle, such as the carburetter, magneto, transmission, etc., etc., and, provided the lectures were not too technical and also not too elementary, we think such classes would be very popular in this country. One gentleman our acquaintance, who is interested in the boy sc movement, is utilising his idle light car and stud motor cycles to teach an automobile class of b scouts, and no doubt much good will come of efforts. We have also heard of a motorist scho master who holds a weekly evening class on mo mechanics which is very popular with his pupils, whi prior to the war, a North of England motor ag built a special "club" room adjacent to his gara where was held a weekly round table conference.



THE MOTOR CYCLE AVIATION SECTION

The enormous importance of the Air Service needs no emphasis: it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouraging of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

Ten Years Ago.

On December 31st, 1908, Wilbur Wright flew 77½ miles in 2h. 20m. 23s. at Le Mans, France.

◆

3½ h.p. Aeroplanes.

According to an authority on aviation, there seems no valid reason why flight should not ultimately be achieved with a 3 h.p. or 4 h.p. engine.

◆

A Scotch Aviator in Russia.

Mr. Chessborough J. H. Mackenzie Kennedy is a Scotchman better known in Russia than in the land of his birth. To him the development of the aeroplane in Russia was largely due. The last ten years of his life are a romance which should make more than one chapter in the history of aviation when it comes to be written. In Russia Mr. Kennedy was known as the "Jeweller of Aviation," and was a close friend of the famous Sikorsky.

Box Kites.

The box kite was invented thousands of years ago by the Chinese.

◆

The Prototype of the Zeppelin.

In the late eighties, Capt. Kostovitch, of the Russian merchant marine service, built a rigid dirigible, which may be regarded as the prototype of the Zeppelin. Count Zeppelin unquestionably was aware of Kostovitch's experiments when he began the construction of his own gigantic airships.

◆

P. and M.'s and Douglases.

The Royal Air Force is gradually making itself felt in many little ways if not in big ones. For instance, three P. and M.'s recently arrived at the garage of a big R.N.A.S. airship station in the North, and we all know that up till now P. and M.'s had been used exclusively by the R.F.C., the R.N.A.S. favouring the Douglas.

The First Cross-Channel Flight.

Monsieur L. Blériot flew from Calais to Dover on July 25th, 1909.

◆

The First to Loop the Loop.

Kostin, a Russian, was the first airman to loop the loop. Kostin used a Henry Farman machine, and the attempt was made without design. He was trying the machine, when he was struck by a side gust of wind, which would certainly have turned him over had he not been an expert flying man. To escape disaster he made a "false loop," and finding that the machine could fly in that position, he twice repeated the same manœuvre, in which the machine was so nearly upside down that the aviator was sprinkled with petrol. This happened several months before the famous Frenchman, Pegoud, startled the world with his exhibition flying. How many discoveries of this type have not been due in some measure to accident.

THE ROYAL AIR FORCE: OPENING FOR BOYS.

THE Royal Air Force will be open to receive boys from time to time, for long service only, between the ages of fifteen and seventeen years.

PERIOD.

(*a*) Eight years with the Colours, including period served prior to attaining the age of eighteen years, and four years on the Reserve.

(*b*) Six months before the termination of eight years' service with the Colours they may, if recommended by their Commanding Officer and Air Ministry authority is given, re-engage to complete their Colour Service to qualify for pension.

RATE OF PAY.

1s. per diem with free kit, food, etc., and war pay at 1d. a day for each year of service rendered during the war, subject to good conduct. On attaining the age of eighteen years boys will be appointed third-class air mechanics at 2s. per diem.

TECHNICAL TRAINING.

Boys will have an opportunity of learning a trade, which should be useful to them on their discharge.

All boys have to attend Divine Service at least once each week.

Boys are housed together under specially-selected disciplinary non-commissioned officers.

The regular working hours for boys do not exceed forty-eight hours per week. In the case of boys under seventeen they do not exceed forty hours per week.

Systematic arrangements are made for the boys' education, recreation, and amusements

MEDICAL CLASSIFICATION

Grade 1 only.

Applications for enlistment should be made by letter, stating full particulars, including trade (if any). The following certificates will be required:

1. Written consent of parents or guardians, duly witnessed.
2. Certificate of good moral character from clergyman.
3. Certificate of birth.
4. Certificate of schoolmaster of having passed Standard VI., or equivalent.

Applications should be made to the Royal Air Force Reception Depôt nearest to the residence or place of registration of the applicant.

Applicants must be natural born British subjects and the sons of natural born British subjects.

FLYING FACTS AND THEORIES.

CONTROL. (I) CLIMBING.

By W. G. Aston, A.M.I.A.E.

THE climbing abilities of an aeroplane depend directly upon the excess of power which the engine possesses over and above that which is required to sustain the machine in normal horizontal flight. Generally speaking, climb is quite independent of such control as is effected by moving subsidiary planes, and is dictated by throttle opening only. In fig. 1 a horizontal flight path of a machine is represented by the line AB. In these circumstances we will suppose that 60 h.p. is required from a motor which is capable of 100 h.p., and that the speed is 60 m.p.h. Now if the motor is opened out to its full capacity and the setting of the tail planes not altered, the immediate effect will be—first an increase in speed due to the enhanced thrust that has become available, and secondly, an increase in altitude due to the fact that, keeping the angle of incidence constant, more air is accelerated downwards in a unit of time, and therefore there is an increase in the lift force. Whilst flying level with 60 h.p. the lift is exactly equal and opposite to the weight of the aeroplane; with the extra speed provided by the addition of 40 h.p. the lift is greater than the weight, and therefore the machine climbs along the path indicated as AC. If still more power were available it would follow the still more sharply inclined upward path AD.

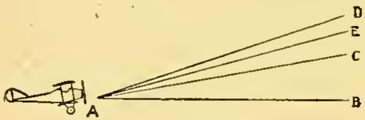


Fig. 1.

Now, as I have before pointed out in these articles, kinetic energy can always be transformed into potential; in other words, speed can be exchanged for height. Since the original speed has been increased, it follows that by dropping this extra velocity more power will be released for climbing purposes. This is effected by means of the elevator control. The pilot increases the angle of attack of the main planes by negatively inclining his elevator, with the result that more air is dealt with by them, and the speed is reduced once more to 60 m.p.h. Since for this speed 60 h.p. only was required for horizontal flight, it follows that 40 h.p. is available for direct lift, and in these circumstances the climb, that is to say the maximum climb, will be along the line AE, on the assumption that the original 60 h.p. represents the minimum power required for horizontal flight. If such minimum power is less, then there is more power still that can be applied to the acquisition of altitude.

The Best Climbing Speed.

It needs to be pointed out that like most broad generalities this statement is only more or less true, and needs to be qualified by the fact that, although in the greater number of aeroplanes the best climbing speed is round and about the minimum speed of the machine, it does not follow that such is necessarily always the case, owing to the fact that since the angle of incidence has been changed, the ratio of lift to drag has also changed. This sometimes leads to the result that the best climbing speed is a little higher than the minimum horizontal flying speed, but it is only rarely that there is a big discrepancy between these figures, though it is more likely to occur when the design has been laid out primarily for the object of providing the best performance at a big altitude rather than near the ground.

Returning to the hypothetical aeroplane, already dealt with, it is easy, knowing these figures, to calculate what the climb will be. If 60 h.p. only is required for flying level, 40 h.p. is available for direct lift. If the machine weighs 2,000 lb. the climb will be at the rate of $40 \times 550 \div 2{,}000$ feet per second —*i.e.*, 11 feet per second, or 660 feet per minute. This, however, will only be the case whilst the engine is giving full power.

As I showed in a previous article, power falls off as altitude is increased, hence the rate of climb also falls off, until when the aeroplane reaches its ceiling all the power of the engine is used up in horizontal flight. Adequately to compare two aeroplanes in point of rate of climb, one must know the altitudes at which these climbs have been measured.

"Zooming."

Climbing must by no means be confounded with "zooming." In the former a regular speed is kept up, and, so long as the engine provides the necessary excess power, a regular rate of climb will also be possible (neglecting altitude influence). In zooming the excess of *speed* which the machine has over an above its minimum is transformed into height b means of the elevator control. If the aeroplane i racing along "all out," at, say, 100 m.p.h., it ca be zoomed up at a very steep angle indeed, until it lying Facts and Theories.—

peed falls to the supposed minimum of 60 m.p.h., fter which it must be flattened out, or else it will imply stall for lack of support. The difference etween zooming and climbing is shown graphically figs. 2 and 3 respectively. As far as a straight comparison is concerned, it will readily be seen that, if the machine starts from and attains the same respective altitudes at the same speed in each case, the zooming method ains nothing over the direct climb, though, needless say, zooming is a most valuable manœuvre for other urposes.

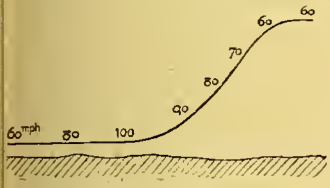

Fig. 2.

It will also be perceived that, in order to get the est climbing performance out of an aeroplane, the ir speed indicator furnishes a very useful finger post, lthough it is not strictly necessary, as a practised ilot will tell from the feel of the controls more or ss what he is doing, and he will also gain knowdge from a glance at the dial of the barometer, over hich he will seek to keep the indicating hand steadily oving. Generally speaking, however, it will pay im to retain a practically constant air speed, which, f course, will be a little higher than stalling speed.

A great many aeroplanes are provided with a trimming gear, which is brought into action for climbing purposes, and in this case the pilot will be able to adjust his "fixed" tail plane to a definite setting at which the best climb is got. He can then keep the joy-stick in a central position until it is required for manœuvring purposes. The trimming gear is, in fine, simply a device for relieving the pilot of a certain amount of fatigue, and enabling him to keep the incidence of the main planes set at an angle appropriate either to speed or climb as circumstances require.

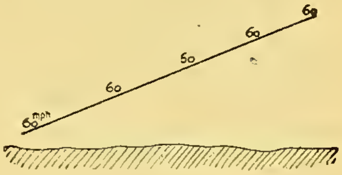

Fig. 3.

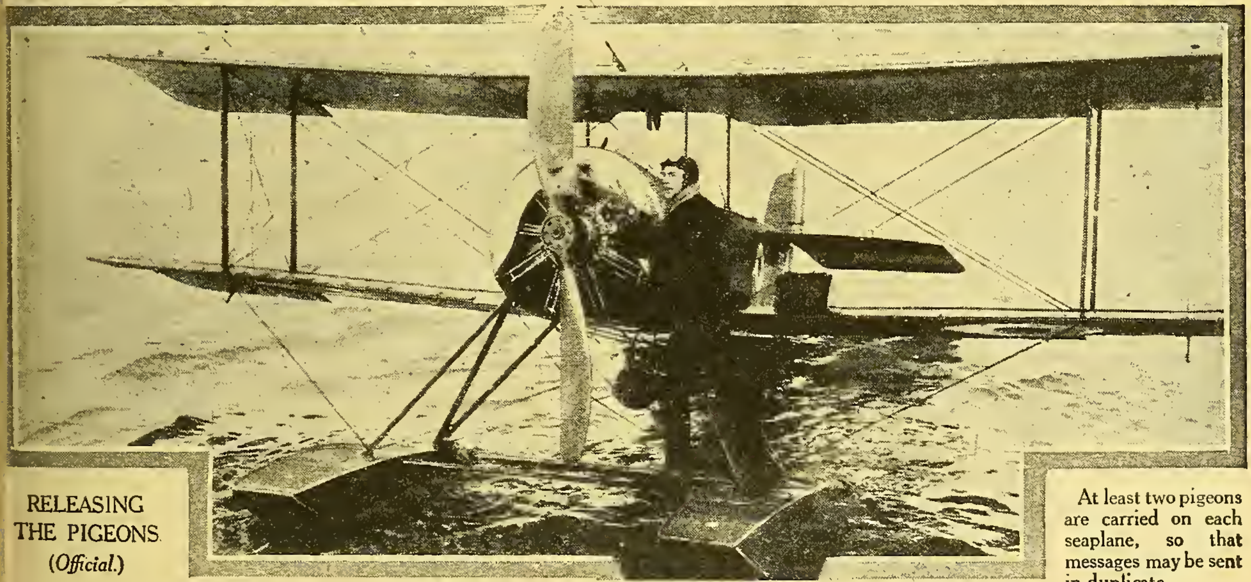
As the angle of climb becomes steeper it follows that a greater and greater proportion of the weight of the machine is borne directly by the air screw; thus if the climb were vertical the machine would cease to be an aeroplane, and become, to all intents and purposes, a helicopter. As far as I know, no make of machine yet produced has managed to climb quite perpendicularly, but there is no reason why in the comparatively near future this should not be done, even if it were not possible to make engines lighter in weight per h.p. than some examples are at the present time.

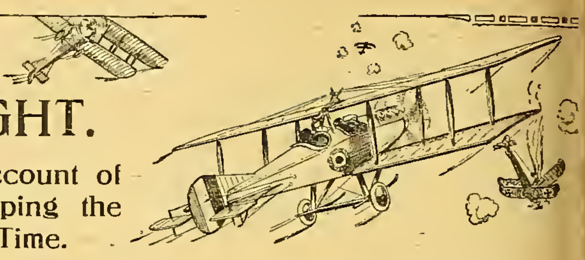


RELEASING THE PIGEONS. (*Official.*)

At least two pigeons are carried on each seaplane, so that messages may be sent in duplicate.

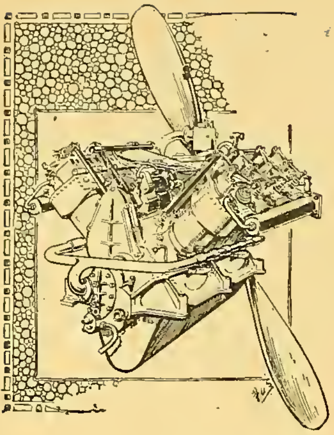
RAILWAYS, AEROPLANES, AND COLONIES.

THE main obstacle to the opening up of rich countries Overseas is the cost of railways. Colonists are impaled on a dilemma. They annot develop big markets without a railway: and a ailway cannot pay until an enormous amount of prouce and passenger traffic is assured. Even in comaratively easy districts, where labour is cheap and either rivers nor mountain ranges present serious bstacles to the track layers, a railway demands an outlay of over £20,000 per mile. Roads are about 75% less expensive, but must be capitalised at about £5,000 per mile. An aeroplane service, allowing for three trips per diem in each direction, and using machinery capable of carrying threequarters of a ton, costs about £600 per mile. It is clear that many of the "new" countries will enjoy good aeroplane services long before they can hope for extensive road or railway systems. Already plans for rapid postal service to countries difficult of access have been organised.



MY FIRST FLIGHT.

A Motor Cyclist's Account of the Sensation of Looping the Loop for the First Time.



THE roar of the big 160 h.p. engine died down into a confidential mutter, and the mechanics stood by ready to pull the chocks away from under the wheels of the towering military biplane as the pilot (one of our best known civilian testers) motioned me to my seat.

I scrambled inexpertly into the comfortable cockpit, buckled the broad safety belt about me, drew down my goggles over my motor cycling helmet, and waved to show that I was ready.

The sombre drone of our eight massive cylinders swelled again, and we moved forward bumpily, gathering speed momentarily. Across the green field we sped, and I clung to the padded arms of my seat as we rocked about. Nearer and nearer we drew to the boundary fence, until, just as it seemed we could never clear it, an abrupt cessation of vibration and a queer sense of detachment told me that we had left the ground.

With the nose of the machine well up, we soared steadily into space. An occasional lurch into an air pocket was the only interruption of the incredible smoothness of our going—not even a highly tuned twin on smoothest asphalt can compare with the velvety feel of the third dimension.

I looked down over one veering wing as we banked, and below me lay the whole countryside, arcadian and wooded, and the corrugated roofs of the hangars we had left glinted in the sunlight. Our shadow chased us, black and phantom-like, across the fields below. Far away lay the smoke-pall of London. The steady diapason of the engine throbbed in my ear drums, and we turned, as it seemed, with immense deliberation. Sense of speed there was none.

I turned to look at my pilot. He grinned through the oil splashes which covered his face (the mechanics had been very generous in the matter of lubrication with our brand new engine) and indicated by sign that we were doing ninety-eight miles an hour. Incredible!

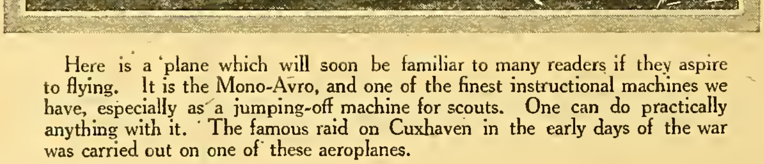
We swung about like some great gull, and then tl blurred confusion of sound hardened, and we sh upwards once more. The trees shrank to little tuf of green, and a village below us turned to tiny patch of mosaic, red and white.

I became dimly conscious that somebody wished attract my attention, and turned to see the pilot, h mouth wide open, evidently bawling at me.

He winked a goggled eye, and twirled one finge Evidently this was an invitation to loop. I nodd vehemently, and hardly had I done so when the engi shut off abruptly, so that the silence almost stunne and for the moment we seemed to poise—and th down, down, unutterably swift and steep, hurtli straight to the earth, with the wind wailing throu the wires, that lashed like the rigging of a shi Suddenly I became aware of an undue pressure on n feet, then felt the uncanny lightness that may l experienced in mountain air—hardly had time grasp the astonishing spectacle of the sun burni beneath me, and we were out of the loop, and tl slackened wires tautened again, and once more tl engine took up its monotonous refrain.

I turned round to smile appreciation. It was rath a breath-taking business, but it gave me a glimpse that queer feeling of indifference to the possible ou come that must go with the sense of high adventu possessed by those men of ours who outfly, outfigh and outmanœuvre the German at every move of th game, given only a decent machine to do it on. is not only one's body that leaves the earth: I will n attempt psycho logical analysi but there is a quee feeling of exaltatio akin to that exper enced when har after big game, an "all-out blind on a straight roa that must be felt be appreciated, an I think, must the keenest joy living.

Now we turne down, eddying lik a leaf, watching th flags round th aerodrome for wind direction; and then straightene into one long, glorious glide, coasting down the a lane silently, save for the fanning of the propelle till abruptly we straighten out—a few premonito bumps, and then the bouncing of the sturdy unde carriage as we "taxi" in. R. H. BRITTAIN.



Here is a 'plane which will soon be familiar to many readers if they aspire to flying. It is the Mono-Avro, and one of the finest instructional machines we have, especially as a jumping-off machine for scouts. One can do practically anything with it. The famous raid on Cuxhaven in the early days of the war was carried out on one of these aeroplanes.

Motorists

The "quietness" may not have pleased everybody. Reason and consideration may here and there have been mistaken for apathy. The Executive will, however, stand firmly by its programme, confident that the A.A.'s determination to assist and not to embarrass the Government during the War, has the sympathy of every reasonable motorist.

A gravely depleted staff is "carrying on." No complaint has been received from any member of inattention to a single one of the innumerable calls on the Association's resources, no matter how vital or how trivial the subject matter of such call.

The A.A. is first and last a Fighting Organisation. It was born and built up in the midst of war—war against the *unreasonable* treatment of reasonable motorists.

The A.A. has never shirked a fight. Its wonderful progress, 92,375 individual members in 8 years 11 months (August 28th, 1905, to June 30th, 1914) was achieved not merely because it fights, but because it always fights for the right thing at the right time.

The A.A. is fighting now—for the Country.

It is organised and ready to fight harder than ever for the redress of any motoring grievance on the first day when it seems *fair* to fight.

No reasonable motorist can say that that has yet arrived, or that it is fair to harass the Authorities and to distract their efforts from the more vital needs of the Nation.

To be reasonable now will ensure more power to our fighting machine when the World's War ceases and the Motorists' War is resumed.

The Peace Aims

of the A.A. include:

a. The re-application of Motorists' Millions to their original object, viz., Road maintenance and improvement.

b. Employment of Armies on Road Construction during demobilisation.

c. Continuance of all War Gas-washing Plants for Benzol, thereby adding many million gallons of Motor Spirit per annum to pre-war home production.

d. Vigorous encouragement of Home-produced Fuels and State regulation of prices to the user.

e. Complete Sign-Posting of the British Isles on National lines.

f. Drastic revision and consolidation of Motor Laws and abolition of all tolls.

When the time arrives to achieve these Aims, the A.A. will reap the fruits of its consistent patriotism, economy, care for the dependents of all its "serving" employés, prevision, and reasonableness. The A.A. will have—

1. A strong fighting programme.
2. A "Motorists' War" Fund of six figures.
3. An efficient staff of loyal workers.
4. The well-earned sympathy of all Government Departments.

It is beyond doubt that this healthy condition is attributable to a clear appreciation at the outset of the Country's grave needs, to loyalty, to watchfulness and quiet—but not any the less efficient—protection of all reasonable motorists.

By Order of the Executive Committee.

Stenson Cooke, *Secretary.*

The U.S.A. Standard Motor Cycle Engine.

Particulars of the Engine designed for the American Army Motor Cycle.

WE have already announced that the American Army is to be supplied with a standard motor cycle for use ir he war zone, and we are now able to gi some particulars of the engine of th machine, although at present details of he machine itself are not available.

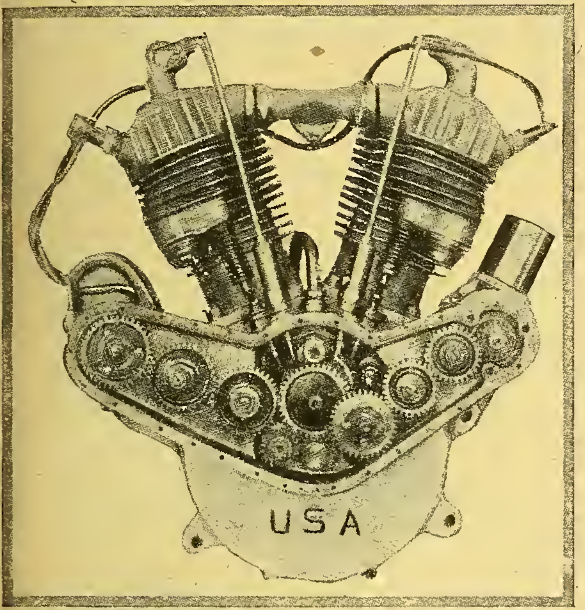

Fig. 1.—The U.S.A. standard motor cycle engine with gear cover removed. The bore and stroke are 84·5 × 89 mm. = 996·5 c.c.

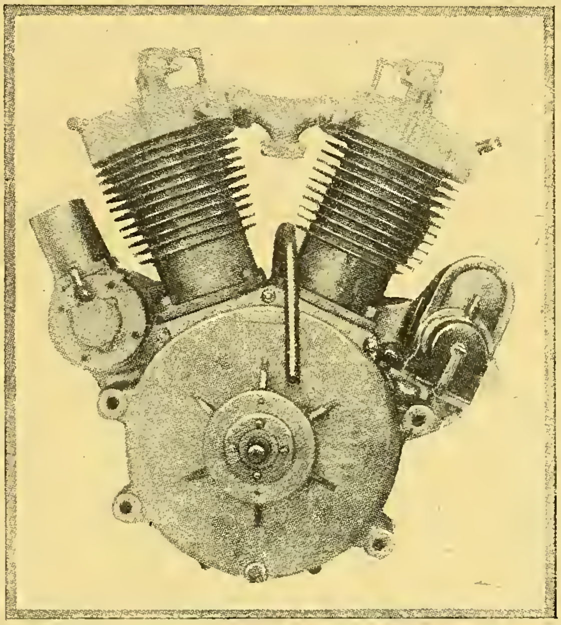

Fig. 2.—The driving side of the U.S.A. standard engine, showing generator and magneto mountings, the brackets of which are cast integral with the crank case.

A 90% of the motor cycles are to be us fitted with sidecars, the compression ra of the engine is much lower than th usually employed, and is, in fact, 3 to 1.

Crank Case Details.

he engine is of the twin-cylinder V ty, the angle of the cylinders being 45 and the bore and stroke $3\frac{5}{16}$in. × $3\frac{1}{2}$in. =.5×89 mm., giving a capacity of 6 4 cu. in.=996.5 c.c. Looking at the il trations of the engine, the m striking feature is the provi n for the magneto and the li ting dynamo. The brackets for the two fittings are cast integral w the crank case, so that both the fittings are an essential fe ure of the engine design. A ther departure from usual A erican practice is made in that th crank case forms a part of the cy e frame, as in normal English p tice. The valves are overhead in ts, placed in cages above the ex usts, and all valve springs are er osed.

Lubrication.

ubrication is, of course, of the m hanically-operated oil pump ty e. The plunger pump is positi ly driven, and the valve in the p p is a rotary; thus the troubles often occurring with the ball and check valve type of pump are avoided. A supplementary hand pump is, of course, fitted. The crank case release valve strikes a somewhat unusual departure, in that it is a rotary valve mechanically operated, and consequently does not rely on crank case compression or suction for its working. This valve is so timed that there is always a slight amount of suction in the crank case, and it is claimed that this will tend to ensure that the exterior of the crank case will be free from superfluous oil.

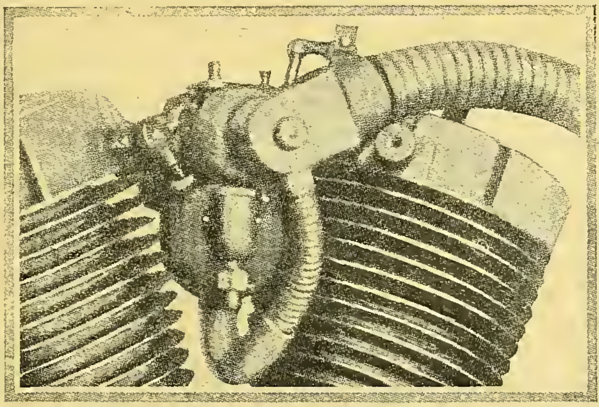

Fig. 3.—A carburetter that may be adopted for the U.S.A. motor cycle engine.

Carburation.

The carburetter is not yet definitely decided upon, but it is understood that one at present in common use on most motor cycles will be fitted, and will be supplemented by the fitting of an air strainer to the carburetter itself.

Power Output.

The power output of the engine is 15.3 h.p. at 2,900 r.p.m., which, of course, is nothing exceptional, as the engine is deliberately designed not to give excessive power but to be able to maintain its output under gruelling and difficult conditions. Further experiments are being carried out, and it is anticipated that some minor alterations to the engine may be made, but these will not be made with the intention of actually increasing the power output, for in a machine that is to be used under rough conditions the highest efficiency is not necessarily an essential.

The Lighting Dynamo.

The lighting arrangements contain the germs of novelty, in that the dynamo itself runs at twice engine speed, and, although it is driven directly from the timing gear by worm gearing, it may be disconnected during the day time so that excessive wear may be avoided.

This disconnecting arrangement is ingeniously constructed so as to prevent the engagement of the dynamo, either deliberately or by accident, while the engine is running; consequently the risk of a careless driver's ruining the dynamo and its drive by suddenly engaging the dog clutches while riding the machine or while the engine is running, with the object of saving a little time, is prevented.

Letters to the Editor

The Editor does not hold himself responsible for the opinions of his correspondents.

THE CASE FOR THE LONG STROKE.

Sir,—Replying to the article of Mr. Alex. Lindsay, M.B., the "Case for the Long Stroke," in your issue of the 28th March, as to the bore and stroke of the 500 c.c. racing M.A.G., I am pleased to give the information for which he asks, which is 64×77 mm., and of the 7-9 h.p. or 1,000 c.c. engine 82×94 mm.

OSBORNE DE LISSA, Director,
THE M.A.G. ENGINE CO., LTD.

ARMY SIDECAR DRIVERS.

Sir,—If Mr. P. Thurston is so keen to drive a motor car let him join the Heavy Branch, and drive a Tank. We are awfully sorry that he cannot get into the A.S.C., M.T., "notwithstanding that his father has served two years with this corps." We are sure that he is not looking for a "cushy" job. He must have overlooked the Tank Corps. There is plenty of scope for his experience there.

G. A. KING.
Tank Corps, B.E.F. H. DOMINY.

A RALEIGH FOUR-SPEED FLAT TWIN?

Sir,—With reference to the prediction in your issue of April 11th that the Raleigh will market a post-war motor bicycle with flat twin engine and four-speed gear, we should like to point out that we have no intention of doing this. It is true that we have patented a four-speed gear box, but any motor bicycle we put on the market will incorporate the Sturmey-Archer *three-speed* countershaft gear, which has been so well proven on despatch riders' machines during the war.

We shall be glad if you will therefore correct the wrong impression which has been created regarding the gear box.

THE RALEIGH CYCLE CO., LTD.,
Harold Bowden, Managing Director.

SIDECAR ALIGNMENT.

Sir,—Articles have appeared in *The Motor Cycle* from time to time on the design, mechanism, alignment, etc., of the sidecar chassis, alone and in combination. In all of them a most important factor has been consistently ignored, viz., the fact that more often than not the vehicle is moving not upon a level surface, but on one which slopes down from right to left. Deplorable results of this ignoring of the camber of roads are frequently seen. Many of your readers will agree with me that nineteen out of twenty combinations have many of the following characteristics: (1.) The sidecar wheel inclines inwards. (2.) The bicycle leans towards the sidecar. (3.) The body of the sidecar is nearer to the left C spring than to the right. (4.) All three tyres are worn more on the inside than on the outside, the front tyre especially so. (5.) The saddle is more easily depressed on the left than on the right-hand side, with consequent discomfort in riding. (6.) The chassis is bent laterally, being lower at the middle than at the sides. (7.) The springs on the left of the body have acquired a permanent "set," with the result that the body is tilted even in relation to its own chassis.

In driving such a machine excessive side-drag is felt, especially when turning a right-hand corner while driving on the left side of the road.

One combination I remember—a new 6 h.p. machine—was only three weeks on the road when the coachwork of the near side of the body was ruined by being thrown against the upper part of the C spring. On another machine I once overtook on the road, the coach body was in contact with the mudguard. Both these combinations were complete integral outfits by well-known makers. And how many outfits one meets in which the driver apparently has his left leg trapped between the tank and the sidecar?

A sidecar I once possessed had its left C spring deformed to such an extent that I had to place wooden blocks 1½in deep between the spring and the chassis.

These defects may be removed, or at least minimised, very simply by either fitting a 28in. wheel to the sidecar or coupling the axle tube of the chassis to the cycle by means of an adjustable coupling. Those riders who have a Montgomery, A.J.S., or Phœnix sidecar (there may be others) will be able to make a suitable adjustment merely by the use of a spanner. The axle tube should be dropped one inch below the hub of the driving wheel. A convenient way of doing this is to put the cycle on a one-inch plank, and then attach the sidecar in the usual way.

I have even found it necessary to have the cycle sloping a little away from the sidecar at first, say, a quarter of an inch out of parallel at the top of the tank. The stresses set up in the couplings in turning a right-hand corner on the left camber of the road are so great that in the course of a run of a hundred miles it will probably be found that the quarter of an inch divergence has disappeared, and that the sidecar wheel is truly parallel with the cycle wheels.

The only drawback of this arrangement is that a little more care must be exercised in driving on the right-hand side of the road. Also it could not be used in the case of a featherweight sidecar

Most roads nowadays have a double row of pot-holes in the wheel tracks. A combination in which the sidecar wheel is one inch below the cycle wheels may be driven on the smooth ground on each side of the left-hand wheel track and still be nearly vertical, in spite of the camber of the road.

Finally, no chassis and no couplings ever made will withstand the additional centrifugal force of a right-hand turn with a pillion passenger. A. L. GRAY.

THE HORIZONTAL COUPLE.

Sir,—After reading "Wharfedale's" article in *The Motor Cycle* of April 11th, I find myself a little at a loss to know what is the origin of the couple in the flat twin. I had always understood that it was due to the inertia of the reciprocating parts, and your contributor himself seems to lean towards this view in the latter part of the article. In the first part, however, he gives me the impression that it is connected in some manner with the explosion pressure on the pistons. If "Wharfedale" holds the latter view I am somewhat surprised; but I cannot think otherwise when he writes of "the forces applied from the cylinders" and states that the couple is anti-clockwise. If he held the usual theory he would surely realise that the couple is constantly changing in magnitude, and reverses its direction each time the pistons pass the point of maximum velocity. Moreover, he shows a diagram to prove that there is no couple in the vertical twin. This, of course, is perfectly correct if the cranks are together; but the accepted form has the cranks at 180°, in which case there is a very bad couple indeed. The Scott is a case in point. I shall be interested to know whether "Wharfedale" has discovered a new theory of balancing, or whether he is merely a trifle hazy in his notions on the subject. BOB-WEIGHT.

Kenilworth.

A PLEA FOR HIGHER GEARS.

Sir,—I notice that a correspondent in *The Motor Cycle* of March 28th puts forward a plea for lower gears. May I put forward a plea for *higher* gears?

In my opinion, a low-geared motor cycle is an abomination I exclude "flat" twins, as I have had no extensive experience of these). When on the open road I think there is nothing more exhilarating than to spin along with the engine just turning over comfortably. I have had experience of ightweights, singles, V twins, and a four, and find that a high gear is far pleasanter in every case. My last 'bus, a 7-9 h.p. twin, was geared $3\frac{1}{4}$ to 1, and on the road it was 'priceless.'' I have yet to find a two-stroke that could fire as evenly as that bicycle did.

After the war I sincerely hope that some first-class British manufacturer will produce an 8-10 h.p. four-cylinder motor cycle that will be suitable for solo use. If it were geared about 3 to 1 on top I can imagine nothing better.

Wood Green. FOUR CRAZY.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—We, the motor cyclists of the 190 and 192 N.T. Squadrons, heartily endorse the remarks made by "Old Reader" and "Air Mechanics" in your valuable and echnical journal on April 4th.

The matter of pay and promotion, although of some mportance, is outdone by the degradation of being called 'non-technical privates," and not being allowed to keep he honourable title of (air) mechanics, in spite of the fact hat we do all our own repairs and adjustments, and that ach one of us thoroughly understands every part of his machine, and has to pass a theoretical and practical trade est in technical matters relating to internal combustion ngines before being admitted to the ranks of motor cyclists.

In nearly every case here, the motor cyclists own machines n private life, and have gained all their technical knowledge rom their motor cycles.

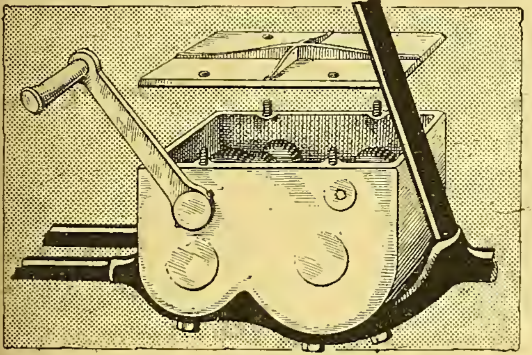
We are sure that you will support us on this point—that t is a grave insult to the whole of the motor cycling raternity that we should be classed non-technical, while ur more fortunate pals the M.T. drivers are classed technial and have all their repairs and overhauls done for them.

I may say that this is the opinion of most motor cyclists erving with the R.A.F., and you would do us a great ervice if you would forward our grievance, through the nfluence of your esteemed journal, to the right quarter.

A FEW NON-TECHNICAL PRIVATES, R.A.F.

MOTOR CYCLE DESIGN.

Sir,—I note your correspondent, "An Australian," remarks n the method of supporting gear boxes. The only proper way is to support the gear box below and leave the top of he box free for removal. By taking off four nuts the cover ould then be taken off at once and the actual process of hanging gear and action of the kick-starter could be seen, lso state of wear of the parts and lubrication. A felt or eather washer under the cover would make the box abso-utely oil and dust-tight, which is not the case when the ront or end of the box is made removable. The present rthodox fashion of hermetically sealing up the "works" n a case is absurd, and it often requires an expert to take he gear to pieces and reassemble.



A suggested method of supporting a gear box.

The box also should be made of a single casting of malleable iron or steel, which is far stronger and cheaper than aluminium, and the slight extra weight is of no practical account whatever.

When will some firm turn out a really practical gear box on the above lines? Sturmey-Archer "works" in such a box would be ideal.

With regard to my remarks on removable back wheel spindles, a loose spindle and gap piece for removal of endless tube would satisfy most riders. The detachable spare wheel is a luxury which all cannot afford (£5 or £6), besides which it is only fitted to a few makes of machines.

M. HITCHCOCK.

A POST-WAR IDEAL.

Sir,—May I ask the favour of a few lines to reply to "Gee Whizz Bang" and Mr. W. R. Deuchar?

"G.W.B." does not seem to like the Radco spring forks, but I wonder if he has ever used a pair for any distance over war time roads. They are absolutely "It."

I must say that I have not seen any new Druids, but it would take a lot to alter my opinion of Radco forks.

I am pleased also "G.W.B." likes my ideas, as I thought they would be hurriedly criticised. A motor cycle on those lines would certainly look and be "hot stuff," as he remarks.

Mr. W. R. Deuchar certainly seems to have backed the winner in his letter regarding "A Tilter at Windmills," and he seems to think that a large single two-stroke on the lines I suggest, with slightly polished copper exhaust pipe, 3ft. long and 2in. bore, and disc wheels, would certainly be a machine on sporting lines.

By the way, "Ixion" seems to have got something "up his sleeve" by what he says in his "Comments" in the April 4th issue. I wonder what it is. G. A. JEAPES.

AVERAGE SPEED.

Sir,—I must apologise for carrying on the much vexed question *re* average speed, but in your issue of January 17th (which has just reached me) "H.C.W." has made one or two mistakes which I think might be rectified. To commence with, he is confusing a certain "Eldon," who, I think, rode a 7 h.p. Indian, with myself, and my 8 h.p. Bat. If I remember rightly, "Eldon" did nine miles in 11m., and my time for nine miles was 10m.

As "H.C.W." knows the Cheltenham-Tewkesbury road so well, I may tell him I started from North Street, Cheltenham, and reached The Cross at Tewkesbury in exactly ten minutes, reaching Worcester (fifteen miles from Tewkesbury and twenty-four from Cheltenham) in twenty-nine minutes. I maintain that with a very fast machine over favourable roads, even when allowing for dangerous corners, it is possible to average a very high speed indeed with perfect safety.

My Bat machine was capable of a maximum speed of close on 80 m.p.h., which speed, of course, was only maintained for a few seconds at a time, but that extra 20 m.p.h. on the maximum of most motor cycles makes all the difference in average speed. Again, a machine so obviously over-powered as mine literally never noticed the hills. For instance, I could go up Harley Bank at something between 50 and 60 m.p.h. till the top corner was reached, where, of course, one would shut down as for the same corner on the level.

I should like to add that, in spite of the very high average speed I used to maintain over give and take roads in all the time I owned the motor bicycle (just over two years), I never had the slightest mishap of any sort. The machine was geared $3\frac{5}{8}$ to 1 fixed gear, and overhead valves.

If a rider knows his mount in and out he can maintain a much higher average, with absolutely no risk to himself or anyone else, than another rider, even if on the same machine, who does not know his mount's peculiarities, chief of which are maximum speed up hill and on the level, acceleration, and braking powers.

I hope I shall be forgiven for trespassing on your valuable space at such length, but I fail to see why a rider who is capable of riding a fast machine with perfect safety to others and himself should not be allowed to do so

In conclusion, may I wish your excellent paper the best of prosperity and success? With luck, we usually manage to get it every week.

May I add that I have no interest in the Bat except as a thoroughly satisfied owner? AD 2815.

E.E.F.

THE BICYCLIST'S EQUILIBRIUM.

Sir,—The articles by Mr. W. Arthur Jones and "Mohandis" in your issues of January 31st and March 14th respectively have provided such interesting reading that I trust I shall be permitted to add a few comments on the points which have been raised.

As Mr. Jones has stated, it is necessary to get down to simple first principles, and he has clearly shown that a deviation from the straight line calls into play a force which he describes as F, tending to right the machine, and he proceeds to discuss the nature of this force. I find myself in complete agreement with him thus far, also with his conclusion that this force is none other than gravity.

In a letter which appeared in your issue of July 14th, 1910, I endeavoured to show how this force was set up, and as many of your readers may not have seen the issue referred to you will perhaps pardon me if I repeat the paragraphs bearing on the subject.

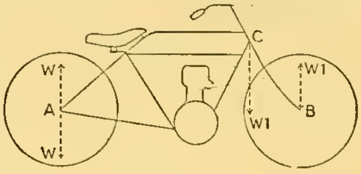


Fig. 1.

"In fig. 1, which represents a bicycle standing upright, we see that the weight of the frame and rider acts vertically downwards at A and C, whilst the supporting reaction of the road acts upwards through A and B. When a rider on a straight course feels he is falling to one side he instinctively turns his front wheel to that side, so that C falls outside the vertical plane through A and B, and the couple W at C and B immediately rights the machine.

"Now when a rider turns his front wheel to get round a corner, besides leaning inwards to balance the centrifugal force he has to overcome this couple in order to balance the machine. When a sharp corner has to be taken quickly the rider has to turn his wheel through a considerable angle, which increases C D (fig. 2) and gives him a greater couple to overcome, viz., W × C D. Hence, by keeping his body still (or inclining it outwards) and inclining the machine inwards still more than it would be if he inclined himself as well, he brings C nearer the plane of A and B, and is enabled to get a greater angle on his front wheel and take a sharper turn in the road."

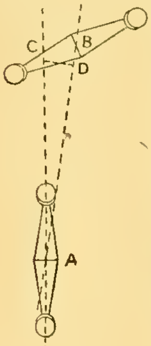

Fig. 2.

"Mohandis" has been at considerable pains in his article to show that the rider's centre of gravity has travelled in a curved path in "righting" a "wobble," and hence centrifugal force has come into play. This is undoubtedly correct, but I am entirely out of sympathy with him when he says, "It is only a question of terminology whether centrifugal force or 'shifting the point of support' plays the greater part in balancing." The second paragraph of my letter quoted above supports the contention of Mr. Jones when he states that centrifugal force simply tends to increase the banking slightly.

I am of opinion that gyroscopic action, which is made so much of by "Mohandis," has very little influence on the balancing of a bicycle, for it is possible to imagine a machine with wheels so light that their gyroscopic action becomes negligible.

R. VINCENT BORNER.

A BAFFLING EXPERIENCE.

Sir,—About midnight recently I had a baffling experience with my countershaft Triumph. Misfiring started, and after a few yards the engine stopped firing altogether. Suspecting shortage of petrol, I looked to this, and found plenty in the tank. By the aid of an extra friendly light I dismantled the carburetter, and found the jet clear, the pipe from the tank free, and a good flow from the tank itself. Evidently ignition, I thought, and held the plug body whilst turning the engine over by kick starter. No shock from the Lodge three-point plug, which had been working perfectly for thousands of miles up to this moment. I tried another Lodge, a single-point racing plug, with the same result. I laid the plugs on the cylinder and got a spark from each in turn, replaced the original—no shock with plug *in situ.* Tried the single-point again; still no result. Held termin and got healthy shock, replaced terminal on plug, and trie again. Nothing doing! By this time I was rather fed u so invoked assistance from a mechanic at an adjacent 'bu garage, who, with my help, went over the ground agai with similar fruitless results.

My last train home being perilously near, I decided t leave further investigation until next day, and left th machine with the friendly mechanic. Next morning whe I called he invited me to try to start as usual. Taking n risk with the Government petrol, I injected, tickled an kicked, with the result that it roared out at first kick The original three-point plug was used. I asked him wha he had done, and he said, nothing but clean the plug an close up one of the points a little. The plug was not reall dirty, and the points were as they have been for month past. I tried the single-point plug, which had been in m pocket amongst tobacco dust, etc., all night, with sam result—fired first kick.

I have tried to fathom the mystery, but own myself beaten I have read in the past about plugs that would spark out side, but would not spark under compression, but could no find any reference in "Hints and Tips" and "Motor Cycle and How to Manage Them," which have an honoured plac on my shelf. The magneto and high-tension wire were presumably, right, or we should not have got a spark fro each plug when outside. The fault could not have been wit the plug, as the single-point worked the next day, althoug not touched or cleaned in the interim. On the contrary it had been in the pocket of a damp overall all night.

As it happened I was not terribly inconvenienced, havin a garage near to which to take the bicycle and a station 25 yards away where I could get a train. But picture me mile from anywhere at the same hour, viz., midnight, with s baffling a problem.

Perhaps it can be easily explained. If not, and you thin the subject of sufficient interest, I shall be glad if yo can find room in *The Motor Cycle* for my letter. Some o your readers may have had a similar experience, or possibl Messrs. Lodge or the Triumph Co. may be able to thro light on the subject.

F. W. CHAPMAN.

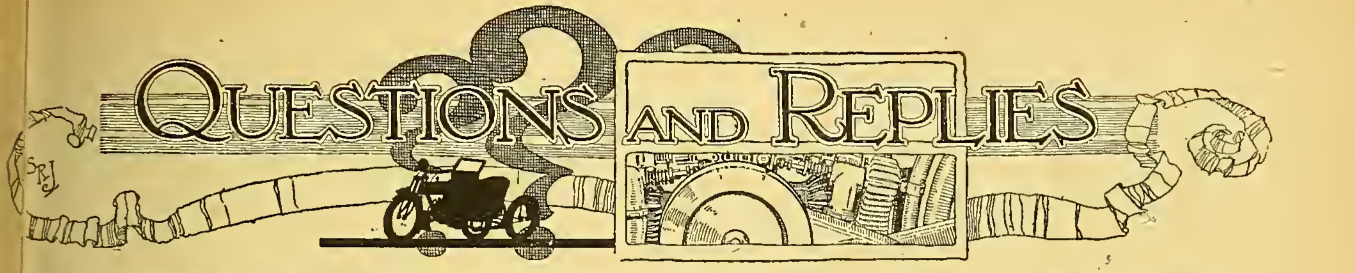
AERO AND MOTOR CYCLE ENGINES.

Sir,—Some little time ago "Road Rider" stated that 200 c.c. flat twin engine built on aero engine principle would equal in road performances the standard of a 4 h.p single-cylinder. Now steel cylinders, aluminium allo cylinder heads, and aluminium alloy pistons will not trans form a 2 h.p. engine into a 4 h.p. engine. Such an engin as "Road Rider" describes would probably have to b geared in the neighbourhood of 10 to 1 on top to giv the power output of the modern 4 h.p. single, and, sinc he states that the upper third of the revolution curve has been surrendered in the interests of dogged pulling on hills the engine would therefore be very slow compared to th present 4 h.p. single. The revolutions would be tremendously high from the start of a run to the finish, and I question whether the aluminium cylinders and pistons would prevent overheating and consequent carbonisation. "Road Rider" proposes fins of paper thickness. Now this thinness of the radiating fins can be carried too far, a paper thickness fins would pass very little heat from th cylinder. Radiating fins should be fairly thick where they join the cylinder and thin at the edges. They must hav sufficient body of metal in them to carry away the flow of heat from the cylinder walls. The same argument applies to the thin piston head supported by a bracket bearing on the gudgeon pin proposed by "Road Rider." In an aluminium piston the piston top can be made twice as thick as cast iron with advantage, in that the continuous flow of heat on the top of the piston is rapidly conducted to th cylinder wall. With a bracket supporting the top of th piston a large proportion of the heat would be conveyed to the little end bearing, which is undesirable.

Apart from all these things, his engine would make an awful fuss and clatter with its four overhead valves pe cylinder, and would take up a great deal of time keeping tappets and rocker arms adjusted. Aluminium cylinders and pistons will become universal, in my opinion, but obviously the engine must have sufficient cubic capacity to enable it to do its work easily and to maintain its tune.

Worcester. 670 C.C.

QUESTIONS AND REPLIES



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," , Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents e urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal iestions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Carrying a Passenger.

Could you please tell mé if I am allowed to take anyone in my sidecar when I am on business? I am a commercial traveller, and use a motor cycle and sidecar my rounds.—W.C.

If ou have a permit or other permission to use your machine, the carriage of a passenger does not in any way affect the permit.

The Motor Spirit Restriction Order.

(1.) Could permission be got to drive a motor cycle from Swansea to Gloucester on the grounds of change of residence? (2.) To whom should the application be dressed? (3.) Would the Inland evenue licence have to be paid? (4.) have sufficient petrol saved from last ason, and my driving licence does not pire until May 24th. Would it be ise to apply for sufficient petrol for ie journey under the circumstances of ie last question?—R.H.H.

(nd 2.) A special permit is not usually n essary, but it might be as well to put tl circumstances of the case before the P rol Controller, 19, Berkeley Street, L don, W.1. (3.) Yes; the local t ation licence has to be paid. (4.) W en permit is granted you may use the p rol in question. Whether you will n d more petrol is for yourself to say, as it epends on how much you have in stock.

Joining the A.S.C.

I should be glad if you or any of your readers could supply me with any information regarding the O.T.C. of the A.S.C., M.T. —B.H.H.

u should obtain an A.F. M.T.393A f n any military depot, or if no local d ot can supply you with this form you s uld be able to obtain one from the C . Troops. This form must be filled i and returned to the O.C. of the A.S.C., M.T., O.T.C. The statement will have t be supported by a present A.S.C. o cer who can vouch for your qualifica- t ns from personal experience. The t ining depends entirely on the branch o the A.S.C., M.T., for which you intend t enter, and can only be satisfactorily a swered by the O.C. or adjutant of the O.T.C. himself. Particulars as to pay, u iform, etc., may be obtained from the S cretary of the War Office, Whitehall, I ndon, S.W.1. If you are already in t Services all steps must be taken t rough your present O.C. in the ordi- ry way.

The Paper Shortage

An Urgent Request to our Readers.

THE supply of paper is now so restricted that only by exercising the greatest economy and eliminating the possibilities of waste can the publishers of "The Motor Cycle" continue to meet the requirements of the public.

The position is serious, and is likely to grow worse as month by month the war makes greater demands upon the available shipping space.

Once again and with greater urgency an appeal is made to readers to lend their assistance to the publishers in effecting the necessary economy by placing definite orders with their newsagents for copies to be reserved or delivered each week.

This will enable the newsagents to limit their orders to the numbers they can actually sell, and thus avoid the wastage that may be caused by copies ordered to meet chance sales being left unsold.

If each reader will order and regularly obtain his copies from the same newsagent the publishers will be in a better position to gauge the requirements week by week, and, by strictly limiting their printing orders, keep the consumption of paper within the limits demanded by the present situation, while at the same time ensuring sufficient copies being available for all regular readers.

In view of the gravity of the position, those readers who have not yet given orders to their newsagents are urgently requested to take this very necessary step immediately.

Starting Motor Cycling.

I am thinking of going in for a lightweight motor cycle. Can you advise me as to what type would suit me, as it will be my first mount? Should I find any difficulty in obtaining a licence for petrol or driving?—H.H.L.

Your query is far too general to admit of a definite answer; so much depends on your age and requirements. You will find very great difficulty in obtaining a licence for petrol at the present time, but no difficulty in procuring a driving licence.

Boiling Alcohol as Fuel.

A few years ago, probably about three, I remember reading in *The Motor Cycle* an account of an American engine which derived its power from boiling petrol. If my memory serves me rightly, the engine was a form of rotary and circular in design. There were one or two illustrations given, and it was stated that the engine was of a type commonly used in the United States for motor boat work up to just a few years before the appearance of the article. Perhaps you can help me in tracing this article so that I can have another look at it.—D.W.

We think you must be referring to an engine which runs on boiling alcohol. This is described in *The Light Car* for November 14th last. The Low engine used boiling petrol, but this was an English production.

Reassembling a Hub Gear.

I have just had my Sturmey-Archer hub to pieces, and when I came to put it back again I had to throw the clutch out before I could force the plates in again, of which there seemed to be about twice too many. Now they are back the free engine clutch will not act at all, and the wheel is terribly hard to pull round. Can you tell me of any remedy for this, as I have tried everything of which I can think?—S.L.

There are so many possible faults in reassembling the three-speed hub gear that it is impossible to diagnose exactly the cause of your trouble without the chance of seeing the hub. We assume that you have ascertained that the clutch operating rod is working properly, and that the adjustment of this rod will not cure the trouble. If, as you say, you found the plates would not go back in the original space, we suggest that you take the gear to a competent repairer.

Removing the Valve Guide.

The valve guide of my 3½ h.p. Zenith (J.A.P. engine) is slightly broken inside and outside. Is it possible for an amateur to remove the old one and insert a new one? If so, would you please tell me the best method?—G.A.H.

The best plan will be to heat the cylinder round the valve guide with a blow pipe, and this, you will find, will loosen the guide sufficiently, so that you will be able to remove it by means of a spanner.

Truing Up Flywheels.

I have taken the flywheels out of the crank case of my 2¾ h.p. New Hudson motor cycle to have the little end rebushed, and would be obliged if you would help me out of the following difficulty. How can I know whether the two flywheels are true after I have put the connecting rod on and fastened the nut on the crank pin? I have no lathe—W.W.R.

It is rather a difficult job to get the flywheels quite true without a lathe or suitable jig. We suggest you get the crank pin nut fairly tight, and then place a straight edge across the flywheels at different points round their edges. This will enable you to see at a glance whether or not the flywheels are true. By judiciously tapping them you can soon get them perfectly even, and you then tighten the crank pin nut as tightly as you can get it.

All about Two-strokes.

Would you be kind enough to answer the following queries concerning a Junior Triumph two-stroke? (1.) I wish to find out if the petrol level and jet are correct without having to tinker about with the carburetter. Is there any means of judging this by, say, the amount of air it takes? I cannot judge by mileage, as I only do about ten miles per week. The machine is running well, but I wish to economise as much as possible compatible with good running. (2.) I believe that to lower the level I should have to lower the float by tapping down the collar above it (as it is an overhead feed). I should be glad if you would give me full directions how to do this, and what distance it should be lowered. What effect would only half opening the petrol tap have? (3.) What distance apart should the plug points be? (4.) The carburetter on the machine is the original one put on by the makers. At present I have float with hollow part underneath. Is this correct? (5.) How can I tell if the needle is worn? (6.) In going a long run, is it necessary to give extra oil at all, and how? (7.) Could you tell me the principle of petroil lubrication? Does the oil get separated from the petroil in the carburetter? (8.) Will you please tell me if it is necessary to grind in the exhaust release valve at all?—A.C.S.

(1.) You may be pretty certain that the level is correct unless anybody has been interfering with the carbureter. The only means of finding out is to remove the top of the vaporising chamber of the carburetter so that you can see the jet. Take the jet out and in its place fit a wide tube of the same height as the jet when pushed into position. This would be a sort of dummy jet fitted in place of the standard jet. You then turn on the petrol and allow the float chamber to fill, when the level should be just below the top. You will know that you have the correct jet in your engine by the fact that you can only open the air fully when travelling at full speed. (2.) As we mentioned before, it is most unlikely that the petrol level is incorrect. If it is you will know this by the fact that if the level is too high petrol will be always overflowing from the jet, and the consumption will be very high, while if it is not high enough the carburetter will be starved, the engine will be difficult to start, and there will be loss of power and irregular running. The collar referred to is a tight fit and soldered as well, and to remove it it will have to be held in a gas flame, then the collar gently tapped. To reduce the level collar is lowered on the needle. One thirty-second of an inch will make an appreciable difference. The effect of only opening the petrol tap half-way might be that the carburetter would be starved of petrol. (3.) Rather over half a millimetre. (4.) This arrangement is quite correct. (5.) By the carburetter flooding violently. (6.) No; this should not be necessary. (7.) The oil and petrol mixed flow through the jet, and as they enter the crank case the petrol becomes vaporised, leaving globules of oil to lubricate the cylinder and bearings. (8.) Not unless it leaks and you lose compression through it.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

The Low-tension Magneto.

Will you please inform me if I can run a low-tension magneto either way? The timing on the engine (cycle) works anti-clockwise and the low-tension magneto clockwise. I want to work with a chain. Can I get a book on low-tension magnetos?—C.L.D.

If the contact breaker is not driven from the magneto in any way there is no reason why the magneto should not revolve either clockwise or anti-clockwise. The direction of revolution is determined entirely by the setting of the contact breaker. We assume that your magneto is of the rotating and not of the oscillating type. If of the latter, there is, of course, no question of clockwise or anti-clockwise. As the low-tension magneto is now obsolete except on stationary engines, we regret that we cannot tell you of any book dealing with it. It would be dealt with, however, in any old book on ignition systems for motor ca but such a book would most probably out of print, and consequently diffic to obtain.

The Local Taxation Licence.

Would you kindly inform if it is compulsory for me to the local taxation licence f motor cycle, as I have not tal it out owing to the petrol restı tions? The authorities have threater me for not so doing. Are there means of avoiding payment of the d under the present circumstances?—A

You are not compelled to pay the local taxation licence in respect of machine which is kept *but not us* The authorities, therefore, can take steps against you if you do not use motor cycle.

Loss of Power on a Two-stroke.

In May, 1916, I purchased 2½ h.p. Ixion two-stroke mo cycle. I rode it six months, w an average mileage of 120 week. I then joined the Ar and put it by for twelve months I returned again. It was kept ir thoroughly dry place, and was looked after. About a month afte began to use it again it lost consid able power, and would not climb e a moderate hill on high gear (it is two-speed machine). I purchased a fitted a new piston complete, but t has made no difference. I shall glad if you will let me know what think is the cause of loss of power a how it could be remedied.—R.B.

If you are quite certain that the pis rings are not gummed up and are a g fit in the cylinder, we should advise to make a careful search for air lea both in the induction system and in crank case, *e.g.*, round the washer at join between the two halves of the cra case. Also, it would be a good thing ascertain that all the ports (inlet, exhau and transfer) are quite clear and f from obstruction.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

The Non-technical Motor Cyclist.

WHILE looking through the regulations of the newly constituted Royal Air Force, we were astonished to see that motor cyclists are counted as non-technical men, while ordinary M.T. drivers are reckoned as technical men, and consequently get an increased rate of pay. It is not surprising, therefore, to find in *The Motor Cycle* letters of protest against this state of affairs from R.A.F. motor cyclists.

We are quite in agreement with our correspondents' contentions, as it is evident that whoever was responsible for this classification neither understood nor realised the conditions under which an army motor cyclist works. It is true that mechanically the lorry driver has more to look after and a more complicated piece of machinery to understand, but it is certainly more trouble to keep an air-cooled single-cylinder engine in tune and repair, owing to the more frequent necessity for decarbonising the cylinder and piston, than it is a water-cooled four-cylinder motor, which will run for far longer periods without attention; moreover, when the latter needs repair it is given over to a fitter for the purpose, while the motor cyclist must tune and adjust his own mount.

"The least the authorities could do," writes one of our correspondents, "would be to classify us as D.R.'s instead of privates, considering the rough job we have." This seems to be a very happy suggestion, as the R.A.F. motor cyclists certainly deserve recognition, and might well be graded as they desire. "Also," he writes, "why should we not have some distinctive badge to wear, as other motor cyclists in other corps?" Here our reader is in error, as there is no official badge designating a motor cyclist D.R.

So much splendid work has been done by motor cyclists in this war, work which is recognised by officers of the highest rank, that we are sure that if this matter is brought before the authorities it will receive attention. We therefore respectfully urge that the R.A.F. motor cyclists receive the recognition which is clearly their just due.

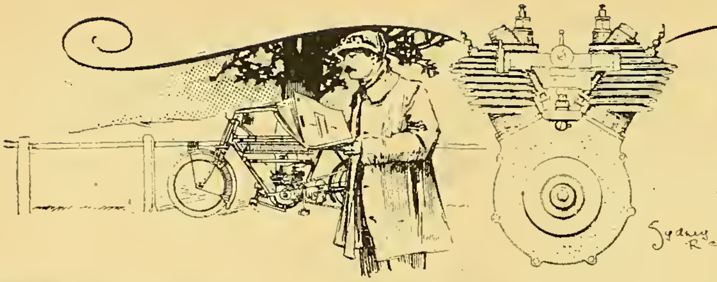
The Choice of Gear Ratios.

A FEW weeks ago—to be precise, on March 28th—we printed, in our Correspondence columns, a letter entitled "A Plea for Lower Gears," and last week another correspondent made out a case for the other extreme. Each writer had good reasons for his point of view. The question is to a large extent a personal one. The top speed enthusiast, who likes to do the major part of his running without changing down, and loves to boast of having climbed Alms Hill "on top," *must* gear low—rather too low, in fact, for the best all-round results. Then, again, an engine which attains its power by means of its "revving" capacity—*e.g.*, many of the flat twins—is well suited to a low gear, and, further, a low gear is imperative when the engine is small and low-powered in relation to the weight, which it often is in the case of a lightweight or of a sidecar outfit.

One rider may love the buzz of a two-stroke or small twin, which is *anathema* to another whose ideal it is to "pobble" along with a powerful engine turning over slowly or to indulge in a burst of high speed at moderate engine r.p.m.

It seems to us that a high gear demands a powerful engine, which, while doing its work at a reasonable speed, is still working well within the limits of its power. Few things are more distressing to the lover of machinery than to hear an engine konking its heart out while climbing a hill on a high gear when a movement of the gear lever would result in not only an easier but a quicker climb. As Aristotle says, the mean state is the most desirable.

An index to the advertisements in this issue will be found on the page facing the back cover



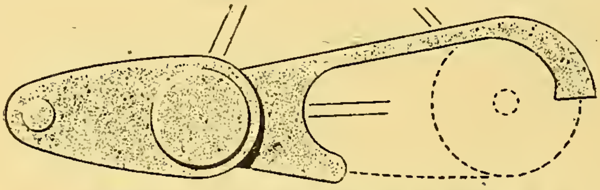
TRANSMISSION SYSTEMS.

Which is the Most Satisfactory?

WITH engines of improved torque, and with workshop practice and advanced knowledge in the use of metals, will the return of the normal order of things see the materialisation of the enclosed shaft drive? It is sincerely to be hoped so, and, viewing the matter from every point of the compass, there is really nothing to exclude its realisation, while there are a hundred reasons why every attempt should be made for its perfection. Its harshness has hitherto been its main stumbling-block, but the employment of an effective shock absorber rules this off the boards, and, in order to make clear its real desirability, let us first review the weakness of existing systems.

Pros and Cons of Chain Transmission.

The serious rival of the shaft drive is calculated to be the all-chain enclosed drive, which, when all is said and done, is far from being a desirable system. Chain cases are costly, difficult to make, and unwieldy. The employment of aluminium castings is the only solution to the problem. Mud and water are bound to find their way into the interior of the cases unless the design and workmanship are perfect, whereupon the casing merely answers the purpose of imprisoning the mud it contains.



A cast aluminium chain case giving total enclosure for front chain and partial enclosure for the rear—a design which "Chinook" holds up as vastly superior to total enclosure unless the latter be on the most costly lines.

Those who have made chain cases know the difficulties; those who have used them are poignantly aware of their shortcomings. The partially enclosed chain leaves much to be desired, but the next solo mount I have will possess, by preference, a countershaft aluminium front chain cover and an open rear chain efficiently shielded, as in sketch. This, in my opinion, is by far the most satisfactory arrangement for solo mounts, and unless manufacturers are prepared to part with the cash, and give us chain cases which will function properly as such, they will do well to give up all attempt at producing the truly weatherproof chain drive, and provide something which will allow us to inspect the chains. The sheet tin guards which to-day deface many excellent machines are a hopeless failure, and of all the enclosed chain drives to-day on the market there is only one (or two at the most) which offers any real return for its weight and encumbrance.

Chain-cum-Belt.

The chain-cum-belt system is worse. It is as harsh as the chain drive, slips when most desired to grip, and is a futile compromise as an engineering proposition. In fine, dry weather one blinds, with the result that one probably over-oils, and the front chain, being only partially enclosed and lubricated from the engine, similarly obtains an overdose, flings it on to the belt pulley, and the belt slips. In wet weather water gets on to the belt by hook or by crook, however good one's mudguarding may be, and—the belt slips. A watersplash inevitably holds one up, and, all things considered, the belt in any shape or form is, in my opinion, a relic of the dark ages, to be shed and left behind as speedily as possible.

Cost and Weatherproofing.

We have, then, two possible systems—the all-chain drive, in which no attempt is made at perfect weatherproofness, the front chain being enclosed in an aluminium cover and the rear chain merely partially enclosed (not necessarily so open as in American practice), and the all-enclosed chain.

The latter, to be really satisfactory, must be a good deal more costly than the shaft drive, while it is certainly heavier, uglier, and more cumbersome. It is far more susceptible to damage than the shaft drive, especially Overseas, while the shaft drive scores on the points of absolute weatherproofness, facility as regards perfect lubrication, longevity and neatness. Does any system present such neatness as an integral unit with its single shaft protruding, to be connected, by a castellated rod, to the simple grease-tight bevel gear box on the rear hub? Accessibility, cleanliness, and simplicity are salient features of the shaft, and though it may be regarded as a knotty problem, it certainly is no more so than is the oil-tight chain case; in fact, it may be regarded as the only system which renders such oil-tightness possible. CHINOOK.

REGISTRATION IN U.S.A.

In the United Kingdom the motoring registrations during the war have steadily declined. In the United States the reverse has happened. During 1917, which was America's first year of the war, there was an increase of 1,396,324 cars and motor cycles over 1916. The total registration in the United States on January 1st, 1918, was 5,000,000, which means that there is one motor vehicle to every twenty people in the country. Two years ago there was one for every forty people. In the British Isles the pre-war ratio was one motor for every hundred people.

OCCASIONAL COMMENTS

By "Ixion"

The Influence of Aero Engines.

A GOOD deal of impetuous nonsense has been talked and printed about the part aero engines will play in the evolution of motor cycles. urely the salient points are quite easy to grasp. Sub-ect to discussion, I submit that they are just two in umber, viz. (1) Aero engines have transformed our chnical knowledge of air-cooling. (2.) Various pes of aero engine suggest improvements in the otor cycle engine de luxe. As regards (1), traders nd users alike must grasp the fact that the half-ozen men who are masters of the design of air-cooled ero engines express the utmost contempt for pre-war otor cycle engines, considered as scientific efforts to et the best results from air-cooling. If this con-empt is not mere good-natured "swank," we may xpect all motor cycle engines to develop a higher fficiency after the war, and the little yarn anent a ertain "stunt" two-stroke, which I printed the other eek, indicates the practical values of these vague evelopments. This factor will influence the whole amut of motor cycling, and should be specially use-l in the lightweight sphere. Baby two and four-rokes should become far more practicable.

The Rotary a Wash-out for Road Work.

ON the other hand, most of the talk about radials and rotaries is probably hot air of considerable temperature and no great density. The rotary a hopeless dud from a motor cycling standpoint. o name a few of its worst blots, it suffers from short roke, acute connecting rod angularity, heavy piston ressure on the cylinder walls, absurd lubrication, aste of power in overcoming air resistance, difficulty silencing, external filthiness, low maximum r.p.m., tc., etc. It would never have been tolerated even n aircraft, but for certain obvious considerations hich balanced these glaring shortcomings *under the pecial circumstances involved.* The war created a emand for ultra-light engines, of great horse-power, mall overall diameter or "swing," and of the mini-num depth from front to rear. Air-cooling offered ttractions in such a specification. The design of a tationary air-cooled engine of enormous h.p. was not hen practicable—perhaps is not yet practicable. Hence the sudden war boom in rotaries. None of the bove conditions apply to motor cycles. The crudest ir-cooled design will give satisfactory results on a ehicle which demands no more than 3½ h.p.; which an make shift with an engine of low m.e.p.; which n normal use is hardly ever run on full throttle, and hat only for the briefest imaginable periods, and which is not at all closely limited in its overall dimen-ions. In my opinion, to put a rotary engine on a motor cycle would be the act of a lunatic.

What About the Radial?

THE radial stands in a somewhat different category. A correspondent treated the technical aspects of the rotary with ability in *The Motor Cycle* of April 4th last: but, to my mind, he completely missed the main practical issues. He was perfectly correct in laying some stress on the question of cost. It is really determinative so far as the bulk of commercial motor cycles are concerned; and in the impoverished world of to-morrow motor cycles as a class will surely tend to become cheaper in terms of £ s. d., or—if the financial situation renders that impossible—specifications will become less luxurious. Prior to the war some of us did not mind what we spent on a machine within limits, but surely it is an absurdity for an individual to spend a huge sum on a machine which is only capable of transporting one person and an extremely sketchy allowance of baggage. The five-cylinder radial must remain more costly than a vertical single or a V twin: and it is not likely to figure as the power unit of the motor cycle for the million. Our contributor, however, overlooked the fact that there was a very distinct and important market for motor cycles de luxe: that this market may revive after the war: and that the engine de luxe for the motor cycle de luxe has yet to be evolved.

Motor Cycle Engines de Luxe.

THIS Sybarite market falls into divisions: (*a*) bicycles; (*b*) cycle cars and sidecars. In the past the trade which coquetted with this market experimented with three types of engine—the big V, the flat twin, and the four-cylinder. The first was badly balanced, had an ugly-sounding exhaust (which really counts quite a lot), and proved inaccessible when jammed into a triangular frame panel. The second was only half exploited when war broke out: is really difficult to house in a motor cycle frame: and is not too readily accessible. The third was even more in its infancy—so far as small air-cooled examples were concerned—than the flat twin: from my experience its wee cylinder caused far more trouble than the bigger cylinders of the V and the flat twin: and accessibility was not one of its virtues. None of the trio had been established as the ideal engine de luxe. The radial is a new and formidable competitor in this special class; where cost within reason is of small account. Its cost disqualifies it for the normal market; I am not saying that a Henry Ford might not produce a five-cylinder radial to undersell all existing vertical singles: but, if Ford achieved this stunt, he could certainly undersell his own five-cylinder radial with his own vertical single. If we add a footnote to the above-mentioned article of April 4th, "The above arguments only apply to the market which can accept engines de luxe," we shall throw it into due perspective.

OVERSEAS SECTION.

A Commentary based upon Practical Experience and a Study of Overseas Opinions.

Tyre Notes. THERE is only one decision possible with regard to motor cycle tyres for use amidst pioneer conditions—that is, the largest and heaviest tyres and rims procurable are none too substantial, and anything smaller and lighter than the largest is apt to prove a source of never-ending trouble.

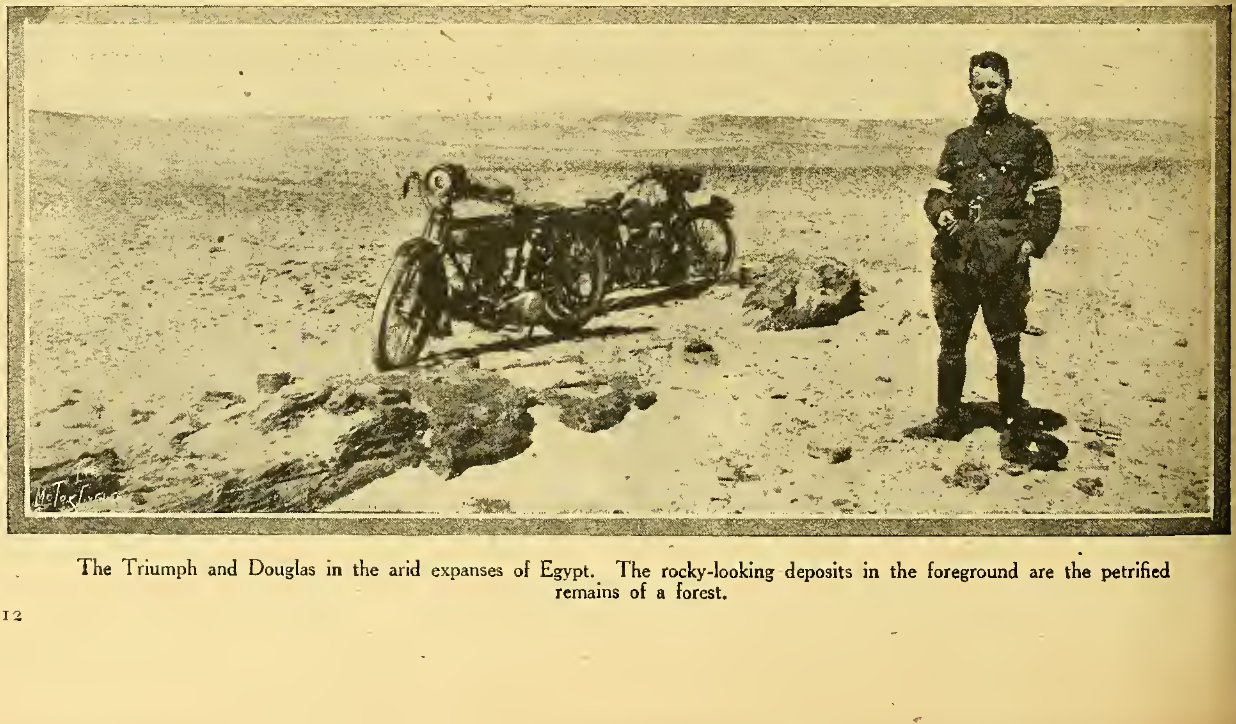
It is a foregone conclusion that 28in. wheels are preferable to 26in. wheels, both for solo and sidecar use, but a very large, "squashy" tyre on a 28in. wheel is not necessary, and is unsafe for solo riding. In sidecar use the best size is undoubtedly 700 x 80 mm., mounted on a flat voiturette rim. Voiturette rims are better for sidecar use, as they provide a greater width on which the beaded edge can lie flat. In solo use the 28in. x 3in. or 2½in. is a satisfactory size, the large wheel bridging the inequalities of the road while the moderately narrow tyre obtains a good grip, and does not roll about between the rim and the road surface as does a 700 x 80 mm.

There are two reasons why the above recommended size can be regarded as the smallest serviceable for sidecar use. A sidecar outfit is usually very much heavier than the solo mount, especially as regards the weight on the rear wheel, and if a 2½in. tyre be used it must be kept so tightly inflated to avoid bumping on the bad patches that one might almost as well be mounted on a solid tyre. Running a tyre board hard, as the makers generally recommend, may be all right as regards the longevity of the tyre, but it is bad for the machine, just as it is bad for the rider. The jolting effect of a board hard tyre on a bad road is terrific, not only tending to shake the whole outfit to bits, but imposing undue snatches on the transmission. We have ourselves heard of gear box troubles originating from the use of tyres so small that it was necessary to run them board hard.

The large tyre, on the other hand, can be run just so far relaxed that a cushioning effect is obtained from it, and, since side-slip need not be guarded against in sidecar use as with a solo mount, the slight rolling that occurs is of no consequence.

* * *

Sidecar Springing. WE would again urge upon makers of sidecars the desirability of employing some method of springing the sidecar wheel. Recently we received a letter discussing this question from a member of our staff now serving with a sidecar ambulance section operating in a hilly sector at the Front, and his opinion was conclusively expressed. Three of the sidecars in his section possess spring wheels, and quite apart from the very considerable comfort derived therefrom, the springing systems have proved the finest antidote for frame



The Triumph and Douglas in the arid expanses of Egypt. The rocky-looking deposits in the foreground are the petrified remains of a forest.

O rseas Section —

b akage yet arrived at. These three machines are t only ones in the section that have not, as yet, sust ned any frame breakages. Those having rigid w eels have all given trouble in this direction. C nerally, it is the chassis that breaks adjacent to its m st rigid part of attachment, and one can thoroughly r lise this state of affairs on contemplating the terrific b ws that are delivered upon the chassis when the s ecar wheel or the rear wheel of the motor cycle c nes into violent contact with some obstruction.

Our correspondent goes on, "If the makers of s ecars could realise what some of the wounded s fer during transportation they would not only fit s ing wheels but would also revise their whole s inging systems. Sidecars are worse in this respect t n they were five years ago—our stretchers being unted in much the same way as the ordinary touri g bodies. We want not only spring wheels, large t es, and good suspension, but in my opinion every s decar turned out, whether for the Army or home u e, should be fitted with a friction shock absorber erating between the body and the unsprung portion, so as to damp out the terrific rebound. With us it is necessary always to carry a man on the carrier to steady the stretcher—*i.e.*, prevent the rebound by the application of his hand, for it is this quick recoil and snatching motion which cause so much suffering to the wounded. Damp it out, and the stretcher rides perfectly."

Our correspondent is unquestionably right, and what applies in his locality applies with equal strength in all regions of rough roads. The tendency in sidecar springing seems of late to be to employ shorter and stiffer springs, which by no means give maximum comfort. That a friction shock absorber, placed as our correspondent suggests, would enormously improve matters, cannot be doubted, for even if the hood be erected the wind resistance acts in much the same manner, steadying the rebound, and thus adding to the comfort of the vehicle by preventing the springs from attaining their full range in either direction.

The sidecar de luxe, then, should possess a spring wheel, a well-sprung body, and at least one adjustable shock absorber; given these it would rival the Rolls-Royce for luxury of motion.

A Selection of Letters from Readers scattered all over the World.

English Machines in N.S.W.

Mr. J. H. Anderson, Nowra, N.S.W., comments as fl ows: "The article you published on mountain climbing i N.S.W. was illustrated by photographs taken by myself. e boy in the photograph is my brother, who has been led, hence this letter. We (he and I) have been most i erested readers of *The Motor Cycle* since we started with tor bicycles a little over three years ago; consequently were both delighted to see our own machines illustrated it. He said in a letter home that he had seen the page ile in France. I have often thought I should like to ngratulate you on your splendid journal. Unfortunately, ing to the submarines, several copies have gone to the ttom lately—one particularly, which I would have liked see, containing a description of the latest Brough.

'In the photographs sent my mount was the magneto gined Rover, which I used for nineteen months and then d for £87 10s. It cost me £110 new. I now have a gneto engined King Dick, put together by Messrs. Bennett d Wood, of Sydney. It is fitted with S.A. gear, and is a st serviceable mount, although not fast. I "barrack" for e English machine every time, but I do not know whence y next mount is coming, as there are no English twins ming out. I find it pays me best to use a machine for elve months or so and then sell, as one can always get a od price if one looks after the machine.

"I wish your journal the continued success which its to-dateness deserves."

American Machines in Canada.

Mr. W. R. Warne, Toronto, Canada, writes us again as llows: "In writing the letter which you kindly published October 25th, 1917, my sole motive was the hope of ousing some interest on the part of British manufacturers the Canadian motor cycle market. Whether I succeeded ems doubtful. Anyhow, the offer to furnish information, ith which I concluded, elicited only one solitary response. resumably, our friends of the trade are possessed of all rticulars, or was my charge of lethargic indifference more lly justified than I imagined?

"'W.G.,' late Triumph agent in Toronto, questions my sertion regarding the preponderance of American machines Canada. He then proceeds to remind me of a *pre-war* mpetition in which *out of seventy contestants only two, or ss than 3%, rode British machines.* Surely these figures nfirm my contention? I fear, moreover, that this very low atio would have to be considerably reduced were similar mparison applied to ordinary road conditions.

"Evidently, 'W.G.' did not read my letter very carefully. o far from 'swearing by American machines,' I am so little nterested in them that I have never ridden one. Furthermore, the remark that 'the $3\frac{1}{2}$ h.p. Triumph is regarded as a lightweight, fit for city use only, was clearly expressed as representing, not my opinion, but the impression prevalent among local riders. Again, I did not utter a syllable criticising either agents or British motor cycles. The former are helpless and deserve sympathy, and the latter command my unstinted admiration, it being my fervent wish that I may, as soon as circumstances permit, see them replace the American product in the affections of Canadian motor cyclists. This, unfortunately, is not likely to occur unless British traders wake up.

"'W.G.' suggests that English makers have lost money in attempting to capture Canadian business. I do not doubt this, but predict that their losses will continue unless they adopt entirely different tactics. They must realise that in 'entering the lists' for Canadian trade they have to engage in conflict with very doughty opponents. For each concern to attempt to establish one-man shows here and there is to invite failure.

"It seems to me that the only course at the beginning for those to follow who intend to compete with the Americans is to get together and work out some co-operative scheme, or, better still, form a subsidiary company with headquarters (showrooms, stores, workshops, and offices) in Toronto—the English centre as well as the commercial hub of Canada—branches in Montreal and the western capitals, and carefully select agents throughout the provinces. Special attention should be given to creating an efficient service system, and prices of spares and accessories should be protected."

Why no English Machines in the Far West?

A letter from Vancouver strikes a rather original note, and the writer—Mr. M. T. Eddie—has certainly succeeded in leaving us rather befogged as to how far he is in earnest. He says: "I have seen several copies of your paper, and must confess I have enjoyed them all, but do they really make motor cycles in England? I ask, because none ever seems to reach us out here, and if they are so good, so well finished, so powerful, and so reliable, surely we on this side, to say nothing of our 'Frisco neighbours, deserve to be given the chance to test and appreciate a good thing. And I have generally found that anything worth having is always to be seen and had in 'Frisco, but English motor cycles do not find a market there.

"It rather makes us think of how the Austrian Ambassador described to his Government American efforts for the war—'Two-thirds advertisement and the other third bluff.' That is what we think of English motor cycles, for we cannot understand why, if they are so good, we do not get a chance of proving their merit ourselves."

A NEW TWO-STROKE V TWIN ENGINE.

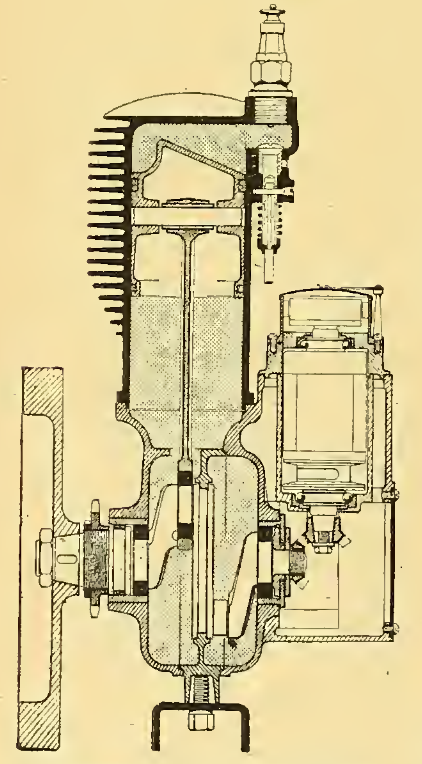
Incorporating a Magneto with a Vertical Armature, and an Ignition System in which the Engine Piston itself plays an Important Part.

IN spite of the stress of war, we frequently receive, even at the present time, particulars of new and interesting designs. Below we describe practically in the words of the designer—Lt. R. W. Richards, A.S.C., M.T.—what seems like a promising new engine and ignition system.

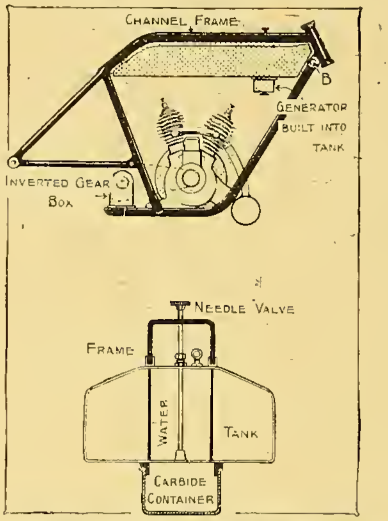
The engine is a V twin two-stroke, having the cylinders set at an angle of 45°, while the cranks are placed so that even firing, good balance, and even torque are obtained. The two crank cases are divided in half, and the two sides are rendered compression tight by a piston ring gland, which has proved to be quite successful in practice. There is practically no wear at this point as the ring is stationary, and there is little or no tendency to press against the side of the groove in the crankshaft.

The cylinders (which are 60 mm. × 60 mm.) are slightly staggered, so that the back cylinder has a better chance of keeping cool than if both were in line, while roller bearings are provided on the big ends and on both sides of the main shaft. The piston is provided with three rings—two at the top in the same groove and one at the bottom.

One of the most novel features of the engine is the arrangement of the magneto. The magneto is quite standard, so far as its essential features are concerned, but it is carried in a housing cast integrally with the crank case, and the position of the magnets relative to the pole pieces has been altered—that is to say, the armature, instead of running horizontally between the magnets, is placed vertically between them, the magneto being placed with the poles facing upwards. The magnets are a permanent fixture in the housing, so that if the magneto requires attention the armature and contact breaker complete may be removed, a keeper placed over the poles and the magnets left *in situ*. The drive is by means of a bevel, and, of course, is entirely enclosed in the housing.



Sectional view of the twin two-stroke engine, with "vertical" magneto, described in the accompanying article.



The construction of the channel steel frame and the acetylene generator arrangements.

Another point of interest is the compression release, which is direct acting, the valve being controlled by a Bowden cable, and there are no levers or links to cause trouble. It is so placed that when the compression release is opened cold air rushes on to the plug points.

It is intended that a Claudel carburetter should be fitted to this engine, which should render it quite flexible—in fact, an experimental machine built before the war with this type of engine showed great flexibility and economy.

The Frame Construction.

The frame, contrary to general motor cycle practice, is to be of channel steel, and the power unit, together with the gear box, will be mounted in the manner shown in the sketch. It will be seen that the crank case does not, according to usual motor cycle design, form a bridge or portion of the frame. This tends to greater strength, and also renders the whole power unit most accessible, so that it can be quickly lifted out and placed on the bench.

The cross section of the frame and of the tank shows the manner in which it is proposed to carry the acetylene generator. It will be noted that if the pins A and B are removed the whole power unit together with the gear box can be tal away without disturbing the adjustm of a single part.

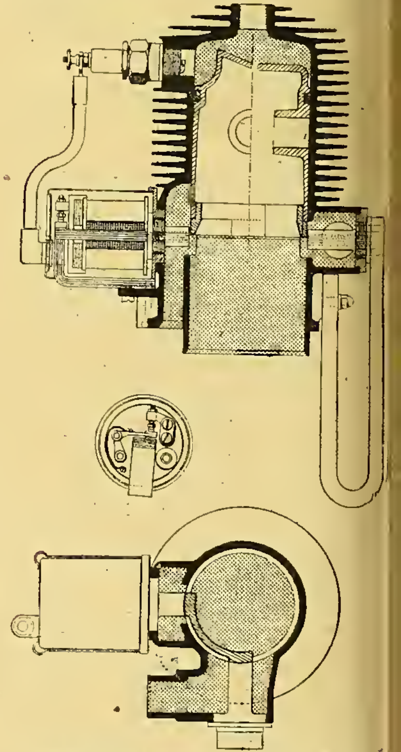
Such attempts as Mr. Richards made in his design to depart f standard practice with real improvem as the end in view most certainly dese encouragement, as motor cycle des has been far too prone to follow development of standard practice in past, and far too little originality been shown.

An Alternative Ignition System.

It is not only in the design of the eng that Mr. Richards's fertile brain has b working to bring about improvement.

In designing an alternative ignit system he has aimed at obtaining cheap, compact, high-tension igniter a two-stroke engine, the operation of timing of which is effected by the pist moving past the ports in the cylind thus doing away with the moving pa found in the ordinary magneto, and, course, the small amount of po absorbed in the magneto drive. In apparatus he has maintained the sa magnetic and electrical conditions as to be found in a stationary armature ty of magneto, except that the lines of fo in this case are cut by an inductor movi in an up and down motion instead of a rotational one.

In his endeavour to get rid of as ma moving parts as possible the designer



The ingenious ignition system shown in vertical and horizontal sections. (Inset) Details of contact breaker.

A New Two-stroke V Twin Engine.—

arranged that the contact breaker should be actuated magnetically, breaking the primary circuit at the proper instant—that is, when the maximum number of lines of force are passing through the coil. He has not yet actually tried this ignition device; and a magnetic contact breaker may be somewhat uncertain in its action, so he has conceived the idea of a mechanically operated contact breaker on the crankshaft, but he does not like the idea, as it would interfere with the beautiful simplicity of the original design. He pointed out to us that with the magnetically actuated device it would be possible to design the engine with an overhung crank pin, similar to the Veloce or experimental Levis, which would permit of easier stamping and machining of the crank for a roller bearing big end.

Piston Details.

The piston would be of aluminium alloy with a Swedish iron inductor attached to the skirt, for the two-fold purpose of directing the magnetic lines of force from the magneto through the core of the small coil and for conducting the heat away from the piston head more quickly.

The ignition is, of course, timed by the passage of the piston over the gas ports in the cylinder, and is thus made definite. An ordinary magneto has to be driven in order that the armature may cut the lines of force in the magnet, and this means that chains, chain wheels, platforms, adjustment, and fixings are necessary, while the weight must also be taken into consideration, but with this scheme the means to cut the lines of force are provided by the piston, which performs the same functions as an ordinary two-stroke piston, except that the inductor in the skirt controls the output of current in addition to controlling the inlet and outlet of gases in the cylinder.

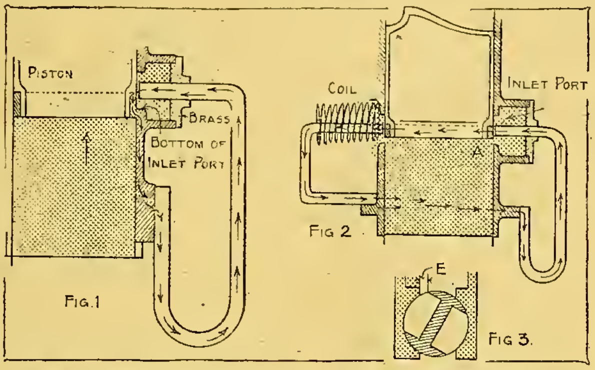


Fig. 1.—The direction of the lines of force just before the piston uncovers the inlet port.

Fig. 2.—The direction of the lines of force when the piston has just passed the bottom of the cylinder port. This position corresponds to that of the armature in an ordinary magneto, as shown in fig. 3.

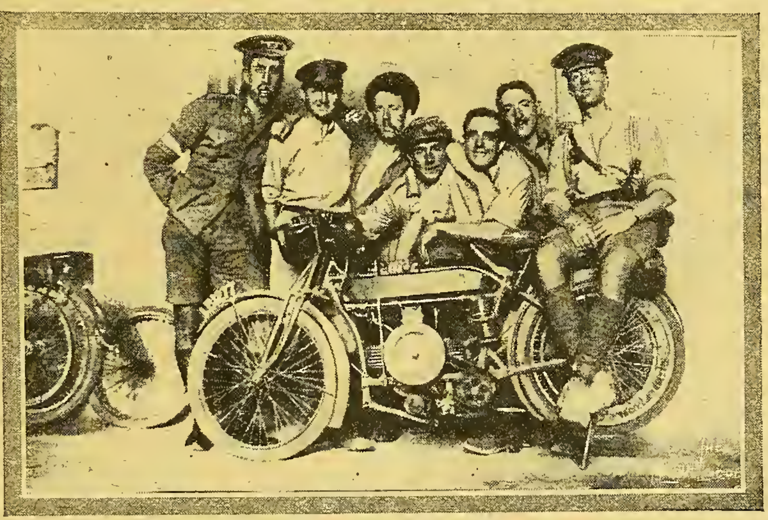
The most vital parts of the system—that is, the high-tension coil and the contact breaker—are situated in a dry place, behind the transfer port, and the only other criticism which we have to offer besides that of the magnetic contact breaker is that the high-tension winding would be, we fancy, rather too much subjected to heat from the engine, and would necessitate very careful insulation of the core winding; but these two points have not escaped the attention of the designer.

Another point of interest is that no accurate machining would be required to obtain a small air gap round the armature, as this is accomplished by the ordinary course of making the piston a correct fit in the cylinder. Moreover, the timing cannot slip. If the stroke is increased and the inlet port is made deeper, the firing point is brought about the same angle early as with the shorter stroke. Thus, no matter whether the stroke is long or short, the firing point is not affected.

◆

FINE GAUGE WORKMANSHIP.

MANY manufacturers of motor cycles make a boast of the fact that they work to an extremely fine limit throughout the manufacture of their machines. This principle, of course, is excellent, but it would be a thousand blessings if they would aim at a design that would not necessitate an extremely fine limit. If the design is such that extremely fine workmanship is necessary, then the machine, whatever it be, will not wear so well as one which is so designed that fine workmanship is not necessary. Let us employ limit gauges, by all means, but do not let us depend upon them for the reliability and longevity of our machines, so that, immediately the initial newness and perfection of fit wears off, new parts are necessary. I do not refer so much to engines. In any reciprocating machine fine workmanship is essential, but there are other units in the construction of a otor cycle where it is not essential. ke, for example, the gear box. cently I have seen a good many gear xes—all of the same design, ample, omy, and, in many respects, of excel- nt design. But, under the conditions warfare, they have given trouble—simply because the designer of the box has not allowed a sufficient margin for wear. The dogs are too shallow, the striking mechanism too accurate, and the necessity for fine workmanship too painfully present in every part. The result is that, immediately the initial newness—I had almost said stiffness—wears off, trouble begins. We usually reckon that they wear four months, after which period it is necessary to renew the dog clutches; at the end of seven months they must be renewed again; and at the end of nine months the wear throughout the box, though not great, is sufficient to render it of little use to renew odd parts. It is necessary then to overhaul thoroughly the whole gear box.



A merry group of despatch riders in a garage in the Suez Canal zone.

These gear boxes are amply roomy for a wide margin to be allowed for wear, so that, when the parts become somewhat slack, the reliability of the unit is not endangered; and these facts apply not merely to one individual make, but to almost all. There is no reason why such an article as a gear box—and the same applies to other units—should not wear indefinitely, its life being determined, first, by the allowance made for wear in its design, and, secondly, by the quality of the material of which it is made.

It is up to the designer, then, to get away from the vital necessity for fine workmanship, and, by so doing, he will not only produce a more reliable article, but he will be able to produce it at a lower price.

Price alone should prove an adequate incentive for making the change, even if there were no other advantages to be gained.

H.M.B.

RECOLLECTIONS OF AN OLD FAVOURITE.

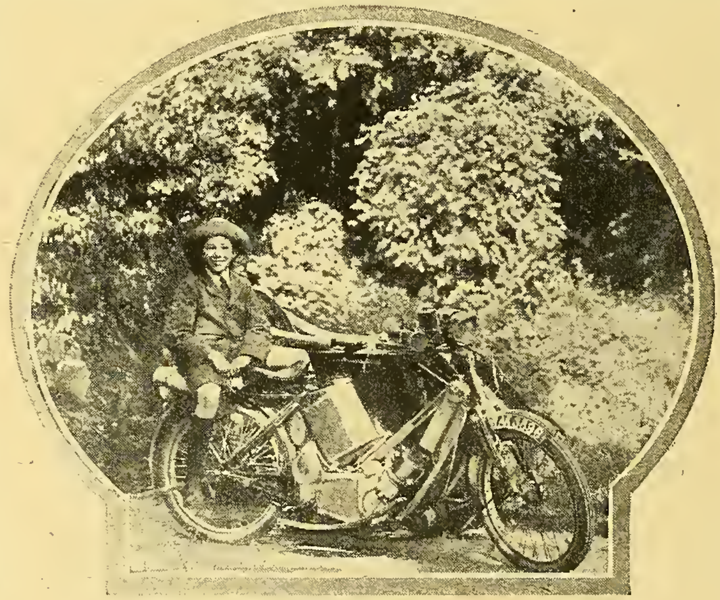
An Appreciation of a Motor Cycle which appeals both to Expert and Novice alike.

ONE needs, perhaps, to be a bit of a specialist in order to appreciate a Scott motor cycle to the full. Like absinthe and other inequalities in life, it grows on one. Perhaps because of its superlative comfort and sheltered riding position, perhaps because of its delightful control and balance, or perhaps because rule of thumb tactics simply do not apply in the case of the Scott, I have always regarded it as my favourite among a chosen few. A certain wily flat twin, a 2¾ h.p. T.T. single, and indeed one T.T. 3½ h.p. single—a type which to-day I eschew—are all fragrant memories, yet of the many scores of machines I have possessed—personally or on extended journalistic trials—the Scott affords the happiest recollections.

I do not mean to infer that such possession was an unblemished field of daffodils—far from it. If the water boiled it was merely a little diversion by the way. Why did the water boil? One recalled that all last winter one had ridden without a front wheel mudguard, owing to the latter having dropped off late in the autumn—and on what machine but a Scott could one do such a thing?—and that even with the radiator chock full of mud the water had never boiled. Why, then, should it boil this fresh April evening?

Probably one never found out. It never did the same thing again. That is the delightful part about a Scott. One concocts one's own little theories for the wayside mysteries that crop up, and in the meantime they automatically vanish.

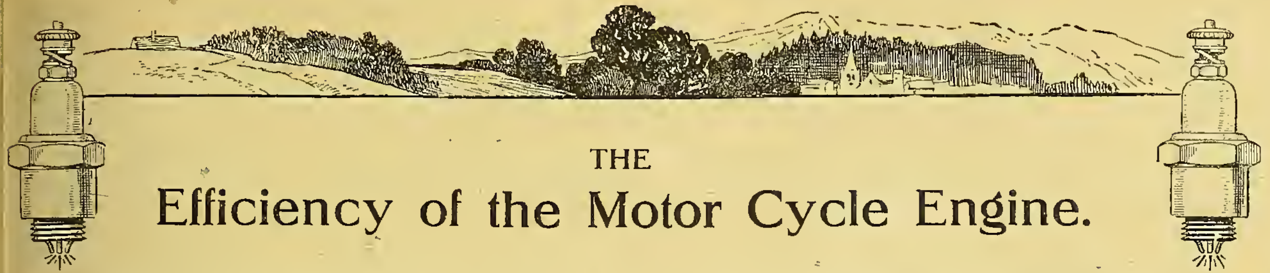
The Scott machines I have possessed all afforded endless incident and endless scope for exercising one's skill as a tuner. No machine yields a better return for careful tuning, adjustment, and alignment, but in the hands of an uninitiated rider a Scott can give trouble. It is a sportsman's machine, and if given gentlemanly treatment always responds in a gentlemanly manner. Endless attention is not necessary, as the following will prove.



The Scott combination on which some of the writer's most enjoyable experience was derived.

In 1912 my mount was a Scott, and that last happy possession certainly did not receive the attention its breed demanded. At the time I was very intimately associated with the outdoor press, and life was an absolute hurly-burly, spent chiefly on the road between Scotland and the West Riding—mountainous roads for the most part, fog, rain, and sunshine. Journeys of 130 miles per day were regular—500 miles per week in straight trips, as a rule—with a few twenty and thirty mile spins thrown in. The Scott was never cleaned, never tuned. The chain alignment and tension were carefully watched, and the oil-can used liberally. No time for anything else. Rust accumulated, things dropped off, the mudguards rotted from their anchorage, there was nothing left of the horn but the trumpet, and one of the footboards was missing. The makers hid their blushes, and implored me to submit the machine for an overhaul, but not much. I could pin my faith absolutely to that Scott, and trust to keeping timed appointments, but not so on a borrowed mount. I knew I could always start third kick, day or night, and reach my journey's end without fatigue—two points of very great importance. And so I kept on riding it till the silencer dropped off, till one could fit threepenny bits into one or two of the engine bearings, but still no breakdown. That, then, shows that, though a Scott responds to decent attention, and must, under any circumstances, be understood by its rider, it can be set down as a mount of unwavering reliability.

It must be borne in mind that this machine has remained unchanged save for minor refinements for some years, and that in the post-war model present weaknesses will probably be eliminated. It is to be hoped that more substantial bearings will be employed and a perfected system of lubrication. Personally, I regard the Scott as a most delightful machine, and one which appeared years before its time, and I look forward to its further development with the keenest interest. C



THE
Efficiency of the Motor Cycle Engine.

IN view of the present interest displayed on the value of the various fuels which can be used in connection with internal combustion engines, the following remarks may prove of value in showing what a remarkably small fraction of the theoretical or ideal h.p. can be obtained from the most modern type of motor cycle engine.

The first thing to consider is the ratio of the theoretical amount of work it would be possible to get from a given engine to the actual amount. This is called the *thermal efficiency*. It is now necessary to define two things in determining thermal efficiency:

1. The British thermal unit, which is the amount of heat required to raise the temperature of 1 lb. of water at its maximum density (*i.e.*, at 39° F.) through 1° F.

2. Calorific value. The calorific value of a substance is the number of British thermal units (or B.Th.U.) which will be liberated by 1 lb. of the substance when it undergoes complete combustion.

Now the calorific value of ordinary commercial petrol is about 20,000 B.Th.U., and as 1 B.Th.U. is the equivalent of 780 ft.-lb. of mechanical work, 1 lb. of petrol should, if all the heat be used up, give 780 × 20,000 or 15,600,000 ft.-lb. of mechanical work.

Supposing the engine consumes .6 lb. of petrol per b.h.p. per hour (which is a good average), then .6 × 15,600,000 or 9,360,000 is the number of ft.-lbs. of mechanical work done. Also a horse-power is the power exerted to raise 33,000 lb. one foot in one minute, or 33,000 × 60 or 1,980,000 ft.-lb. per hour, then the ratio $\frac{1,980,000 \times 100}{9,360,000}$ is the actual thermal efficiency—*i.e.*, about 21%.

Thus, approximately, only one-fifth of every gallon of petrol used is converted into useful work, the rest bringing about overheating, burnt valves, sooted plugs, and other attendant troubles well known to the motor cyclist.

So much for the losses due to the improper use of fuel.

The next question is that of indicated horse-power.

It is obvious that this is some function of the force exerted on the engine piston during the working stroke (in the case of a four-stroke engine) and the distance travelled by the piston in feet per minute.

If D = diameter of the piston in inches,
s = stroke in feet,
n = number of revolutions per min.,
P = average pressure exerted on the piston,

then the force exerted on the piston is

$$\pi \times \left(\frac{D}{2}\right)^2 \times P = .7854D^2 \times P,$$

and the distance travelled by the piston is $2sn$.

Now since the power is only transmitted to the piston through one stroke out of the four, we must divide the product of these two quantities by 4, thus—$\frac{.7854D^2 \times P \times 2sn}{4}$, and for normal running the distance travelled by the piston ($2sn$) is about 1,000 ft. per minute, and P the average pressure on the piston is about 80 lb. per sq. in.

The i.h.p. is then equal to

$$\frac{.7854D^2 \times 80 \times 1,000}{4 \times 33,000}, \text{ or } .47D^2.$$

For an average single-cylinder engine D is equal to 85 mm. or 3.34 inches, so that its i.h.p. is $.47 \times (3.34)^2$ or 4.72.

Now according to the well-known rating, the brake-h.p., or the h.p. exerted under load, is taken to be only 80% of this value, which then becomes 3.77 b.h.p., which is probably what a good 3½ h.p. (nominal) single develops.

From the foregoing remarks an interesting comparison of fuel value can be got by noting calorific values, which for the most common fuels in present use are:

Paraffin	21,500 B.Th.U. per lb.
Benzole	18,000 ,, ,,
Alcohol	10,000 ,, ,,
Coal gas, about ...	550-650 B.Th.U. per cu. ft.

It does not, of course, follow that the fuel with the highest calorific value is the best to use in connection with internal combustion engines, and very frequently their combustion is attended with the formation of other compounds which may interfere considerably with the mechanical efficiency of the engine. For instance, paraffin, even in the best circumstances, is likely to leave a large deposit of soot which, besides clogging up various parts of the engine, becomes incandescent during continuous running, seriously pitting and burning cylinder, valves, piston, and exhaust pipes.

The question of efficiency has only been discussed as far as the power delivered to the crankshaft is concerned, as the losses in the transmission on a modern motor cycle are quite small.

The chain, of course, is the most efficient form of transmission, and if well lubricated is often as high as 98%. With the belt, however, it is probably only 80%, as the useless work done by the engine in conforming the belt to the engine pulley is considerable. This is quite easily understood when one tries to bend a length of 1in. belt normally in contact with the pulley round its periphery. The efficiency of the shaft is a very variable quantity, and, of course, normally involves that of two pairs of bevel pinions. Generally, it is in the neighbourhood of 93%.

W.K.A.

Times to Light Lamps.

SUMMER TIME.

April	25th	8.39 p.m.
,,	27th	8.41 ,,
,,	29th	8.46 ,,
May	1st	8.50 ,,

Water Cooling.

The improvements made in air-cooled engines during the war may retard the development of the water-cooled motor cycle.

Post-war Demand.

Provided fuel is available at a reasonably low price, it is anticipated that the post-war demand for motor cycles will be many hundred per cent. greater than it was before the war.

The Spring Frame Problem.

Closely allied to the problem of the spring frame on a chain-driven machine is the question of ratio of sprockets of the final drive. The sprockets should be of equal size.

April Days!

The weather during the week-end was most remarkable, even for our undependable climate. First rain, then snow, and afterwards more rain fell for thirty-six hours or so. In happier days the weather would have done something towards marring several sporting events, but we imagine that this time it made but little difference to motor cyclists.

Imports and Exports.

As was the case in February, only one motor cycle was imported into the country last month, its value being £31. Tyres and accessories were received to the value of £3,488. Compared with the imports of March, 1917, there is a decrease in total imports of £40,721.

EXPORTS.

Exports show a decline compared with the corresponding month last year, as might be expected :

	1916	1917	1918
Number of machines	1,093	988	258
Value of motor cycles, parts, etc.	£80,328	£78,850	£32,593

The New Army Type Indian.

The first of the new Army type Indian motor cycles was seen in London last week. Six foot of khaki-clad Sammy, with the engineers' hat cord (red, piped with white), was piloting it through the Strand. He did not seem to find much difficulty in insinuating it through our dense traffic, for all its right-hand sidecar. The outfit was finished in a very pale khaki, almost cream, and the Indian name on the tank was done in bold but inconspicuous coloured lettering. The sidecar body was very ugly in outline, but serviceably constructed, and the chassis was secured by five extremely hefty-looking connections. The equipment was entirely American, and embraced none of those concessions to European taste with which we are familiar. The saddle was a Troxel, rather strangely shaped, and of the colour of a buttercup. Compressed gas lighting, and Remy ignition, so far as could be gathered, completed the equipment.

Workhouse as Motor Cycle Repair Depot.

"The Workhouse," as it is still known, at Grove Park, near Bromley, has certainly seen some changes since the earliest days of the war, when it was a mobilisation depot for several hundred motor 'buses and impressed lorries. Since then thousands of M.T. drivers and despatch riders underwent training from the depot, which later became the discharge depot for A.S.C., M.T., men invalided out.

Now it is a Women's Legion depot, and a number are seen on motor cycles and sidecars (P. and M.'s, etc.), and doing work formerly performed by cars. Part of the workhouse has recently been equipped for motor cycle, car and tank repairs. A four-cylinder car engine provides power. Most of the motor cycles used by the women riders in the London district receive attention here.

Special Features.

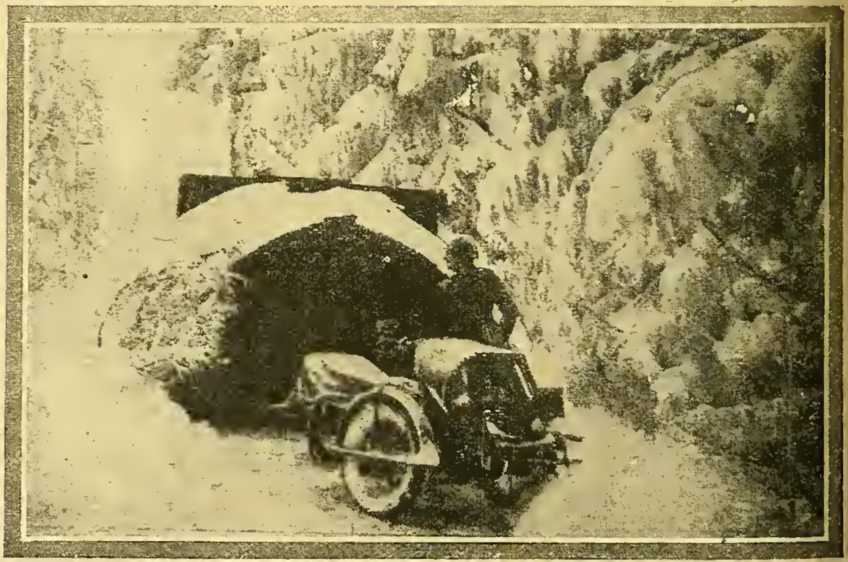
A NEW TWO-STROKE ENGINE.
COMFORT IN RIDING.
EFFICIENCY OF THE MOTOR CYCLE ENGINE.

Motor Cyclists Wanted.

The County of Middlesex Motor Volunteer Corps, Central Group, requires a number of motor cyclists to bring the corps up to full strength. The work they will have to do is of a very interesting and important character, and cannot fail to attract every keen and patriotic motor cyclist. Full particulars can be obtained from Mr. K. Ballard, County of Middlesex Motor Volunteer Corps, Central Group, 406, Euston Road, London, N.W.1.

Woolwich Sale of "Unserviceables."

An auction sale of "unserviceable" ordnance stores, advertised to take place this week at Woolwich, includes three motor cycles, a car, eighty-three magnetos, 2,500 outer covers, and hundreds of tons of old wood, iron, rope, canvas, and rubber. A correspondent says that the motor cycles are probably disabled and ancient "war worns." At the last sale one "lot" was an ancient tricar. The sale opens on the 25th inst. at the Co-operative Hall, Parsons Hill, Woolwich.



A striking photograph taken on the French Front, showing the conditions under which the sidecar ambulances work. The driver of the Sunbeam ambulance at the mouth of his dug-out is a late member of the staff of *The Motor Cycle*.

F ur Cylinders?

Vhich will be the next British motor c le concern to introduce a *de luxe* four-c inder machine?

E ctrical Equipment.

An electrical expert predicts that the r tor cycle of the near future will have a combined ignition, lighting, and start-i set.

S e of War-used Motor Cycles.

At a sale held in Paris on the 8th i t., a number of motor cycles were p up for auction, and fetched various p ces ranging from about £3 up to £19. A British machine (a Royal Enfield) f ched the highest price, a Moto-Rêve c ning second, and a Motosacoche third. venty-five sidecars were knocked down a less than £1 each.

M ed Metaphors.

The following sentence occurred in an a icle recently sent in to us by one of c most popular and respected con-t butors: "To do so is merely like p ting new cloth into an old bottle, for t new part finds any weak spot in t old and the rent is made worse." S cely Mr. De la Roche, M.P., must b either turning in his grave or going g en with envy!

M tor Cycles Help the Shortage of Doctors.

So many doctors have been sent Over-s s to join the Army that there is a great shortage of medical men in ronto. A military court of enquiry s recently held to investigate the state affairs, and it was finally decided to ure two Indian motor cycles and side-s for the use of doctors in making t ir calls. These motor cycles are rowed from the R.F.C. and are driven members of the Canadian Army edical Corps. In cases of emergency sidecar outfits may be employed in ing patients from homes to hospitals. ore motor cycles will be provided in e course by the military authorities.

Racing Classes after the War.

As the 500 c.c. engine may be dropped by the majority of firms in favour of the slightly larger engine, will the T.T. and Brooklands racing classes be revised to suit the altered conditions?

Infinitely Variable Gears.

The infinitely variable gear for motor cycles is a fascinating problem to many inventors, and so long as we have motor cycles on the road there always will be cropping up designs for variable pulleys, friction gears, and hydraulic clutches.

Six-cylinder Motor Cycles.

At least one private designer has a six-cylinder V engine in course of construction. So far the time consumed on the work amounts to 163 Saturday afternoons and fourteen Sunday mornings. The cylinders are 60×60, the total capacity being 1,020 c.c., and the complete engine will occupy less room in a frame than would a four-cylinder Henderson.

A Motor Cycle "Coal Cart."

In Norwich, Connecticut, in the early part of this year there was a coal famine, and for some time it was impossible to buy coal in quantities exceeding 100 lb. or 200 lb. per family at one time. The retail dealer could not, of course, undertake to deliver such small quantities. An Indian motor cycle agent in the town had an idle sidecarrier outfit of this make, and it then occurred to him that he could be of some service to the community, and he announced that he could deliver small quantities of coal for a nominal sum. The "nominal sum" each customer paid for the delivery not only paid all the working expenses but left quite a considerable amount as profit. It also was a good advertisement for the agent, and there is no doubt that hundreds of the inhabitants of the town now testify to the value of his services and the efficiency of the machine, which ploughed faithfully through the very worst of the winter weather, bringing relief to their cheerless homes.

The Ultra-lightweight.

Who will be the first designer to produce a 60 lb. motor cycle?

Engine-gear Unit.

At least one flat twin enthusiast has succeeded in embodying a change speed gear within the crank case of a flat twin—on paper.

Types.

Generally speaking, all motor cars follow the same practice except in minor details. In motor cycles one can almost say that no two are alike.

Road Schemes.

Several municipalities have town re-planning schemes under consideration, and no doubt the question of motor traffic will be considered in due proportion to its importance.

The Lady's Machine.

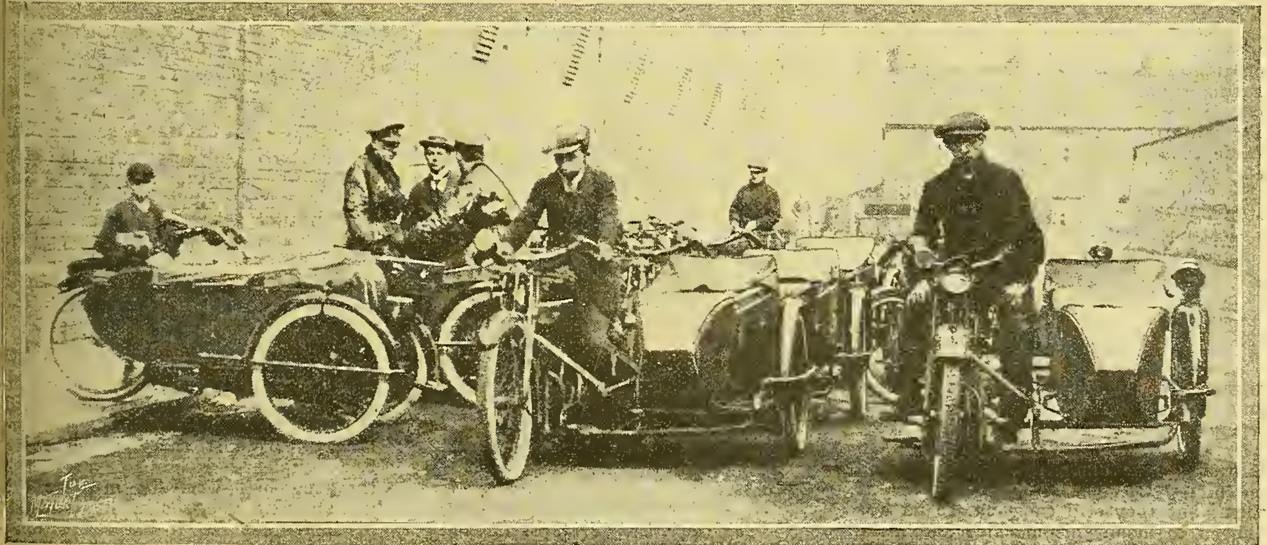
The lady's model of the future probably will be more a specially designed machine than an adaptation. There are now sufficient numbers of fair riders and potential riders to induce designers to give them attention.

New Blood.

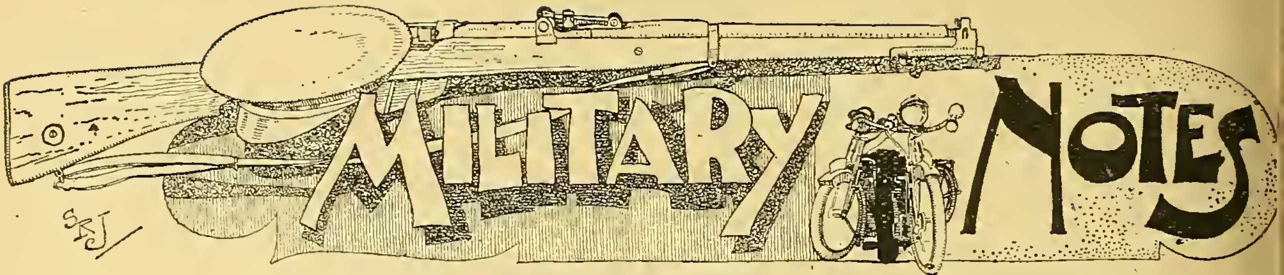
The war has brought into the motoring world quite a large number of men who may never have been interested in a motor vehicle. Men of many trades are in the R.A.F., and quite a large number will endeavour to retain their connection with the internal combustion engine.

Motors at Holiday Resorts.

A correspondent, recently in North Wales, informs us that that motorists' happy hunting ground is now almost pathetically bare of any form of motor other than the regular 'buses. In Llandudno, for instance, he saw on an average, one car per day in ten days. Last year, at Easter, the average was more like one hundred than one, in spite of current restrictions.



A group of 4 h.p. Douglas sidecar outfits, destined for war service, about to undergo a road test before delivery. Mr. S. L. Bailey, of Douglas Bros., is seen in conversation with the two officers in charge of the test.



A Calling-up Muddle. Belgian Honours for Motor Cyclists.

THE AUSTRALIAN METHOD.

ELIGIBLE men in the Australian Government Department are to be replaced by returned soldiers.

* * *

BRAZIL COMES IN.

A NUMBER of Brazilian officers and soldiers are demanding permission to form part of an expeditionary corps to fight on the French front.

* * *

LOST PARCEL MAILS FOR MALTA.

THE Postmaster-General announces the loss at sea, through enemy action, of parcel mails for the hospitals and fleet at Malta, containing parcels which reached the General Post Office, London, for despatch about February 20th last.

* * *

QUEEN MARY'S W.A.A.C.'s.

AS a mark of Her Majesty's appreciation of the good services rendered by the Women's Army Auxiliary Corps, both at home and abroad, the Queen has been graciously pleased to assume the position and title of Commandant-in-Chief of the Corps, which in future bears the name of Queen Mary's Army Auxiliary Corps.

* * *

MOTOR CYCLING ELECTRICIANS' CALL-UP CANCELLED.

AN example of man-power muddling was provided recently at a famous electrical firm in the S.E. district, where a number of skilled employees, including electrical tool makers engaged on magnetos and other electrical fitments, received a call-up to report at short notice for military service. The firm at once made representations that the men were engaged on urgent and vital work, and the call-up would result in the entire stoppage of important work. The notice was at once cancelled.

* * *

MOTOR CYCLIST CHASED BY AIRMAN.

THE *Daily Mail* correspondent recently met a transport waggon which had been machine-gunned by an enemy airman and a motor cyclist who had had an encounter with the Germans. He was trying to rescue two wounded A.S.C. men who had been hit from the air, when Germans came along the road and fired on him. He emptied his revolver at them, but they still came on, so he was obliged to mount his machine and make off all out. It is not often that a D.R. goes into action, and such a contingency is only possible in open warfare.

THE TOLL OF WAR.

ONE of the many gallant officers who have given their lives for their country in the recent offensive is the late Maj. S. J. B. Lacon, Royal Warwickshire Regt., attached A.S.C., M.T. He joined the Forces as soon as hostilities broke out, serving as a despatch rider in the Royal Warwickshire Regt. when defending the east coast, and later was granted a commission, and became attached to the A.S.C., M.T., on account of his extensive knowledge of motoring.

Lacon was a member of a well-known Norfolk family, was educated at Eton, and from his very schoolboy days took a lively interest in motor cycle matters.

He had a curious meeting not very long ago while at the Front. Lt.-Col. D. F. Nicholl, a vice-president of the A.C.U., who is in command of a heavy artillery group, wrote and told us that he had come across an enthusiastic motorist in the M.T.—"an A1 officer," to use his own words—who was the major in charge of the transport which served his guns with ammunition, little realising that he had found in the said major (who was, of course, Lacon) a distant cousin.

After his early motor cycling experiences, Lacon became more and more enthusiastic over motoring, and largely forsook the motor cycle for the car, though he never entirely gave up his old love, having owned a $2\frac{3}{4}$ h.p. New Hudso just before the war. He became inte ested in a garage in Ahingdon, in co junction with his brother, and took u the agency for Palladium cars, on whic vehicles he achieved considerable succe in competitions on Brooklands track. H was a fine fellow, a capital sportsma and very popular. His work in th A.S.C., M.T., was excellent, and hi rapid promotion was a clear testimon of this.

The late Major S. J. B. Lacon, Royal Warwickshire Regiment, attached A.S.C.,M.T. He joined the forces as a despatch rider in the former regiment.

* * *

DISCIPLINE!

IN the battalion orders of a famou regiment, under the heading of "Di cipline," it is stated that "men's hai will be cut evenly all over the head, an a fringe is not to be left in front."

* * *

CONTROLLER OF TRENCH WARFARE.

THE Minister of Munitions ha appointed Brig.-Gen. Arthur Asquith, D.S.O., to be Controlle of the Trench Warfare Department of th Ministry in succession to Maj.-Gen. T. M. Bridges, C.M.G., D.S.O., employe on special duty.

* * *

HONOURS FOR MOTOR CYCLISTS.

THE following Army motor cyclis have received the Croix de Guer from the King of the Belgians Cpl.-Motor-Cyclist E. J. Abbott, R.E Cpl.-Motor-Cyclist G. A. Bellamy, Sgt Motor-Cyclist H. Pennington, R.E., an Cpl.-Motor-Cyclist T. Philbrin.

* * *

BELGIAN RECRUITING BOARD

BELGIAN subjects who have bee posted by the Belgian Recruitin Boards or Appeal Boards to Gro 5 will enter active service on June 1s 1918. Those who have not by May 15t 1918, received their calling-up pape should inform Le Service de la Mobilis tion, 8, Lupus Street, London, S.W.1.

* * *

A DESPATCH RIDER'S BRAVER

AN example of bravery and fortitu is afforded by Pte. William Griffi Carnarvon, now in a Lond hospital. Whilst carrying despatches bomb exploded within six yards of hi throwing him from his machine. N withstanding the shock, he crawled his hands and feet to his destination a delivered the message safely, subsequent tumbling in a helpless condition into friendly dug-out.

THE MOTOR CYCLE
AVIATION SECTION

The enormous importance of the Air Service needs no emphasis: it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouraging of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

A Gallant Frenchman.

Lt. Foncb, a French airman, has achieved his twenty-seventh victory.

◆

The First Mechanically-propelled Aeroplane.

The first aeroplane to fly by mechanical propulsion was made by an Englishman named Henson, who in 1843 flew under the power of a 20 h.p. steam engine.

◆

Keenness.

An officer who had but recently been in receipt of his commission, and before joining the Army was in a West End business, was on leave in London when the offensive started. Since he could not find means of returning to the Front quickly enough by the usual train and boat route, he proceeded to the nearest aerodrome, and there found a pilot who was taking a machine across to France; thus he obtained a lift which brought him back to his regiment the same night. The curious part of the story is that he had never been in an aeroplane before.

◆

On Streamlining.

Why do not our designers pay much more attention to the very important point of streamlining? The Huns have done so with marked success. At present many of our machines leave much to be desired in this respect. A certain machine of French make, when redesigned and properly streamlined, increased its speed 10-15 m.p.h.; and the same h.p. engine was fitted in both cases. The original machine had quite a good streamline, too.

One cannot help wondering at the intricacies of some people's minds, on seeing a machine with the engine in a neat cowling tapering almost to a point, and no "pot" on the propeller to give harmonious lines throughout!

An Early Bird.

Archytas (400 B.C.) is said to have made an artificial bird of wood, which flew by flapping its wings, but no further details have been handed down concerning it.

◆

AIRMEN MOTOR CYCLISTS

The name of Lt. Ivan B. Hart-Davies, R.F.C., who was killed whilst flying last summer, will be remembered by thousands of motor cyclists. Hart-Davies was an enthusiastic motor cyclist and the holder of the John-o'-Groat's and many other long-distance records. He also competed in the Tourist Trophy Race of 1912. His records were accomplished by the aid of a wonderful vitality, combined with determination to wrest the coveted record from all comers. He was a most successful business man, a thorough sportsman in every sense of the word, and was probably one of the oldest pilots to obtain his "wings" during the war.

Lt. Ivan B. Hart-Davies, R.F.C., who was killed whilst flying.

An Appointment.

Mr. Bertram Jones is appointed Civil Assistant to the Controller-General of Equipment in the Air Ministry.

◆

Honour for Chatham.

Capt. McCudden, V.C., D.S.O., M.C., M.M., the airman, is to be presented with a testimonial by the borough of Chatham, of which town he is a native.

◆

New Chief of Air Staff.

Maj.-Gen. F. H. Sykes, C.M.G., has been appointed Chief of the Air Staff, Royal Air Force, on the resignation of Maj.-Gen. Sir Hugh Trenchard, K.C.B., D.S.O.

◆

New German Aeroplane.

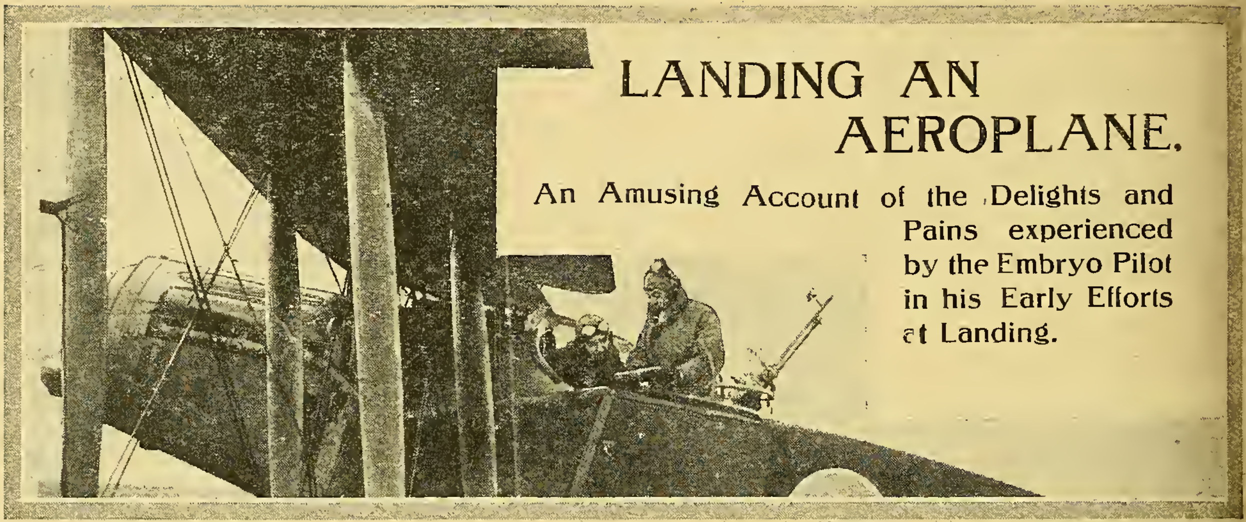
A new German aeroplane, Pfalz III., has appeared at the Front. It is a single-seater chasing machine, and is less than 30ft. wide with its wings spread. Its *débuts* were not lucky, as it appears to lack ascension speed. Two Pfalzes have already met their fate.

◆

The New Uniform.

Several people have been seen wearing the new uniform, and opinions are various. The loss of the Sam Browne belt is universally deplored, as nothing looks smarter, though it may be a bit of a nuisance. The jacket is merely a militarised golfing coat. The hat is quite the best part of the whole, with its elaborate gilt badge.

How many people will wear turned down trousers? Will the dictates of fashion prove stronger than all the Orders in Council ever printed—let A.P.M.'s come in their thousands? Blue trousers do not look so bad turned down, but khaki——! It may be news to some even now that "slacks" are supposed to be worn "unturned up."



LANDING AN AEROPLANE.

An Amusing Account of the Delights and Pains experienced by the Embryo Pilot in his Early Efforts at Landing.

FLIGHT has many surprises for the motorist. The first and perhaps the greatest of them is that landing, which looks so safe and easy, is the trickiest part of the whole business. It is not every motorist who can judge distances so beautifully that he can bring a fast car to rest at a given point without using his brakes.

In bringing an aeroplane down to earth we have, first of all, to judge our height approximately at the commencement of the slanting glide which is intended to touch ground where a good run-off will be left. Then we have to make this glide dead in the teeth of the wind, if possible; partly that the wind resistance of the planes when flying speed is lost may give us some braking effect, but more lest a puff of side breeze at the last instant may jolt the machine at right angles to her gliding path, and rip off the splayed undercarriage sideways. Finally, we have to flatten out of the glide at the last moment: and to time this perfectly is almost a matter of inches. If we leave it much too late the 'bus will stand on her head at 50 m.p.h., cartwheel over on to her back, and very possibly kill her crew. If we leave the flattening out a little later still, she will concertina her nose, and not improbably impale the pilot on the crankshaft. If we flatten too soon, she will flop to ground with a bump which will bash and strain every joint in her.

The First Forced Landing.

Few pilots ever forget their first forced landing. The engine begins to splutter in mid-air, and finally subsides into silence. No spacious aerodrome, with staring windmarks, is handy. You gaze frenziedly round. You are just high enough to have a fair choice of fields from which to select. You are over agricultural land, not crossing the East End, mercifully. You are cute enough to know the breeze in your face is the slipstream of the propeller, and to notice by the blue trail of the chimneys beneath that the pukka natural wind is blowing in quite a different direction. You remember that corn and hay always cause a crash, and stare earthwards till you spot a field which is undeniably carpeted with short turf. You notice with a shudder that a brook along one edge of it apparently indicates a steepish slope, and hastily pick another field. You suddenly see this field is fringed by trees which may be tall, and select yet another field. You begin handling the controls jerkily in your anxiety not to overshoot the field: for as the engine has gone "dud," you cannot rise and make a second shot. At last you land, tremulously, rejoicing no instructor was watching, but in safety.

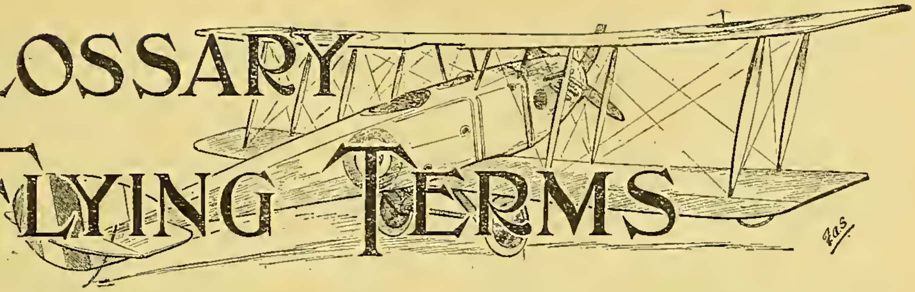
In France.

Then you are transferred to a scout squadron, and commence to learn landings all over again. At last you can make the tyres of a 130 m.p.h. scout kiss the turf like a shy lover: and you go out to France.

No. It is not a back garden. It is not an allotment. It is the aerodrome. It is *our* aerodrome. Yes, we land in it. Yes, you have to land in it. Do people ever ram that hedge and ditch? Rather.

You begin to wish you had gone in the infantry. Landing a scout on this lilliputian aerodrome reminds you of trying to drop a vegetable marrow into an egg-cup from 15,000ft. You go up. You "land"—at least, you call it a landing. The irate Squadron-commander has other words for it, which he recounts faithfully, whilst the mechanics pick the *débris* of what was once an aeroplane out of what was formerly a hedge. At last you, too, manage to land in it. You drop from highest heaven like a plummet. Just before you and your machine are about to be resolved into matchwood and mangled entrails, you cock the 'bus's snub nose impudently heavenward. Down comes her tail—with not too much of a bang, if you are lucky. Her tail skid bites deep, as the undercarriage flops to earth. The spread planes catch the head wind, and soak all the run out of her. She scurries forward a little, and stops short of that eloquent gap in the hedge. You least of anyone can understand why you are not well on the way on a much longer flight, but the fact remains you can't be because you burn your fingers as you light a cigarette with your last match. A fortnight later you think nothing of it, and join in roasting the latest arrival from England, who can't sleep at nights for thinking of that hedge.

A GLOSSARY OF FLYING TERMS



Our articles on "Flying Facts and Theories" have become so popular and have excited so much correspondence that we have decided, in the interests of those motor cyclists who are not very familiar with the names given to the various parts of an aeroplane and other terms used by the Air Services, to publish a glossary of these terms. The explanations, where it seems desirable, will be illustrated by drawings.

SPECT RATIO (SEE FIG. 1).

A designer finds that each wing of a
ntemplated machine must possess 120
uare feet of lifting surface. He can
range the required area either in the
rm of a long and narrow plane, say
ft. × 2ft., or of a short, broad plane,
y 30ft. × 4ft. The width of a plane
om end to end is called its "span,"
d the depth from front to back its
chord." The ratio between span and
ord is the "aspect ratio." In actual
actice an aspect ratio of about 5 or
to 1 is adopted. It is only the fore
rt of a plane which engages still air:
e air engaged by the rear portions of
e plane is disturbed, and consequently
ords less lift. At the same time it is
possible to obtain the desired curvature
the plane and the strength of structure
thout a chord of appreciable length.

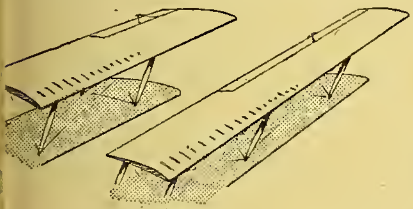


Fig. 1.

VION.

The official name for a military aero-
ane in the French Army.

NK.

To tilt an aeroplane sideways in making
turn. The necessity for banking will
cur to any motor cyclist who will
agine the result of trying to make a
arp turn on his machine while keeping
e machine vertical, especially if he
members that 45 m.p.h. is a low
inimum speed for aeroplanes and that
eeds of over 150 m.p.h. are attainable.
ntrifugal force will cause either a fast
otor cycle or a fast aeroplane to skid
twards from the centre of a sharp
rn. Fig. 2 shows an aeroplane flying
raight, turning on the flat, and banking
rrectly. The centre figure indicates
at as the machine skids sideways, its
anes skid sideways through the air, in
dition to being thrust forwards at the
r. In other words, they do not fully
gage the air in the manner for which
ey were designed; consequently they
not provoke a proper reaction or
tain full lift. In a very bad skid they
ay cease to get any lift at all. On the
her hand, if the machine is banked, as shown on the right, centrifugal force is still trying to fling the machine outwards from the centre of the turn: but the "flat" or underside of the planes is now opposed to the mass of air into which centrifugal force is trying to fling the machine, and a considerable resistance is thus set up.

To put the matter in another way, when an aeroplane is flying straight forward, the chief unfriendly force is gravity, which endeavours to pull it vertically downwards, as shown by the line A B in fig. 2. When the aeroplane turns to the right a second unfriendly force, namely, centrifugal force, tries to fling it in the direction of the line C D. The resultant of these two unfriendly forces acts along the line E F, and by "banking" the machine the full resistance of the planes is concentrated at right angles to the line E F.

BAROGRAPH.

An altimeter which records its readings, *e.g.*, with indelible ink on a paper roll. Such a record will automatically register the altitudes attained during the whole course of a flight. Sealed barographs are used in attempts to break the altitude record.

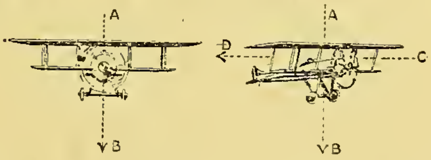

Fig. 2.

BAY.

The square enclosed by a couple of struts and the members to which they are attached. A bay is therefore, properly speaking, a square. The term is sometimes used loosely instead of the term "cubical bay" or "cell," which implies four struts, and the portions of plane or fuselage enclosed by them. The portion of a biplane wing shown in fig. 3 exemplifies the point. In strict accuracy, A B C D is a "bay," and the cube A B C D E F G H is a "cell" or a cubical bay, but the word "bay" is not infrequently applied to "cells," especially when used of the divisions of a fuselage. A B C D is the "outer bay," and C D J K is the "inner bay" of the wing.

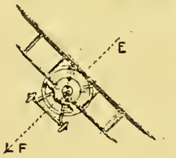
BIPLANE.

A heavier-than-air machine with two main lifting surfaces set one above the other.

Briefly speaking, as it is the front of the plane which gives the machine most of its lift, it pays to use a high aspect ratio. Great span compels the use of very heavy spars in the wings, so that where high aspect ratio is required it is better to distribute the span over two or three comparatively short wings, rather than to use one pair of very wide wings. On the other hand, the more planes we use the more struts and bracing wires we need, and the greater becomes the drift; also, the increased number of planes may interfere with the field of vision, and, in the case of a military machine, with the field of fire.

BOOM.

The chief fore and aft members of the "open" fuselage of a pusher machine; their full name is "tail booms." They are usually constructed of steel tubing, as opposed to the wooden longerons of a tractor fuselage, and they are widely spaced at their front ends to afford clearance for the propeller (see fig. 4).



BRACING.

The use of struts and wires to transfer stresses from point to point. Thus in fig. 5 the whole spread of the wing is provided in order to lift the fuselage F in the centre; and the "lift" is transferred from point to point along the wing by the strats S S S S and the flying wires W W W to the fuselage.

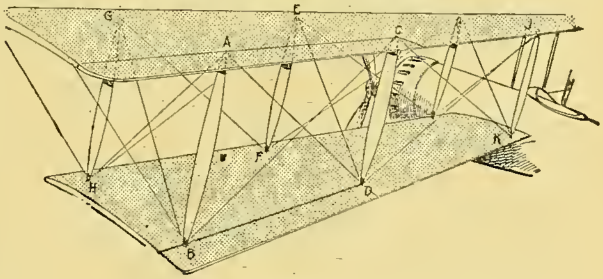


Fig. 3.

A Glossary of Flying Terms.—

CAMBER.

The curvature of a lifting or controlling surface.

CAVITATION.

From "cavity": the tendency of a propeller to carve out a hole in the air, as it actually would do if the air were not a fluid medium.

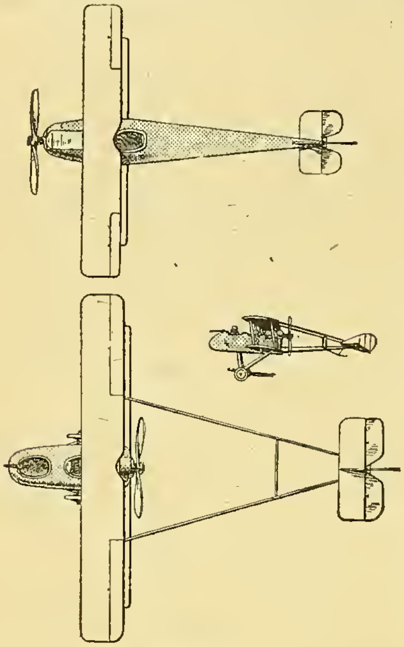

Fig. 4.

(Top) Tractor. The two lower drawings show the pusher type of aeroplane.

CENTRES.

Centre of Gravity.—The centre of weight: the point about which the aeroplane would balance if it were suspended.

Centre of Drift.—The centre of resistance. Applied to a single part or surface, it means the point at which the resistance of that part or surface acts or balances. When we speak of the centre of drift of a complex structure, such as an aeroplane, we are speaking of what is called a "resultant," *i.e.*, the various drifts caused by all the planes, struts, guns, passengers, etc., "result" in a total drift which centres at some discoverable point in the front elevation of the machine. In a similar way, of course, each part of the aeroplane has its own private centre of gravity, and the centre of gravity of the complete machine "results" from the total and disposition of the weights of the parts.

Centre of Pressure.—A line running from the outer edge of one wing to the outer edge of the other wing, on which the air pressure balances. The centre of pressure in a complete aeroplane is, of course, a "resultant" of the centres of pressure of the various surfaces, and may be an imaginary line at right angles to the fore and aft axis of the fuselage.

Note on the Various "Centres" as affecting Design.—Two of the above centres are practically stationary in any given machine. The centre of gravity can only vary if weight is dropped overboard or transferred from one part of the machine to another. For this reason bombs and fuel are carried as close to the centre of gravity as possible. If several 112 lb. bombs or an eighty gallon petrol tank were mounted on the tail or near the wing tip, the balance of the machine when loaded or unloaded would be ludicrous. The centre of drift is tolerably stationary, since the machine is designed to be symmetrical in a head- view. It is, however, possible for t centre of drift to shift when the machi is subjected to wind pressures striking at an angle: and advantage is taken this fact in various attempts to secu automatic stability.

The centre of pressure differs fro those of gravity and drift in bei extremely mobile. Consider, for exampl the position of the centre of pressure the sheet of notepaper shown in fig. (February 14th, page 156). As t centre is a line, not a point, in fig. it will be the front edge of the pap and in fig. 2b it will be a line dra across the paper half-way up. In fig. the centre of pressure (or "C.P.") w be nearer the top than the botto

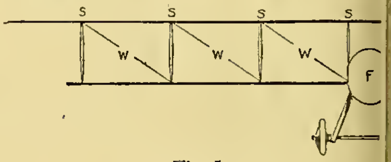

Fig. 5.

because the front edge of an inclin surface engages undisturbed air. Co paring these three sketches, it is cl that the C.P. moves backwards do the surface as the angle of incide increases. The mobility of the C. is utilised to obtain stability agai pitching, rolling, and yawing, as w be explained in the definitions "Stability."

CHORD.

In geometry, the straight line joini the tips of an arc: so, in aeronautics, straight line drawn from the leading front edge of a plane to the rear trailing edge.

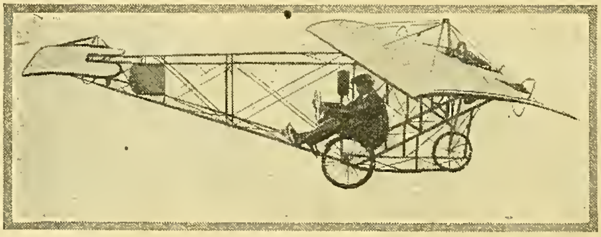
"Pleasure" Flying after the War.

A Motor Cycle-plane within the Reach of All who can Afford a Motor Bicycle.

WHEN the war is over it is prophesied that flying will become popular, and that the Air Service will claim for its own many of the young men who, before the war, were keen competition motor cyclists. There will be private aeroplanes also. Young motorists with means may prefer an aeroplane to a Rolls-Royce car, and motor cyclists probably will experiment on their own account to produce a machine for themselves. Some enterprising manufacturer may evolve a "Ford" type flying machine for the masses, and flying stations may be built near every large town. Conservatives of a past generation may shake their heads, but if one asks any of the younger generation—boy-men who are now war pilots—the reply is a vigorous affirmative.

At present aeroplane engineers are concentrating upon the development of the high-powered gigantic battleplanes and small and faster scouts. There may come a time, however, when the popular lightweight type of aeroplane will be considered seriously—as a small affair equipped with a motor cycle engine.

It must be remembered that some of the early flights were achieved with planes fitted with engines of quite low power, while A. V. Roe, one of the most persevering pioneers—an ex-motor cyclist, by the way—used a J.A.P. motor cycle engine.



A miniature monoplane, the working drawings for which are advertised in America for 8s. 6d.

In America an aeroplane designer is already appealing to the motor cyclist by extensively advertising working drawings, sold for about 8s. 6d., for maki a small monoplane which, it is claim develops a speed of 35 to 60 m.p.h. w an ordinary 7-9 h.p. motor cycle engi

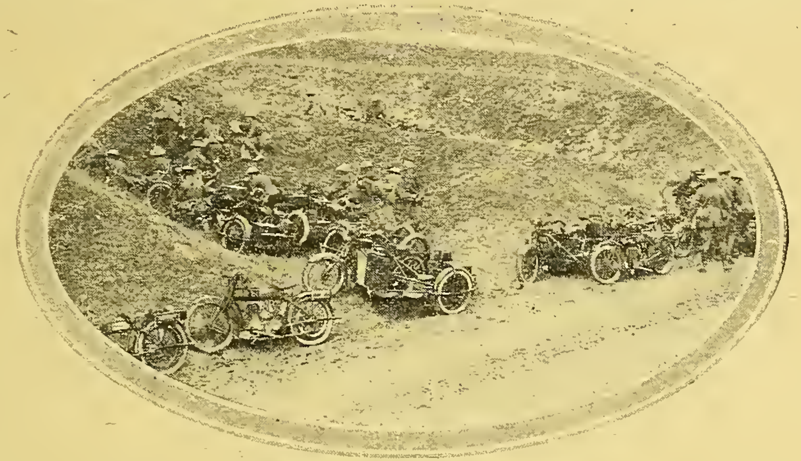
It is said that with these drawin and a shed, barn, basement, or ba yard large enough to assem the machine, it is possible construct this machine with other tools than a saw, hamm and a pair of pliers. The fra is of wood, and the wings be detached in a few minut The length of the fuselage 16ft. One of the American chanical journals states that t machine is "undoubtedly smallest successful monoplane the world," while another jo nal asserts that the inven "has solved the problem producing small machines a cheap price for universal service."

As will be seen from the illustrati the machine somewhat resembles gliders of ten years ago, and, if it only rise a few feet from the grou such a machine would no doubt aff a large amount of excitement.

THE REAL MOTOR CYCLING.

How the M.M.G.'s fought a Five Days' Rearguard Action. By "Gunner."

IT was in January, 1915, that the first battery of the Motor Machine Gun Service landed upon the shores of "sunny" France, and up to March 22nd last no Service had been more misjudged. No one ever suggested that it was inefficient in any way, but, after various attempts by G.H.Q. to use what they knew was a valuable fighting force, many people in military circles had come to regard the Motor Section of the Machine Gun Corps as a "wash-out." That is as far as they were intended to be used, viz., as a mobile force. At Neuve Chapelle, Hill 60, Loos, and Cambrai, the M.M.G.'s were in action, but the Vickers-Clyno combinations always got so far, and then difficulties arose and guns had to be dismounted.



Motor machine guns in a sunken road in France.

The withdrawal from Cambrai to Albert gave the Service its chance, and, to the credit of those responsible, they utilised it to the fullest extent. From the moment the decision to retire had been made, until Albert was reached, the M.M.G.'s were always in the front—or should it be the rear when a rearguard action is being fought?

Checking the Germans.

I cannot give details of the experiences of all the batteries concerned in checking "Jerry's" headlong rush, but some incidents from the diary of one of them may interest our readers. They will prove that the Army's confidence in the usefulness of the motor cycle in modern warfare has not been misplaced.

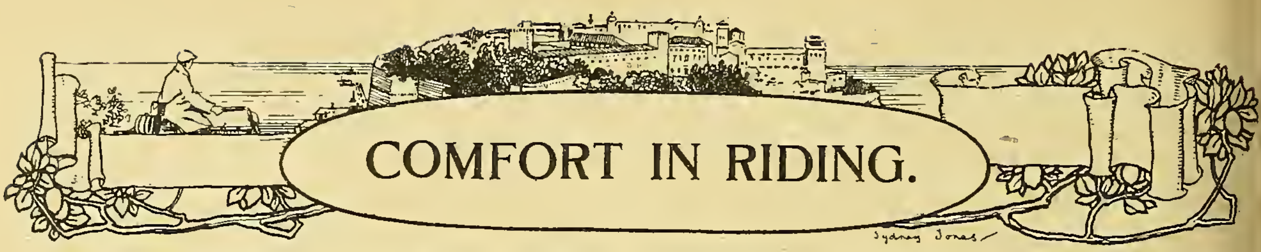
At two o'clock one morning we were coolly informed that we were to proceed to —— Road, that the only troops of our own in front of us were a few stragglers, and that the Germans were to be held there. The battery scout on reaching the spot challenged some moving forms in front, and instead of hearing the familiar English he heard the "zip" of a bullet by his ear. Engines were shut off with some haste, and guns rushed off the bicycles into position. Shots were exchanged in the dark, more for moral effect than actual destruction, and daylight found both guns and bicycles neatly "camouflaged." The next development was on the flanks, and "out of action" was given just in time to save our skins and, incidentally, our guns. This occurred on two more occasions that same day, and each time the bicycle responded nobly.

The most exciting moment of the lot came the following morning, the 23rd. All our guns were mounted on a ridge, with the Clyno combinations hidden on the road at the back of it. Dawn revealed the fact that the infantry in front of us were gradually withdrawing. Nearer came the Boche, and those who were not actually on the guns anxiously examined carburetters, felt tyres, cleaned plugs, and everything to ensure that the first kick on the kick starter should set the engine throbbing. As Fritz came over we gave him his leaden rations until the boys in front had got clear. Again our danger came from the flanks—a fact which was brought to our notice by a machine gun enfilading us from the right. When this danger was increased by a daring Boche sniper, our C.O. deemed it expedient to give the enemy our place in preference to our company. "Out of Action" sounded. By the time the guns and ammunition were on the bicycles, all the engines were throbbing except one. Bullets were "phizzing" to some tune, and clutches soon got busy. Luckily, we had a descent in front of us, and the driver whose "'bus" was stuck was saved by shoving the Clyno along in second gear when it started. Halfway down the hill one of the passengers received a piece of shell in the head. Jamming on his brakes, the driver pulled up, and lifted the dead man off. The machines succeeding him did some exhilarating swerves, but presence of mind saved the situation. Several machines were "winged," but nothing serious happened to hinder the progress of the battery, which took up new positions further in the rear to await another exciting chase.

Saving the Loaves.

A very amusing incident happened in the next stunt. It was a case of neck or nothing again, and as the bicycles were flying along a bend in the road revealed a ration dump left behind by our people. Despite the fact that Jerry was on top of our heels, every machine pulled up. Loaves and milk were thrown into the sidecars. Drivers had only time to slip the gears into neutral before they were in first again.

The whole five days were occupied by such incidents. Machine guns travelled hundreds of miles by the aid of the motor cycle. The Germans by now must have a distinct regard for weapons so mobile. Our own infantry in the past have been slightly amused to see the "motor" machine guns beside them, but when trenches vanish and open warfare prevails the full significance of the word "motor" is revealed.



COMFORT IN RIDING.

Is the Comfort of the Rider primarily dependent on the Position due to the Construction of the Machine or to that of the Saddle?

IT is all very well for "Chinook" and kindred souls to write about "Riding Position" and adjustable handle-bars, twiddly footboards and wonderful saddle-pillars that will slide up and down at a wink from the owner, so that when he comes to sell his ten-year-old mount it will just fit any prospective purchaser. But I am going to be original and unconventional, and claim that real riding comfort is not to be obtained mainly through any of these suggested remedies for present defects in the physical well-being of the owner of an average-sized machine.

Instead of worrying over the height of the saddle above the ground or above the footboards, and the space allowed for the rider's legs or the angle at which his arms are compelled to do their all-important work, why does not someone call attention to the saddle itself? I am sure that what one sits on is really of far more importance as regards one's comfort than is the position one is forced to take up—provided, of course, that this latter is not allowed to reach absurd lengths of discomfort. We can all sit on a straight-backed chair with a soft cushion underneath us for far longer periods of time than we can comfortably endure an elegant lounge on a hard wooden settle.

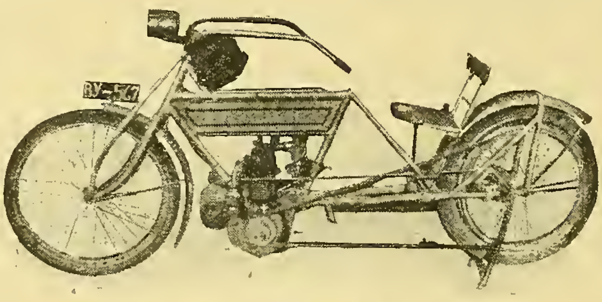


Fig. 3.—An early experiment in seat construction.

And is there any hardened rider who will seriously maintain that the hard-bottomed chair is not far and away superior to the present arrangement called a cycle saddle? Some manufacturers certainly have made efforts to free us from this bondage, but they have not met with unqualified success. The T.M.C. sidecar combination included this in its many other excellent features of originality, and incorporated a bucket seat that always looked very comfortable, though I cannot speak from experience as to its efficacy.

The XL'All Saddle.

As regards the efforts of the saddle makers themselves, the XL'All made a bold stroke in introducing their pan seat saddle. They soon modified their design, however, and secured more success with the modification than they did with the original, and so some people will certainly say that the average motor cyclist thus proved his satisfaction with the present form of saddle, and the absence of any desire on his part for an innovation to increase his already ample comfort. But not at all; the new saddle was an innovation, and, like all other novelties, cost more money than the commoner article. Which explains everything.

And, strange to say, the XL'All pan seat was not always an improvement as far as the rider's comfort was concerned. On one combination that I owned it was bliss, on another it was misery. And here the "size croakers" will have a chance to score, for everything in the case of this particular saddle depended on the size of the rider and the relative positions of footrests and saddle on the machine. On the first machine the footrests were higher than normal.

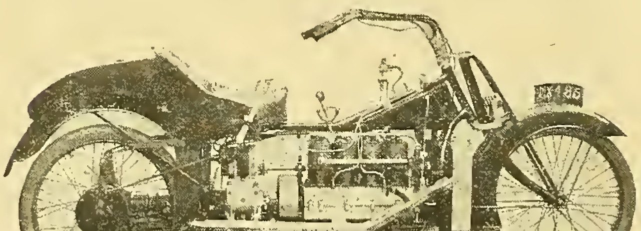

Fig. 1.—The T.M.C. or Ogden motor cycle. This premature machine contained, among its many excellent novel features, a seat on the basis advocated in the accompanying article.

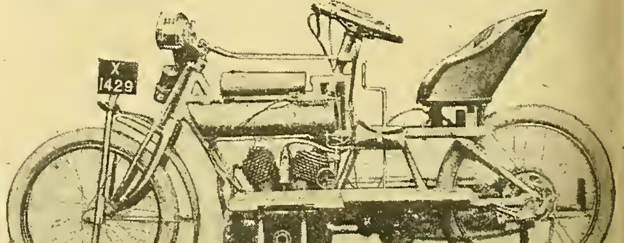

Fig. 2.—Another early example, incorporating also wheel steering. In many respects this machine is reminiscent of the old tricar, and, indeed, is possibly a converted example.

iding Position.—

n the other the footrests were relatively low, and so e rider's legs were normally more or less vertical. ush cycle practice demands a saddle that will enable the rider to get his legs as close together and as vertical as is reasonably possible, so that he may pedal the machine along—and in early motor cycles there was doubtless every justification for the continuation of this practice.

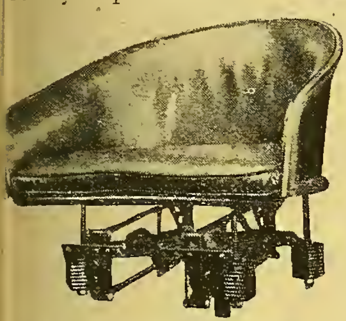

Fig. 4.—An example, on the market in 1905, of the bucket type of seat. This seat, having no peak, would probably afford little extra comfort unless it were tilted backwards at a considerable angle, and other considerations might prevent this from being done.

But the modern motor cycle does not need pedalling, and because of this there is no need for the machine to be designed so that the rider's legs will be aturally vertical and a push cycle type of saddle ecessitated in consequence. Therefore, if the achine be designed with this point kept in mind there no necessity for its saddle to be on the narrow ertical leg position push cycle lines. And the L'All saddle is not on these lines—it rather compels e rider to adopt a sitting posture. All which is as should be *if the motor cycle is correctly designed.*

The Importance of Frame Design.

My plea thus resolves itself into one for motor ycles that will provide a atural sitting position for the der, and, as a result, will in-olve the provision of a saddle at will be a saddle in nothing ut name. It will really be hat every saddle pretends to be—a seat. I would like to efer to the T.M.C. motor ycle again as an example that as actually materialised incor-orating these ideals, but to ake an exhaustive reference this machine takes up so uch paper—one never knows nder which of its many names is most likely to be recog-ised, and the full list is really oo formidable.

But most intelligent readers ill have gathered the gist of y argument, I think. We want a machine with some orm of bucket seat—preferably one that may be added or upholstered for post-war roads—and so rranged that the rider *is normally sitting and not half tanding on it.* As a result of the comparatively level floor of the seat the footboards must be higher than usual, or the rider's legs will dangle. This relative raising of the footboards may be accomplished in one of two ways—either by simply raising them or by lowering still further the saddle pin. Of course, the provision of a bucket seat will militate somewhat against the simplicity of the running mount, but who makes a running mount nowadays?

A compromise may be attained for small solo machines in the shape of an anatomical seat, but it should be seen that some provision is made for the outlet of water when the machine has to be left standing in the rain—*experto crede.* With the present-day lightweight, really efficient saddle arrangements are nothing more nor less than impossible. The main point that makes all the difference between an ordinary saddle and a special one is the presence or absence of support for the back as distinct from that portion of one's anatomy that takes the dead weight, and as this provision would militate somewhat against other and perhaps more vital considerations in the case of the small solo machine, it will have to be ruled out of court.

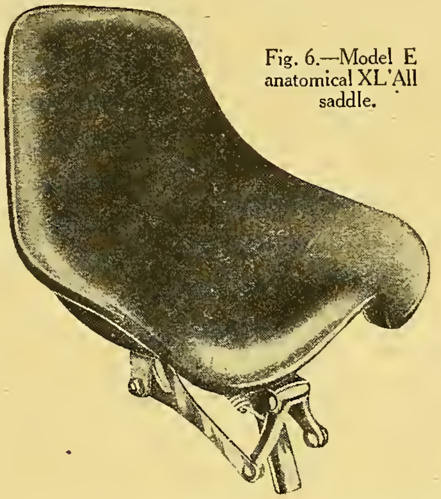

Fig. 6.—Model E anatomical XL'All saddle.

Nevertheless, an attempt in this direction has been made. The saddle, or seat, was simply a cushion—it could quite well be an air cushion—and there was a rest for the back of the quickly raisable or lowerable type. Something after this style would be the limit for riders who regard the running mount with affection, but otherwise some such arrangement as that shown in the sketch should be more satisfactory.

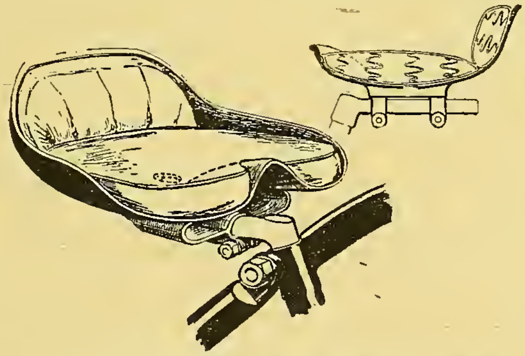

Fig. 5.—The saddle suggested by "Rama." Note the hole to allow the egress of water when the machine is left out in the rain (the upholstered cushions, being loose, would be removed, of course). This sketch simply illustrates the shape of the seat itself, and does not attempt to cover the question of the springing of the saddle as a whole.

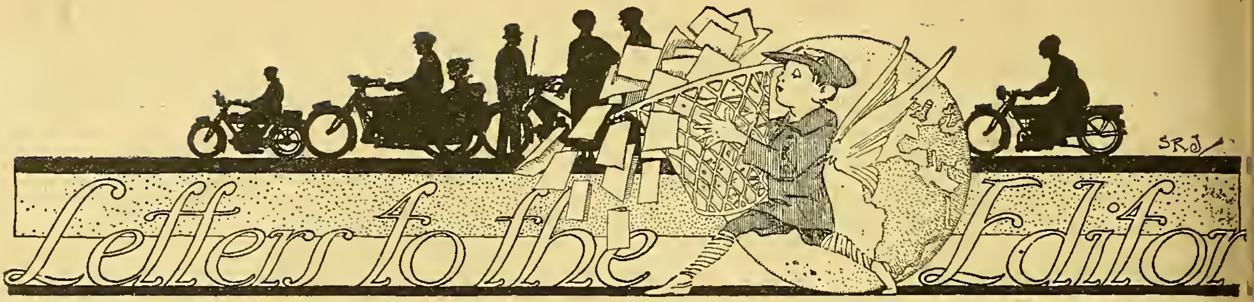
The construction of the framework of this suggested saddle is much like that of the XL'All Model E—known as the "Sidecar Seat and Rest," although when I first thought of it I had never seen this model, all my experience having been with the smaller pan-seat type. The framework is one piece of pressed steel and is covered on the inside with leather. On top of this are placed two cushions that ensure some extra degree of comfort for the rider on a long run. Thus the rider can arrange them within limits to meet his own fancies. RAMA.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

THE HORIZONTAL COUPLE.

Sir,—Please let me hasten to dissuade "Bob-weight" from any suspicion that I have discovered a new theory of balancing. At the same time, I must admit that his criticism is in part justifiable.

The article in question was written to explain certain previous matter in a simple manner for the benefit of non-technical readers, and possibly errs in the elimination of too much detail.

Perhaps "Bob-weight" will raise no objection, therefore, if his remarks are gratefully accepted as an expansion of those details which were not sufficiently explained in the first instance. WHARFEDALE.

A BAFFLING EXPERIENCE.

Sir,—With reference to a letter in *The Motor Cycle* of April 18th by Mr. F. W. Chapman, it may interest this gentleman to know that I had a somewhat similar experience on my Triumph about a year ago.

The engine, which had been running well, suddenly started misfiring, and I, too, did the same as Mr. Chapman. The plug sparked quite well when taken out, but nothing happened when it was in position. Suddenly I saw the trouble. The high-tension wire was shorting with the carburetter controls, just underneath the tank. The two were only just touching, and when the plug was removed the wires were at the same time separated, and the spark was O.K.

Perhaps Mr. Chapman has the same trouble, and if not I hope I have given him a clue on which to work.

Canterbury. A.G.C.

Sir,—The misfiring (as reported in your issue for April 18th) which Mr. F. W. Chapman experienced was probably caused by the swelling of the fibre brush on the magneto contact breaker rocking arm. He had probably been driving through heavy rain, which caused the fibre brush to swell and stick intermittently with the platinum points apart. During the night the brush dried out, and consequently worked freely again.

THE LODGE SPARKING PLUG CO., LTD.

TALL STORIES.

Sir,—I have heard some pretty tall stories before now about motor cycling by aspiring young speed merchants, but this, the latest, I think, absolutely takes the bun.

The other day a fellow cadet tried to make me swallow the following yarn: "I own a $2\frac{1}{4}$ h.p. Diamond two-stroke, and recently rode from Essex to the North of Scotland in two days.

"The fuel used on this journey was acetylene gas supplied by an ordinary lamp generator, which had to be recharged every twenty miles or so.

"While travelling at speed the sparking plug blew out and hit the tank. Luckily this occurred just outside a garage, and so I went in and was supplied with a new cylinder, and was under way again in about half an hour."

On being asked about the arrangements made for supplying gas to the engine, he replied that a pipe was simply taken from the generator to a point in the induction pipe between the carburetter and cylinder, the control being by the ordinary carburetter throttle! CADET, R.N.

Dartmouth.

THE A.A. AND THE UNITED COUNCIL.

Sir,—The following reply has been sent by the Aut mobile Association to the proposals recently conveyed b the secretary of the United Council of Motor Users, Pr ducers, and Distributers, that the clause in the Council constitution, upon which the Association's refusal to joi the Council was chiefly based, be amended; and that conference be arranged to discuss amendments.

STENSON COOKE.

April 17th, 1918.

Dear Sir,—Your letter of the 15th March has no been considered by my committee, and I am directe to inform you that in their opinion there is at preser no reason for any conference on the lines suggested.

I am again to refer you to our letter of the 1s November last, expressing my committee's opinion tha questions on matters pertaining to the production, di tribution, and use of motor vehicles, which may b affected by legislative or other proposals, can best b dealt with at conferences of the bodies concerned, t be held from time to time as the occasion may aris

Yours faithfully,

STENSON COOKE, Secretary,

The Automobile Association and Motor Union.

Horace Wyatt, Esq.,
The United Council of Motor Users,
Producers, and Distributers,
39, St. James's Street, S.W.1.

TO MANUFACTURERS.

Sir,—As a constant reader of *The Motor Cycle* for man years, I should like to write you on two points connecte with the motor cycle industry that appear to me of re importance.

First, tanks. The old pattern narrow tank, to hold gallon or less of petrol, always gave trouble sooner or late but usually took two years or so to do it. The modern wid tank, holding over two gallons, takes about two months t start its first leak, and gives trouble at periodical interva ever after. Seeing that motor cycles are so largely used fo business purposes nowadays, this is a very serious matte One cannot help thinking that the mistake made by tan manufacturers is that they employ tinsmiths when the should employ boilermakers. For goodness' sake let us i future have a good honest row of rivets on our tanks, or l them be made of steel sheeting oxy-acetylene welded.

Secondly, carburetters. *(a)* When will manufacture realise that a really petrol tight cover to the float chamb is an absolute necessity if there is to be any real economy i petrol? *(b)* Some carburetter manufacturers do not yet see to have realised that, in the inverted needle type of flo chamber, it is absolutely essential that the action of the flo should be restricted to very narrow limits by a support und the float. No one would dream of allowing the ball of non-return valve in an oil pipe a run of half an inch or mo backwards and forwards, and yet I know of one carburette at any rate, sent out to this country (South Africa) with r tubular support under the float, with the result that the flo is bobbing up and down with half an inch or more of petr under it. It is easy to imagine the wild devil's dance do by the float on rough ground, or when travelling at spee This instrument is the multi-jet type and costs £4 out he as a special fitment. E. A. D. SOUTHBY.

Johannesburg.

A LUBRICATING TIP.

Sir,—Referring to the letter by "Dan" in 7th ult. issue. As he appears to have had some experience with castor oil, would he be good enough to state whether castor is better than engine oil as a lubricant, irrespective of cost, as his letter appears to give that impression, and also the effect on formation of carbon in comparison with engine oil?

WIMBLEDON.

A USEFUL TIP.

Sir,—I give the following tip, which you may think worth publication. When standing still on a solo machine, with the engine running free, if the engine is running very slowly and tends to stop, slightly tilt the machine between the legs, so that the float chamber is brought to a higher level in the jet. The result will be that the engine will accelerate slightly. This, of course, only applies to machines where the float chamber is to one side of the jet.

I find this tip very useful when stopping to light a pipe, when one's hands are not free to open the throttle slightly.

E.E.F. S. E. FOX.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—With reference to the letter of "Sufferer" (Farnborough), I would very much like to endorse his views, being one of the persons in the same position.

It does not seem at all fair that motor cyclists, who on joining up had to prove that they had had previous experience, should have to take a place lower than M.T. drivers. On the whole, a motor cyclist requires an equal, if not a greater, amount of practical and technical knowledge than a car driver.

I think you will be doing motor cyclists of the Royal Air Force a very great service if you take up this matter on their behalf.

UN AUTRE.

Wye, Kent.

Sir,—I have had two years with the balloons in France, and have noticed the lack of appreciation shown us, as also has nearly every other R.F.C. D.R. to whom I have spoken. I consider we have every right to be classed as "technical," and that a great injustice is being done to us. I feel sure that the influence of *The Motor Cycle* would greatly help to right this wrong. I hope to see many other letters on the subject appearing in following issues. Why, as "Old Reader" suggests, can we not be classified as D.R.'s? Surely we are as much entitled to the title as the R.E.

1st A.M.

Birmingham.

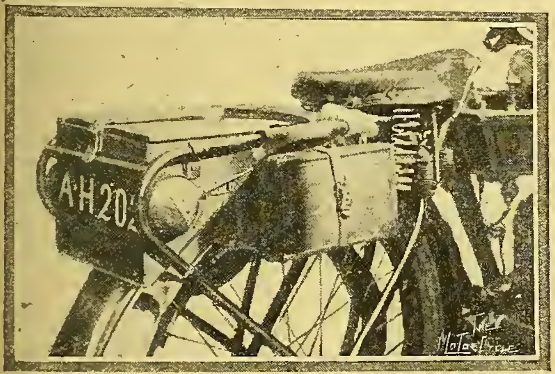
[We deal with this subject editorially.—Ed.]

AN IMPROVED TOOLBOX.

Sir,—I noticed in *The Motor Cycle* of March 21st an illustration of what I think was called an "improved toolbox," which was described as being "registered." It does not seem to me to differ essentially from one which I made myself two or three years ago, and have used ever since. I enclose photograph showing its arrangement.

AH 202.

Diss.



A toolbox constructed by the writer of the accompanying letter.

FRONT MUDGUARDS.

Sir,—Some time ago I noticed a description of front mudguards, giving the different styles used.

One was a description I took to refer to the P. and M., and was described as bad for clogging up with mud.

I had a P. and M. for three years and never had any trouble (mud or any other) with the machine, and would not have parted with it if it had had the power required, but I have done fifty miles in one day with four up.

I cannot speak too highly of this machine. Now I have a machine with the perfect (?) front mudguard, and it has caused me more trouble in three months, and is not right yet and never will be.

One mistake is, I think, that the guard is fastened on to the unsprung part of the fork. A second fault is that the spring-up front stand is the only fastener for the bottom part, and is quite inadequate to stand the vibration on a 6 h.p. Moreover, the Druid fork does not fit in with this sort of shield. And when it comes to dismantling, fancy twenty-six odd small bolts and nuts, and rusty at that.

Besides it is one of the dirtiest I have met; both legs mud to the knee, the inside (next cycle) mud from end to end, and the glass screen covered, and this at under 20 m.p.h.

Kirkwall. ORKNEY.

A GOOD AMERICAN.

Sir,—May I, as an interested reader, add my opinion to the controversy on English *v.* American machines, which I have followed?

My brother has an "over-engined crudity" combination, fitted with 760×90 mm. tyres, which I have driven many hundred miles, and found it the acme of comfort and easy handling, possessing also speed and reliability. As for reliability, this machine, after having covered 7,000 miles, carried my brother and me last August a tour of 970 miles, which was done in five days' actual riding.

Starting from North Notts, we rode into Exeter, and from there toured Devon, the outward journey being 225 miles and the return journey 249 miles.

On these two occasions we carried luggage, spares (not needed), three tins of petrol, one gallon of oil, with passenger—weight over 20 stone. This is a good test for the engine, which ran continuously, except for replenishing the tanks.

But the way the bicycle passed several English combinations, not to mention three solo machines of well-known makes in open contest, was sufficient proof of efficiency, and was not the least enjoyable part of the tour.

MILDRED SMITH.

PETROL FOR MUNITION WORKERS.

Sir,—Some few weeks since your contributor "Ixion" published a paragraph which aroused some indignation in France, and which, I think, calls for comment.

The paragraph in question was in connection with the new petrol restrictions, and he was attempting to make a case for the munition worker. His opinion was that the munition worker, before all others, should have petrol for purposes of recreation. Now why on earth should he? He has a safe job at home. He makes more money than he ever did in peace times. If he does work overtime he is generally paid well for doing it. He suffers no undue hardships and, when he feels tired, he goes on strike—while his countrymen are dying in different parts of the world.

Perhaps the most absurd contention made was that the man on active service at the Front was more healthy than the munition worker, had, in fact, a more healthy job. If that is the case then the man who has been on munitions for a couple of years must be in a fairly bad way. Take the infantry soldier. Supposing that he has not been killed by the "healthy" life he leads, does "Ixion" seriously think that it improves a man to live waist deep in mud and water? My own experience is chiefly with D.R.'s, and, without exaggeration, I can say that 80% of the D.R.'s who have done two years' riding in France suffer from rheumatism and, more or less, chest troubles, not to mention nerve troubles, etc. These things may not be serious now, but will undoubtedly be felt in years to come.

I think that most people will agree with me that if anyone should have petrol it should be the man home on leave.

France. D.R., R.E.

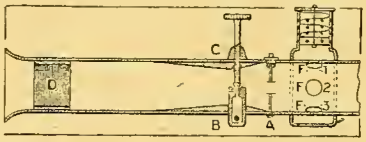
Sir,—Possibly the following may interest you. I am an enthusiastic motor cyclist, and an electrician in charge of the works plant of a Government controlled establishment here. Not being allowed to use my motor cycle to get home at the week-ends, I have to do the journey partly by train and partly by push cycle. The only train which suits me leaves here at two o'clock. On making application for my usual ticket on a recent Saturday, I was told that all tickets were sold for this train. Now the point is this: Ninety-nine per cent. of those passengers were on pleasure bent, their object being a league football match, while I and others, wishing to get to our respective homes, had to stand aside. This meant that I did not get home. Now, if the Government make it illegal for us to use our motor cycles to get home, why cannot they introduce some legislation on the railway whereby, in a case of this kind, ordinary passengers shall have preference of tickets and football supporters the available residue. If it is illegal to travel in the one case, it ought to be illegal in the other, as nowadays the trains are every bit as scarce as petrol.

Kilmarnock. DISGUSTED.

[It is often misleading to generalise without restraint from one's own experiences.—Ed.]

SIMPLE TYPE CARBURETTERS.

Sir,—Seeing that there had been some correspondence in your columns on the subject of carburetters, I thought that details of a home-made instrument might interest your readers.



The simply designed carburetter referred to in accompanying letter.

The carburetter in question was tried on a B.R.S. Norton with excellent results: it gave 118.5 m.p.g., 76 m.p.h., and terrific acceleration. As will be seen from the drawing, it consists of a straight metal tube fitted at A with an iris diaphragm operated by a Bowden wire. Just in front of this is situated the jet, the opening of which is controlled by a needle valve having a large knurled head, so that it can easily be altered from the saddle, there being a thread in the metal cap C. At D there is a piece of lamp wick glued inside the air inlet, which absorbs any blow-back, and so greatly improves the petrol consumption. The extra air inlet consists of a metal cylinder surrounding the inlet pipe, with which it communicates by means of holes F_1, F_2, F_3. Into this metal cylinder is inserted a barrel having holes in it, the opening of which is controlled by the usual type of throttle piston.

The carburetter was tried both with and without a float chamber, and no difference to the running could be noticed, except that the jet had to be kept further closed when no float chamber was used.

The carburetter was not originally intended to be particularly economical, but chiefly for obtaining speed; however, it was considerably less wasteful in fuel than that originally fitted. J.C.G.

Crowthorne.

CARBURETTER ADJUSTMENT.

Sir,—I have noticed recently that several correspondents have had trouble in setting Binks carburetters, and as I have used different types of these on several machines, perhaps my experiences may be of some use. So far I have never failed to get perfect results, and the only other carburetter I really care for is the Schebler, which also takes a lot of setting in the first place.

Though anyone can get very fair results from the three-jet Binks, I certainly recommend the average novice to stick to such straightforward instruments as are usually fitted as standard to new machines. To get really perfect results requires some experience, and no little patience.

To deal with the actual setting, I have always found singles to require larger jets than twins. A good combination to start with is as follows: Single, 500 c.c., pilot 00, middle 4, and main 8. Twins, 500-1,000 c.c., pilot 000, middle 3, and main 6.

Remove the carburetter from the stump, and, keeping the control wires in the position they normally occupy on the machine, mark the controls for fully open pilot and fully ope middle. It is no use trying to get these positions throug the air intake, as the choke tubes are not cylindrical.

Take the machine on the road, and, when the engine thoroughly warm, try running with the pilot jet fully ope First restrict the main air intake, and then try opening th extra air slightly. If no *maintained* increase in speed noticeable the jet is right. If the engine will take air, f a smaller jet and *vice-versa*.

Having got the pilot right, repeat the process on th middle jet. It is no use bothering with the middle jet unt the pilot is right, and no use bothering with the main unt the middle is right, as, when running on the middle je the pilot is also supplying petrol, and when the main open all three are working.

Having set the first two jets, lock the bottom air slid one-third open, and fit a main jet which gives a corre mixture at seven-eighths open throttle on the level, th extra air being closed.

The three correct jets are then in the carburetter, but may be found that the mixture is not right for all thrott positions. As turned out by the makers the mixture generally far too rich when the pilot is almost closed for tick over in free position, and rather weak when the middl jet is just opening.

To correct the first, file out the pilot jet choke tube o the air intake side towards the top of the carburetter. Th amount of gas passing to the engine is controlled by the are of the pilot choke open to the induction pipe, and the qualit of the mixture by the area of the pilot choke open to th air intake. Thus, filing as above gives a weaker mixtu when the pilot choke is almost closed, while not affecting th mixture when the pilot choke is fully open to the inductio pipe, the mixture then being governed by the area immed ately over the jet, which, of course, is not altered.

If the mixture is also found to be rich with the pilot abo half open, the filing should be extended sideways also.

To correct for weak mixture when the middle jet begin to open, fill up the already chamfered edge of the middl jet choke tube, and then file as required just as with th pilot jet. By proceeding on these lines it is possible to ge perfect acceleration on the two smaller jets.

To set the main jet the bottom air slide is used. A littl thought on the principles of the carburetter will show tha these air holes only affect the running when the main je just opens and immediately after. When running on eithe the pilot or middle jets, or with the throttle wide open, the have no effect at all.

Thus, if the mixture is found to be too strong when th main jet is first opened, as is probable, open the air slid further, until the mixture is perfect all the way up to seve eighths throttle. After that it should become weak.

Of course, there must be absolutely no air leaks anywher If the setting is correct with a warm engine it will give weak mixture when the engine is first started, so it is n advisable to slam the throttle wide with a stone cold engin Also a hill should not be climbed slowly with the thrott wide; about two-thirds to threequarters open is the righ slogging position.

For speed on the level, open to seven-eighths and no mor and if your machine slows a bit on a hill *close* the thrott instead of opening it. The engine will then pull with a Bink as with no other carburetter made. Then, if you come to bit of down grade, you can get a prodigious speed by openi up gradually until the throttle is wide.

To quote a few specific instances. Fitting a Binks to 3½ h.p. Sunbeam enormously improved the acceleration wit out affecting the maximum power, and gave positively u canny starting and slow running. Another Binks convert a 90 bore T.T. Zenith into a delightfully controllable machin with wonderful consumption, and no lack of power. Y another rendered the short but merry life of a certain raci flat twin much more comfortable for its owner. A fourt fitted to a Powerplus Indian, is filling me with fresh gratitud In fact, I have never known a properly set Binks do an thing but improve a machine out of all recognition. As rule, the better the engine the more noticeable the in provement.

In conclusion, the Binks is well worth while for anyo who will take some trouble with it. But if you do not kno or do not care, stick to two levers and one jet.

Ayr. BINKER.

THE LION MAGNETO.

The Latest Development of an Interesting Lightweight Magneto.

THE Lion magneto is not a new production. It is no new venture in an experimental stage, but is several years old—in fact, the first magneto was made previous to the war in 1914, and we described it, as fitted to all Radco machines, in our issue of February 17th, 1916.

The makers, the Britannic Electrical Co., Ltd., wish to correct the impression that it has just "arrived," and to give the motor cycling public to understand that it is a well-tried instrument and has behind it many years' experience.

We spent an interesting hour or so at its country home at Warstock, near Birmingham, recently. A small but well-equipped factory is as busy as most other similar houses. The whole instrument, except he Hoffmann ball bearings, is made here; magnets are cut, bent, ground, and magnetised. End and base plates are die ast in aluminium alloy; armature and contact breaker parts are cast in brass. Also the armature is wound, and a most interesting series of operations culminates in a six hours' running test.

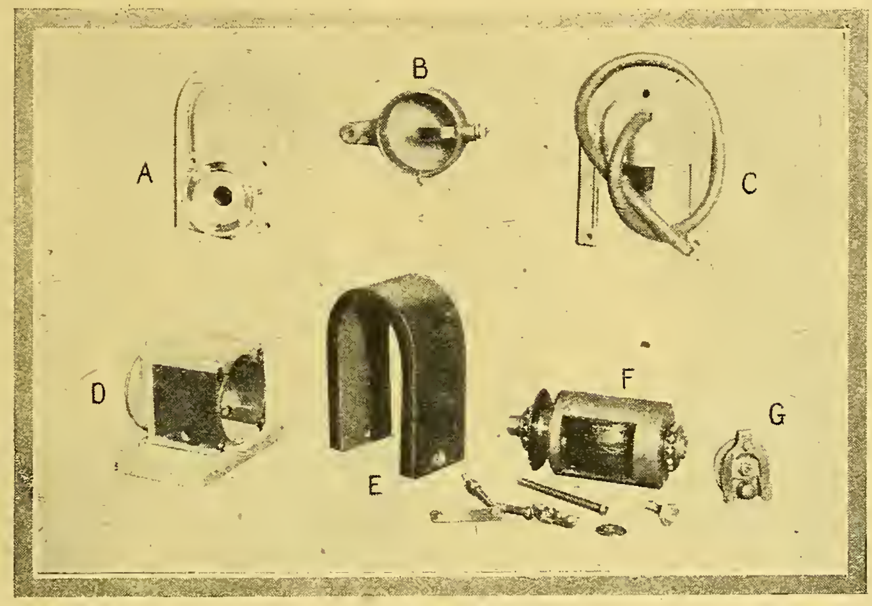
The general design is not unusual, and is substantially the same as that of the original model, the chief development being in the perfecting of methods of manufacture and test.

The contact breaker is somewhat novel. The operating cam is on the front face instead of on the interior face of the contact breaker body, thus giving the platinum points a horizontal breaking action.

Various stages in manufacture reveal a number of ingenious devices for the checking of faults in construction, notably in the armature winding processes. Three windings are separately tested on an instrument which indicates whether the correct amount of wire has been wound and whether any shorts are present. Another process extracts all moisture from the finished armature, and it is remarkable that so much moisture can lie hidden in an article composed of apparently dry metal, oil paper, and varnish. The testing of mica for the condensers and the method of check on the operator when assembling the condenser sheets are most interesting. In connection with the sheet mica test a Lion magneto has been in daily use for the last year or two without attention; this particular machine was the original model made by hand previous to 1914.

Although the Lion magneto is one of the smallest on the market, and intended only for lightweights, it has withstood much heavier tests; a Northern firm is using it on an outfit of approximately 5 h.p. The works manager, Mr. Alston, who has invented and made various instruments for checking and testing, tells us that he is about to run a magneto to destruction on a 10 h.p. two-cylinder light car.

A number of motor cycle firms have given the Lion exhaustive tests. As might be expected, the factory at present is handicapped by shortage of labour and material, but the output under normal conditions will be approximately 150 magnetos per week.



The Lion magneto dismantled.

A. End plate, carrying contact breaker bearing and actuating cam
B. Contact breaker strap and timing lever
C. End plate with high-tension cable attachment
D. Body and base plate
E. The magnet
F. Armature complete with slip ring and two ball bearings
G. Contact breaker

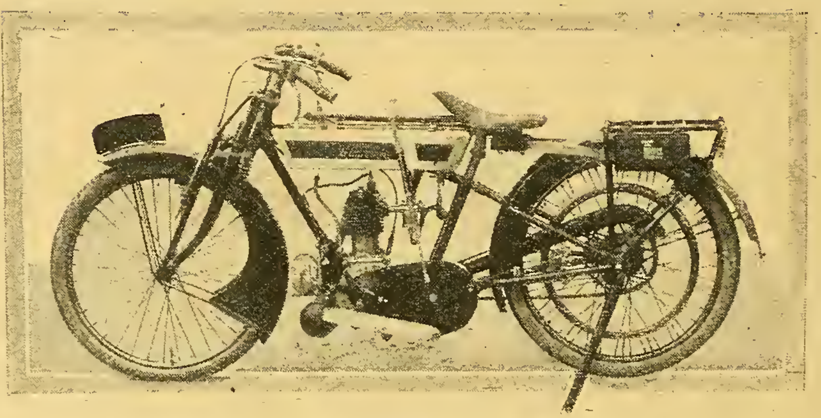
A MUCH REQUIRED BOOK ON TRANSMISSION GEARS.

JUDGING by the number of queries that we are continually receiving on questions connected with transmission, there is certainly plenty of scope for a reliable book on the subject, and Mr. Edward Butler, M.I.M.E., has recently attempted to satisfy this need in a book published by Charles Griffin and Co., Ltd., at 8s. 6d. net. The object of the book is to treat in a more exhaustive manner than has yet been attempted such matters as friction clutches, change-speed gears, and reversing methods. The author considers, and doubtless with ample reason, that there is much scope for further investigation into the whole subject, and this book should serve as a very useful groundwork for any designer who feels inclined to carry on researches into this all-important sphere. While the book is primarily written from the motor car point of view, and also deals with such distantly removed vehicles as tramcars, locomotives, and boats, the motor cyclist will find in it much to interest him. The book is plentifully illustrated.

The Edmund Spring Frame Motor Cycle.

2½ h.p. J.A.P. Engine, 70 mm. × 76 mm., 292 c.c.

IN *The Motor Cycle* of January 25th last year a reader, Mr. Percy Roberts, gave an interesting account of his experiences with an Edmund spring frame lightweight. One or two of his criticisms have been incorporated in the latest model Edmund. He suggested that the back mudguard should be better balanced, and that the back brake should be controlled from the footboard through a Bowden cable.



The 2½ h.p. J.A.P.-engined Edmund spring frame motor cycle.

The latest mo of this motor cy includes a brake fit up in the mam suggested by Roberts, redesig mudguards and spr footboards, while engine is the lat type J.A.P.

Messrs. Charles mund and Co., Lt Crane Bank, Chest whose spring fra has been so long the market, and been so well spol of by users, are a to supply a limi number of the latest models.

* * *

The National Motor Cyclists' Fuel Union.

The Point of View of the Union put forward by the Chairman.

MR. A. W. TORKINGTON, replying to our remarks regarding the meeting of the N.M.C.F.U. recently held in Coventry, writes:

"I have read with much interest your remarks on the N.M.C.F.U. meeting at Coventry. It was a crowded meeting of tired weary men, and it is not surprising that your representative, whom we were very pleased to see, has got a somewhat erroneous impression of the Union and its objects from remarks made by some individual members labouring under a sense of injustice.

The Position in Warwickshire

"I have laid it down very clearly at every general meeting that there is no petrol for recreative purposes—that is, joy-riding pure and simple—however much it may be wanted, and that decision, I am proud to say, has been loyally accepted by every meeting of members. We are indebted to Mr. Shrapnell-Smith for his visits to three meetings, in which he explained clearly and impressively the urgent need for economy, not only in petrol, but in every class of oil. The engineer in particular is appealed to, because he is always using oil in his work, and, consequently, could help much in the saving.

"I am bound to say that there is an unpleasant spirit abroad in Coventry. Who is responsible for it is not my business to enquire, but both the housing and food arrangements in Coventry are, apparently, worse than anywhere else. Thousands of workers cannot live in Coventry at all, and have to travel or walk a distance after standing twelve or more hours on their feet. They ask for petrol to enable them to reach their homes at night and come down to the works in the morning. This is the extent of the recreation, which, I presume, your representative looks upon as selfish and as trenching upon the needs of the country and the rights of other people. If that is so, then I have nothing more to say.

"During the time I was in Coventry I made enquiries as to the railway accommodation, and personally witnessed the ancient rolling stock which was trundled up and filled with munition workers, twenty in a carriage, on their way home to Warwick, Leamington, Rugby, Nuneaton, and other places, to which they must travel in order to sleep. Immediately afterwards I saw a director arrive by train and drive away in an elegantly appointed limousine. I do not begrudge this director his car, but if directors and employers in Coventry can ride home in motor cars, working men have the right to use their machines for the same purpose. [We agree—if the director was using his car *to go home*.—ED.]

"I am quite willing to show you privately full particulars of every claim which has been granted by the Controller, and I am certain that you would not only endorse every one, but agree with me that it is difficult to account for their not having been granted before. Upwards of four thousand munition workers' motor cycle licences have been renewed this year by the Petrol Controller without the intervention of the N.M.C.F.U. I think your representative did not quite grasp that.

A Doubtful Point.

"The quotation in italics with reference to bread contains the very words used by Mr. Shrapnell-Smith when appealing to the men to save all the oil possible. This article gives the impression that no munition worker is entitled to petrol at all under any circumstances. If this is what is meant it would be better to say so.

"As regards the men living two miles from the works, there has to be a minimum distance, and that minimum distance, to my mind, is two miles. A man who has to be on his feet twelve hours, in some cases fourteen hours, should not be called upon to walk four miles in addition.

"Another point on which your rep sentative has gone wrong is that effc are being made to interest branches the A.S.E. I never said anything of sort. I mentioned that in the tr I accidentally met a member the Executive of the A.S.E., and shown him the work which was be done, and he expressed his appreciati and said he would inform his branc so that men who were put to cert hardships might put their cases forwa

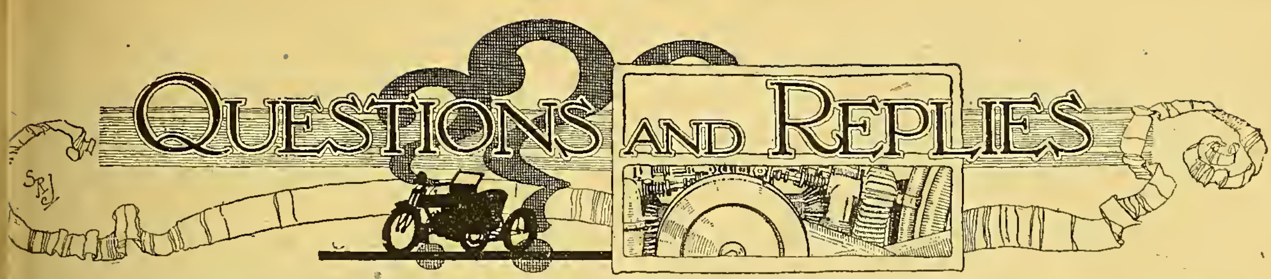
Glaring Inconsistencies.

"The men look upon going backw and forward to their homes as hea giving, and, in a way, recreative. you deny them this respite? You m tion inconsistencies. I will give some you do not mention. Six thous taxicabs are parading the streets London, many taking people to theat restaurants, home, etc., and this in a c where the means of communication unrivalled. Is that consistent with shortage of petrol? At Brighton, Ea bourne, Bournemouth, and other seas towns one sees large limousines for hi These cars are entitled to thirty gall of petrol per month, they are do nothing to help the war, nothing conserve the nation's stock of fuel, squandering it on purely pleasure a recreative joy-riding.

"The worst instance of criminal wa of petrol I have ever heard of was broug to the notice of the meeting on that v night. Hundreds of gallons of pet thrown away down an open drain, a this in Coventry. Small wonder the m are disgusted.

"Our efforts to impress on the men necessity of rigid economy are in the f of such facts rendered ridiculous."

[It was, we fear, perfectly true that mu petrol was being wasted in some of ways mentioned, and this natura caused the greatest indignation amo those who needed petrol for legitim purposes and could not get it.—ED.



QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Making a New Gudgeon Pin.

As I am having a new gudgeon pin made for my motor cycle, I am writing to ask you the following questions: (1.) Is cast steel a suitable material? (2.) If so, s it better hardened or left unardened? (3.) Do you think that ild steel, case-hardened, would be ore suitable? (4.) If cast steel is sed, is it liable to fracture under ormal running conditions? The pin s hollow, and is for a Triumph piston, nd the other day, in fitting a new pin f hardened cast steel, it broke in two ieces, and that is why I am anxious o know whether hardened cast steel s suitable or not before making anther one.—W.M.A.

(2, and 3.) It is best to make the lgeon pin of cast steel, which you y use either unhardened or very htly hardened. We think this would more suitable than mild steel. (4.) ; cast steel is not likely to fracture. e cause of breakage was probably due overhardening. It should not be ted to more than a dark straw colour en hardening.

Storing a Machine.

I am storing my sidecar combination. I have taken off the tyres, and, as I have no French chalk in which to place the inner tubes, have put them in ordinary hiting. (1.) Now, will this do s well as French chalk, as I do ot want the tubes to get perished? 2.) Is it also advisable to paint the yres with whiting before hanging hem up? (3.) Should I disconnect he wires from the magneto? If I do ot, is there any fear of the magnets ecoming demagnetised? (4.) Can a win engine be left with all four alves closed?—C.H.

(and 2.) Yes, your method of storing inner tubes should be quite satistory. The best plan is to keep the es in a dark, but slightly damp, ce, where they will keep good for a g time without deteriorating. It is worth while painting them. (3.) No, re is no necessity to do this. There not much chance of the magnets oming demagnetised. (4.) If you look fig. 6 on page 46 of the current tion of "Motor Cycles and How to nage Them," you will see a diagramtic view of a V type engine in which valves are closed, the compression oke just beginning in one case, and firing stroke having been just comted in the other.

Needle Valve Leakage.

The carburetter of my 1916 7-9 h.p. Indian leaks badly when the engine is running. I have lowered the petrol level, fitted a new needle and ground it in, and have assured myself that all unions, including the jets, are tight. I cannot locate the leak, but I suspect the pilot jet. Could you kindly oblige me with advice on the matter?—P.W.S.

Probably in lowering the level you have bent the arms a trifle too much, with the result that the float is not central and fouls the choke tube. Carefully verify this point. The correct level is $\frac{1}{16}$in. from the top of the jet. Your needle valve should not have been ground in, as it is made of brass and will not stand grinding in with emery. If it leaks at this point it is only necessary to tap it in at the top and rotate it in its seating. The pilot jet cannot leak.

The Importance of ORDERING "The Motor Cycle."

In response to previous requests the majority of the readers of "The Motor Cycle" no doubt have definitely ordered their weekly copies and now obtain them regularly from their own newsagents.

There are some, however, who still purchase copies haphazard from any newsagents' shop or bookstall that happens to be most convenient at the moment.

This latter method leads to waste, for several newsagents are then catering for the one purchaser, and there is the risk of copies remaining unsold.

The shortage of paper is now so serious that all waste must be avoided in the national interest to economise shipping space.

EVERY READER of "The Motor Cycle" who does not subscribe direct and has not yet placed a standing order with a newsagent is requested therefore to give an order at once and regularly obtain his copies in future from one newsagent.

An Old Type of Machine.

I purchased just recently a 6 h.p. twin-cylinder Vindec Special, and have great difficulty in starting. I have tried the controls in all positions, and even tried heating round about the jet. If I advance the spark I sometimes get popping in the silencer and sometimes a sort of back kick, but the engine does not fire properly. The ignition timing seems correct, and the valves and compression are in perfect order. Once the machine is started it runs perfectly, and answers quite all right. Can you give me the name and address of the makers?—A.L.

The cause of your trouble may be due to the engine being one of the older models with automatic valves. Petrol should be injected into each cylinder before attempting to start. Difficult starting is frequently due to air leaks at the carburetter and induction pipe unions. Perhaps you are attempting to advance the spark too far when attempting to start. The makers are no longer in business.

Bomb Dropping.

What is the actual course of a bomb when released from an aeroplane travelling at a speed of about 60 m.p.h.? I contend that the bomb when released will drop with a backward motion, caused by the pressure of air when released. A friend contends that a bomb when released is carried forward for some distance by its momentum, and then falls directly to the earth. An airman has therefore to release the bomb before reaching his objective.—A.H.

The bomb travels forward as the result of the kinetic energy obtained from the forward motion of the aeroplane. The actual amount of this forward motion would involve complicated calculations, which, to be accurate, would have to take account of the speed of the aeroplane, the weight of the bomb, and the varying density of the air. The actual path traced by the bomb would be part of a parabola, and would therefore never be actually vertical. Your idea that it would fall with a backward motion is quite without foundation. The motion might appear backwards from the aeroplane, but this is simply a case of relative motion, and might almost be regarded as an optical illusion. Consequently, a bomber should drop his bomb before reaching his target, and not when immediately above it.

Play in Twist-grip Control.

I possess a 1914 Indian, and I wish to take up the slack inside the twist-grip. Would you be kind enough to tell me how to get the twist-grip apart from the handle-bar? I have looked all round, but cannot see how the grips are attached to the bars. I might add the grips are of the long rubber variety.—H.G.H.

Evidently your handle-bars are of the touring variety. If this is the case you can push the rubber handle grip forward until a joint appears through the handle-bar. Remove the rivet from this joint and then pull the handle-bar grip backwards, when it may be detached. To take up the slack you should rivet up the joints in the flexible cable of the control.

Building a Cycle Car.

I am building a cycle car, and am faced with a difficulty which I should be extremely obliged if you could solve. I had intended to braze the rear hub spindles directly into the rear axle, the front and rear axles being on the same level, but owing to a cone forming part of the spindle, which would be annealed and spoilt in brazing, I must change my plan. (1.) Can you suggest any other method of fixing the rear hubs? (2.) Will it matter if, by the use of special lugs, I make the rear hubs a few inches higher or lower than the front hubs? Is this ever done in car construction, and if not, why not?—T.E.N.V.

(1.) The usual method in your case is to turn down the spindle, make fresh cones, and sweat them on after brazing the stub axles into the tube. (2.) It will not matter if the rear hubs are a few inches higher or lower than the front hubs. This is not done, however, because, unless the job is a makeshift one, there is no reason for so doing. The single modern exception is to be found in heavy commercial lorries.

Fitting a Front Drive Speedometer.

I notice in a recent issue of *The Motor Cycle*, page 279, you show a Harley-Davidson with leg shields, and, what is more interesting to me, there is a front drive speedometer fitted. How has the owner been able to fix it? I may say that my attempt to fit one has beaten me. I have tried all ways, only to find, after about 1,000 miles, the cable smashes off short, close to the lower attachment. The local H.-D. agents told me they had come to the same conclusion—*i.e.*, that it was almost impossible to get the cable to stand any length of time. I have noticed that there is quite an oscillating movement on the bracket that carries the small gear wheel, and this is due to its being fixed to the hub spindle and the lower girder.—E.W.

While we agree that speedometer drives are not all that can be desired, with a little attention it is quite possible to make the cable stand up for a considerable time. You may be interested to hear that we know of a rider who has been using a front-drive Smith speedometer on his Harley-Davidson, the cable of which has stood up for about 6,000 miles. The following hint may be of use to you: Wind both ends of the cable carefully for a length of about 3in. with insulating tape, so as to prevent it from breaking away at the ends. Also have the speedometer clip sufficiently slack on the handle-bar so that a very bad bump will allow it to give slightly without throwing a strain on the cable. The Harley-Davidson Motor Co. inform us that they have about one hundred front-driven speedometers fitted to machines which they have sold during the past twelve months, and the percentage of complaints has been very small.

Licences.

I have bought from a private owner a second-hand lightweight to supplement my heavier sidecar combination. Kindly enlighten me as to the following two questions: (1.) Can the previous owner transfer his Inland Revenue licence with his machine? (2.) Will one driving licence cover the two machines?—L.J.

(1.) No, the local taxation licence is not transferable, and applies to one particular man, enabling him to keep and use a machine. You would therefore have to take out a fresh one. (2.) Yes.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD

A Variable Pulley in conjunction with a Three-speed Gear.

(1.) What would be the benefit of fitting a Philipson pulley to a 1913 Armstrong three-speed hub, as I may want to use a sidecar later, the local roads being good? Some time ago you advised a correspondent to fit one. (2.) Would an engine-shaft two-speed gear be any advantage? If so, in what way? I want to keep the long belt drive, as I much prefer it to the countershaft chain and belt. (3.) Could I fix a handle-bar control to the clutch bracket to operate by hand, or would a Bowden control be better and easy to fit? If so, where would it be procurable, and what would it cost?—T.U.B.

(1.) It would mean that, instead of having three speeds only, you would obtain an infinitely variable ratio between two points on any speed which was in engagement in the Armstrong, which we think would be a distinct advantage. (2.) No, the extra friction of the engine-shaft gear nullifies its service. (3.) In peace time it would be easy to get a Bowden control to actuate the clutch, but at the present time we fear this would be exceedingly difficult. We regret we cannot tell you the cost.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☛ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

A.J.S.

1916 A.J.S., 2¾h.p., 3 speeds, lamps, horn, numbers, etc.; £46.—Cross, Jeweller, Rotherham. [X3830

A.J.S., 1917, 6h.p. 3-speed, special War Model, fitted with 700×80 tyres; £92.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter. [3520

A.J.S., 2¾h.p., 2 speeds, clutch, kick starter, new tyres, accessories, excellent condition, mechanically sound; £38.—Pearn, Kelsie, Birchfields Rd. S., Manchester. [X3811

A.J.S. 1916 Combination, 6h.p., splendid outfit, all accessories, spare wheel, hood, screen, etc., £97/10; 2¾h.p., 2-speed, £34; E.P. or exchange.—Service Co., 292, High Holborn, London. [X3885

A.J.S. Motor Cycles.—Immediate delivery of Military model, complete, detachable wheels, 700×80 tyres; £91/6; trade supplied; no permits required.—P. J. Evans, sole agent for Birmingham and district, 87-91, John Bright St., Birmingham. [4307

A.J.S., 6h.p., and sidecar, with wind screen, lamp, and horn; this is one of the latest 1915 models turned out, as it left the works in October, 1915. The outfit has been thoroughly overhauled and revarnished, and is practically equal to new in every possible respect; price only 70 gns.—Julian, 84, Broad St., Reading. Biggest light car and motor cycle dealer in the South. 'Phone: 1024. Closed Wednesdays 1 o'clock. [0735

The Gas Traction Committee.

IN the report of the Gas Traction Committee recently held under the chairmanship of Sir Boverton Redwood, some interesting recommendations were made with regard to the use of coal gas in motor vehicles. Of most of these our readers are already aware. We note that the Committee recommends the official reckoning of 250 cubic feet of gas of a gross calorific value of 490-500 British thermal units per cubic foot as the equivalent of one gallon of motor spirit, and on this consumption ratio gas at 4s. per thousand cubic feet is equivalent to motor spirit at 1s. per gallon.

They also recommend that the gas inlet to the container of any vehicle in general use should be of iron gas-pipe, 2½in. bore, screwed externally with British standard pipe-thread to take a union of that size of pipe. They further recommend that a charge of 2d. per 100 cubic feet should be levied for filling, with a minimum charge of 6d. when the filling is done at a filling station or depot.

When a flexible container is carried on a trailer the fabric of the container should be protected by a separate covering of canvas or other light material, stretched over hoops or other sufficient support of wood or metal.

There should be a positive cut-off valve and automatic non-return valve between the flexible container and the point of gas delivery to the carburetter intake or the induction pipe.

One of the most important observations of the Committee is the following: It is undesirable that semi-rigid containers of rubber and canvas or other proofed material should at present be allowed to be charged with gas to a pressure greater than 90 lb. to the square inch, or should be of a larger internal diameter than 4in., and even with these limitations containers of this class are, in the opinion of the Committee, unsafe if not properly armoured with galvanised steel wire of 0.012in. diameter (No. 30 B.W.G.) The Committee also recommends that experiments should be permitted and encouraged by the authorities for the construction or use of semi-rigid containers of woven wire up to a pressure of 300 lb. to the square inch, and it is desirable to encourage forthwith a limited number of experiments of a commercial scale with compressed gas in rigid metal cylinders, plain or wire wound, of pressure up to at least 1,800 lb. (120 atmospheres) per square inch.

The Fuel Question Again.

ON another page in this issue we mention some of the main points of the address given to the British Commercial Gas Association by Sir Robert Hadfield, F.R.S. There is, of course, much in this report that does not concern the motorist's aspect, but there is no harm in emphasising the possible close connection between the coal gas and the motor fuel industries. As we point out in our extracts, benzole depends for its existence in this country almost entirely on the coal gas and allied industries. But in Germany this dependence is very much diminished by the existence of a well-organised and prosperous dye industry. Another point that Sir Robert made was that Germany had enormously increased her trade in this respect, so that whereas once upon a time, and that only some twenty years ago, she was dependent upon us for most of her raw materials, she was now practically self-supporting in this respect, and we were largely dependent upon her for the finished articles for which those raw materials had been required—the dye trade materials.

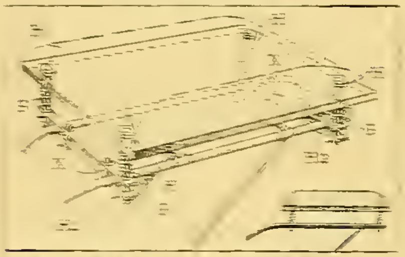
We have in our pages already emphasised the enormous value the dye trade has been to Germany as a source of motor fuel and explosives in the present war, and we have no hesitation in commending to our rulers this address of Sir Robert Hadfield as expressing in a nutshell a very important situation that we must watch with every care both at once and after the war.

IDEAS: Useful and Ingenious.

A SIMPLY DESIGNED SPRING PILLION SEAT.

THE pillion seat described was fitted to my motor cycle last year. It is a very simple yet effective contrivance, the parts that are necessary being four bars of steel, say, [illegible]in. × [illegible]in., and about 3in. longer than the extreme width of the carrier; also four long bolts or studs about [illegible]in. diameter screwed at both ends and about 5in. long.

Procure four ordinary cycle saddle springs and a thick board about [illegible]in. thick, and about as wide as the length of the above-mentioned steel bars. The length will be according to requirement.



A useful design for a spring pillion seat.

Drill [illegible]in. holes in the bar as near the ends as possible; also holes along the bar so that they just clear the inside of the carrier, as at X X. Next drill the board and push through the studs, and put spring and washers on H H. Bolt the bars to the carrier and fix nuts E, E. Note the bolts G, G move freely with the spring play through the holes in the ends of the bars; the bolts X, X, hold the bars firmly to the carrier.

The only thing necessary now is to pad and upholster the board.—H. [illegible].

ALTERATIONS TO A P. & M. KICK-STARTER.

THE kick-starter on a P. and M. cannot be called one of its strong points—at any rate, I have at times had trouble with the machine in this respect.

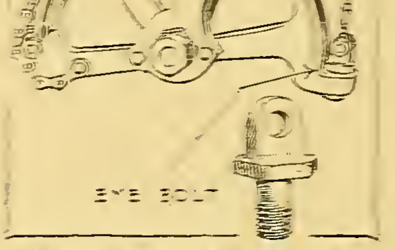
There is a legend which seems to have gained a good deal of credence, that the P. and M. engine is a low-compression one. I personally consider its compression anything but low, and even with the half-compression engaged there are times when a very considerable strain has to be put on the kick-starter to get the engine on the move.

The weak points I have found are that the bolt to which the chain is anchored at the front end of the quadrant is much too frail for its work, and tends at first, finally breaking off; then the ratchet teeth inside the half-time box are apt to jump each other, especially if the chain is a little too tight, and that the crank pin on which the rider's foot pushes is much shorter than the width of the average boot, and there is nothing to keep the foot from slipping off. My foot has slipped off several times, and when this happens one is apt to give one's ankle a nasty jar.

To remedy the breaking of the anchorage bolt, I fitted a flanged eye bolt with a [illegible]in. stem, drilling out the quadrant to suit; this bolt is tightened right down on to its flange, thus relieving the shank of the bolt of any bending moment; this destroys the value of the bolt as a means of adjusting the tension of the chain, and to take up the slack in the latter I have, when necessary, inserted a bolt of suitable diameter between the chain and the quadrant near the point of rear anchorage; the more the chain stretches the larger the diameter of the bolt that must be used.

To remedy the slipping of the ratchet teeth, I removed both the sprocket-shaft, which is carried in the timing case cover, and also the toothed nut which is screwed on to the crankshaft of the engine, and found that both sets of teeth had practically no undercut on them; they were neither of them dead hard, and could just be touched with a file, so were filed up to give a small amount of undercut to both of them.

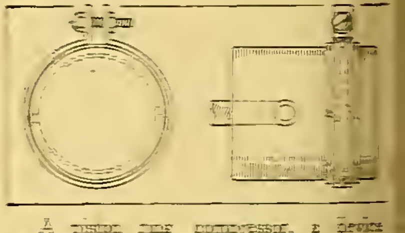
The foot pin was then taken in hand and a piece of [illegible] × 14 S.W.G. steel tube 4½in. long fitted just to push tightly on the existing pin. One end of this tu was belled out as shown, and the insi of the tube and the outside of the exis ing pin were both carefully cleaned a tinned with ordinary solder. The tu was then driven on (the belled end bei on the outside), and the two par sweated solidly together; this could done with a blow-lamp or large solderi iron, but I was able to put them bo into a bath of molten solder, which, addition to effecting the necessary fixi together of the two parts, coated t bare tube with a film of solder and made it unnecessary to nickel plate enamel it. This tinning of steel par with solder renders them quite rustpro—very much more so than ordinary pr sent-day electro-plating; it can be do at home, and if carefully done, and a superfluous solder wiped off while t article is warm, the effect is very mu that of unpolished nickel plate.—F.B.



Details of alteration made to P. and M. kick-starter.

INSERTING PISTON IN TH CYLINDER.

A DIFFICULTY is often experience when assembling an engine aft overhauling, in getting the pist rings to enter the cylinder.—



A piston ring compressor, a devic facilitating the insertion of the piston int the cylinder.

Obtain a piece of sheet steel 2in. longe than the circumference of the pisto ¾in. broad, and about $\frac{1}{16}$in. thick. Dr a [illegible]in. hole at either end, then bend the following manner:

Mark off 1in. from either end an bend at right angles after the mann of sketch No. 1, then place the piston top and bend to the same shape sketch No. 2. Insert a [illegible]in. bolt throug the two holes, and screw on a nut.

Place the band over the two rings in sketch No. 3, so that half the ring is showing; then draw the ba taut by means of the nut on the scre

Enter the piston in the cylinder un the band stops it from going furthe slacken off band, push piston further till the next ring stops it, place the ba on that ring in the same manner as t first, until finally all the rings are ente and the piston is in the cylinder.—G.J.M.R. (Dumbarton).

OCCASIONAL COMMENTS

BY "IXION"

Valve Spring Fixing.

I SHOULD estimate that valves have been responsible for more troubles on aero engines during the war than any other single detail. To some extent these troubles have arisen from factors which are not present on motor cycle engines—for example, the use of very light valves, air-cooled cylinders of abnormal size, and so forth. But I cannot help thinking that the pierced valve stem and cotter method of fixing the spring cap is obsolescent, and I wonder whether it will be retained on motor cycle engines after the war. A common method consists of turning three annular grooves on the valve stem, and shaping a couple of split cones to fit the grooves internally; the split cones are then locked to the stem by the spring cap under pressure of the valve spring, and when the spring is levered up the stem, the cones drop off and the valve is free. Such a system avoids weakening of the valve stem and simplifies the removal job.

Gudgeon Pin Fixings.

SIMILARLY, the number of new inventions in the way of gudgeon pin fixings is legion, though a few engines, including some of the best, retain he old grubscrew, which has cost so many of us a ong push ere now. The practice of fixing the pin in he little end of the connecting rod and fixing the ushes in the piston bosses is growing. I have yet o see anything better and simpler than pushing a soft teel or copper tube through the pin and burring the nds over.

Rotary Oil Pumps.

MUCH of the prejudice against mechanical oiling on motor cycles is due to the use of ball valves, which did not prove too reliable in the small izes to which motor cycle engines were restricted. Fast-running gear pumps stand up surprisingly well, ut add another mechanical movement, which some iders consider objectionable. There is now a sweet ittle pump on the market, which cannot be described or the moment; it is of the rotary type, and could asily be accommodated on our engines. It is cheap o make, absolutely silent in action, and as reliable as nybody could wish.

Spare us One Designer.

THE last three paragraphs are straws which show which way the wind blows. They may serve to indicate that most of the old conventions have een shattered by the war; that a new school of petrol ngineers has arisen, most of whom are young men nd unknown to fame in the pre-war motor trade—ven in the car trade. If a few of them can be ragged into the motor cycle trade after the war we hall get a very healthy infusion of fresh blood, which will stimulate an industry formerly in some danger of getting groovy. Of course, the obvious danger is that the best of these new men will enter the higher walks of engineering when peace returns, especially if the aviation industry continues to develop as men like Lord Montagu and Mr. Holt Thomas prophesy it must. The motor cycle trade could find magnificent opportunities for two or three of these men, and it is fervently to be hoped that we shall secure them.

Half-guinea Carburetters.

I NEVER secured a decent carburetter for the eight shillings which "Cairnock" regards as a rational price, but I well remember purchasing a 10s. 6d. float-feed from Gamage's in the very early days. It replaced a curious little abomination concealed inside the tank of my 2 h.p. Werner, which boasted a special compartment with knife-like edges for the purpose. Since then, doubtless for excellent reasons, the price of the simplest types of float-feed has advanced to the neighbourhood of £3. There is rather more metal in them nowadays, and they are more scientifically shaped and dimensioned, but the extras secured for the additional cost really amount to piston valves in lieu of a butterfly throttle and rotary disc air inlet, and handle-bar control instead of a bit of rod split-pinned to a lever stuck on the tank. There *ought* to be some money in carburetter making these days, but I have no doubt the manufacturers can prove that they barely pay their way.

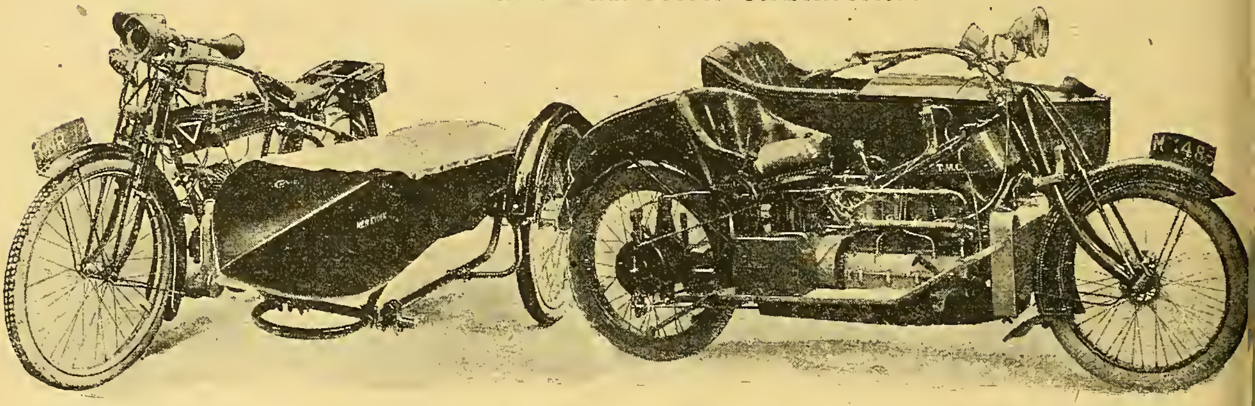
Too Technical?

AS I studied sundry expert contributions to *The Motor Cycle* of April 11th, I noticed, first of all, that the war has made our popular weekly far more technical than it used to be; this, because so many of our readers have advanced their technical education through training in various engineering corps. Secondly, it occurred to me that the technical conscience is a very restless and fastidious organ. For example, we have Mr. Mackay bewailing the inefficiency of the two-stroke, and "Wharfedale" lamenting over the horizontal couple of the flat twin; and both of them were thoroughly justified—from a technical standpoint. In actual riding, nobody minds the inefficiency of the two-stroke, and nobody notices the horizontal couple of the flat twin. If somebody markets a big air-cooled two-stroke (say, a 4 h.p. vertical single) which will keep cool, it will sell like hot cakes, because it has a pleasant exhaust and is easy to look after. As for the F.T. four-stroke, it is apparently going to boom after the war because it is vibrationless, and because its practical defects are less obtrusive than those of the single and the V. More power to the elbows of the plucky engineers who are striving to improve these promising engines. But our standpoint, as riders, is that with all the faults which experts can find in them, we love them still.

THE POST-WAR SIDECAR OUTFIT.

Possible Types with the Main Points of each considered.

EXTREMES IN SIDECAR OUTFIT CONSTRUCTION.



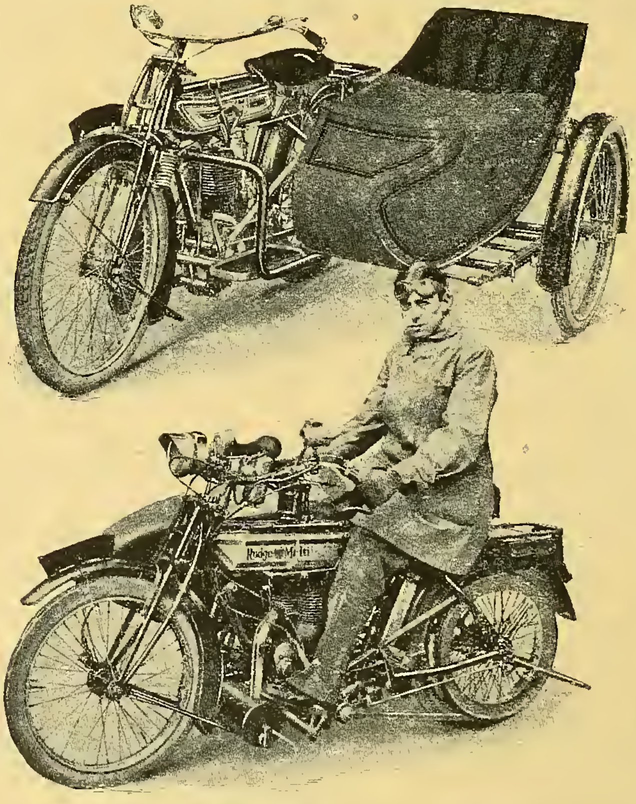
The combination on the left is a two-stroke, to which is attached a very light sidecar. Needless to say, any very serious touring is out of the question with such a combination. On the right is a water-cooled four-cylinder, which, as may be seen, is quite at the other end of the scale.

THAT one man's meat is another man's poison is never nearer to the truth than when we consider the almost equal number of supporters of the single and the twin. Hence in this article no attempt is made to find the ideal motor cycle for a sidecar combination, nor even a type most suitable for the majority.

The Question of Engine Power.

When one enquires of a friend the type of machine he will have after the war, the reply sometimes is a superficial quotation of the makers' horse-powers. One man may say "a 3½," another "a 5-6," a third "a big twin." In many cases, especially with those who were only just taking up the pastime when war broke out, riders have but a hazy idea regarding "types" as distinct from "sizes." One man may have had satisfactory service from a "3½" single but has fallen in love with a friend's twin, and intends to combine his ideal "size" with his friend's "type." We think it is generally agreed that, as a rule, to give the same power as a single, a twin must have at least 25% larger capacity.

TYPES OF SINGLE-CYLINDER SIDECAR OUTFITS.



(Top) The 3½ h.p. outfit, a well-tried type which will have many adherents after the war.

(Bottom) The big single attracted many people, because considerable power was coupled with the utmost simplicity of design.

When a rider advocates a "5-6" or "6-7" twi very often the mystic numerals are taken as size whereas if he went deeply into the matter he may fin that some of the nominally smaller engines are larg in capacity than those t which the makers ha given a higher nomin power.

To remove these an malies makers shoul come to some decisi among themselves to sta dardise a unit for pu poses of "nominal sizing" their engine and for this purpose unit of 100 c.c. capaci per h.p. appears to t the most simple, and, f that matter, approx mately correct also f normal type engines.

The Single.

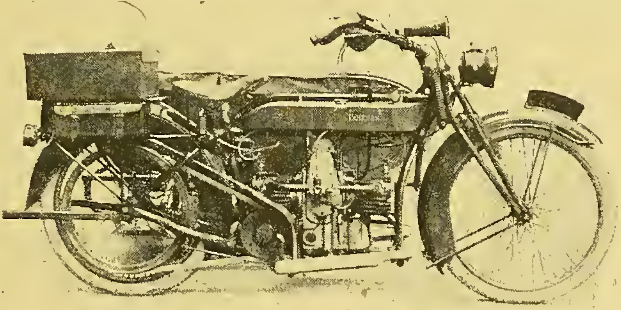
Taking the singles firs those who prefer the co parative simplicity of t "single lunger" may ha a variety of machin from which to choos At the present time the are three sizes availabl The 3½ 500 c.c. clas the medium size su as the Triumph, B.S.A and James "fours;" a the "big" single, class represented by t Norton "Big Four the Rudge 5-6, and t Excelsior 8.

he Post-war Sidecar Outfit.—

The engine sizes of these machines are as follow:

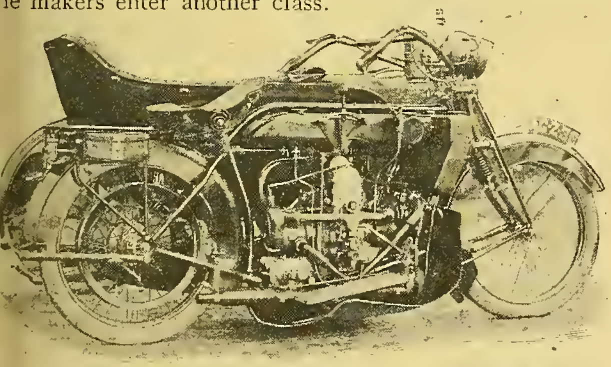
½ Class—		
Many makes	85× 88	499 c.c.
Iedium Class—		
Triumph 4	85× 97	550 c.c.
B.S.A. 4¼	85× 98	557 c.c.
James 4¼	86×103	600 c.c.
.arge Class—		
Norton Big 4	82×120	634 c.c.
Rudge 5-6	85×132	750 c.c.
Excelsior 6-7	96×112	800 c.c.

In the single class the "3½," so popular before he war, is the smallest engine from which one may xpect any degree of satisfaction. One may say, in act, that the 500 c.c. engine is too small for sidecar vork, but, provided the loads carried are fairly light, he country in which it is used not too hilly, and too nuch in the way of high average speeds is not xpected, this size will give a great deal of good ervice. We think, however, that a slightly larger ngine will be favoured more after the war: the size nown as "the four," and termed here the medium ingle. The few extra cubic centimetres in the apacity of the cylinder make a surprising difference, vhich shows that with a 500 c.c. "3½" one is running iearer the limits of its power than is desirable. The iedium single undoubtedly is a truly satisfactory idecar machine, and, rovided such luxuries as wo-seater sidecars with ood and screen do not orm part of one's post-var requirements, will ive as much all-round atisfaction as a larger iachine, unless the rider s keen on high speeds nd aspires to take every teep hill at a fast pace.



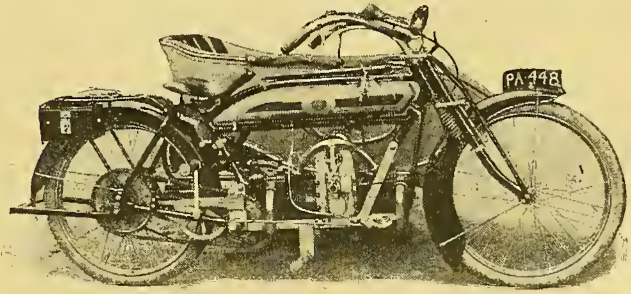
A flat twin outfit of 4 h.p., which will be an attractive sidecar outfit to many who desire a smooth running engine and a double purpose mount.

As regards the "big ingle," there is a marked endency for makers to bandon this type. It is ractically certain that the Norton large single will be post-war machine, but so far as can be ascertained t the present time it appears extremely doubtful hether the other large single cylinder machines will e marketed. If they are abandoned their place in ll probability will be taken by large twins, hence ne makers enter another class.



The 6 h.p. flat twin is a proposition that many makers will seriously consider after the war. Already there are half-a-dozen hat are, or have been, on the road.

The Twin.



The 3½ h.p. flat twin and sidecar. A 500 c.c. twin is on the small size for sidecar work, but is capable of giving great satisfaction under fair conditions.

In the twin class we have a greater range, both in size and choice of make. Beginning with the Douglas flat "four," there are many different sizes going up to approximately 1,000 c.c., both in the V and the flat types. Below the 594 c.c. 4 h.p. size there are other twins used for sidecar work. The 500 c.c. V twin was becoming very popular when war broke out, but usually the 500 c.c. twin does not give the same power as the 500 c.c. single, and as the latter is generally under-powered for sidecar work, one may rule out the twin of this size as being below the mark of practicability.

This class of machine can be divided into two types—those with V and those with flat engines. In the V division we have a large selection ranging in size from approximately 650 to 1,000 c.c., and nominally termed 5-6, 6-7, 7-8, and 8 h.p. The first three sizes mentioned may be termed the middle weights, and the last the 'big twins." The middle weights probably give all the power necessary for any class of sidecar work and are comparatively inexpensive to run, while the big twins give a large reserve of power, which, while being unnecessary, is a luxury well worth the cost if it can be afforded.

In the "flat" division the sizes begin with the Douglas 4 and go up to the Williamson 8, with such machines as the Brough 5, Humber 6, Matchless 7 in between, and as, theoretically at least, the flat twin has certain advantages, such as perfect balance, even firing, etc., there is little doubt that it will be a very popular type in the future.

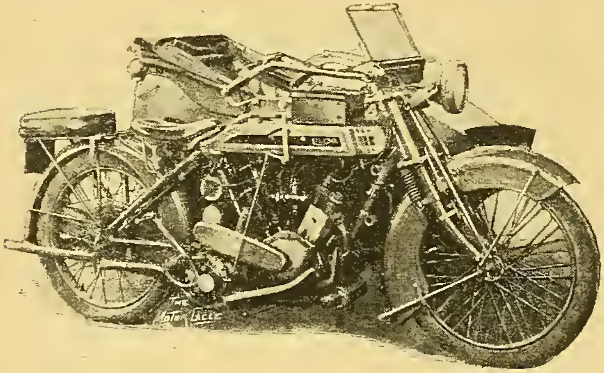
The Four.

There is one more type to be considered, the four-cylinder machine, and although no British makers at present market such a proposition, there is a marked tendency for riders to favour the type as a sidecar machine-de-luxe. If this tendency develops, it is to be hoped that British manufacturers will come forward with a suitable design, as no one will care to see the topmost class of motor cycles an imported article.

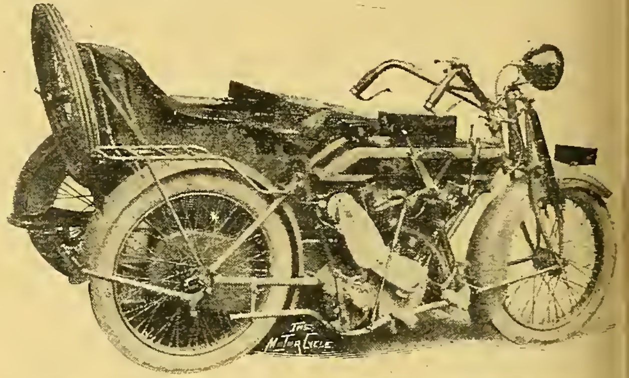
The Post-war Sidecar Outfit.—

As regards the sidecar part of the combination, almost every rider agrees that we still have a long way to go before the makers can write finis to their designs, and there is a strong feeling that combinations should be designed as combinations—a sidecar in every way suitable for the machine to which it is fitted—and not units designed and built by separate firms as a universal pattern. One sees more sidecars fitted incorrectly to their machines than those which are in true alignment, with the result that the majority of sidecars on the road to-day have earned for the sidecar combination the appellation of "unmechanical."

TYPES OF POWERFUL TWINS.



The 5-6 h.p. combination, possibly the most favoured class of passenger motor cycle.



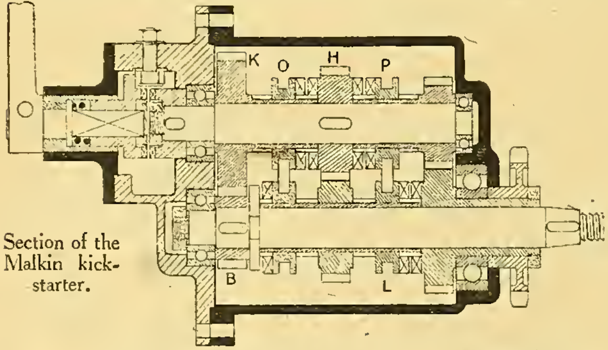
The powerful 8 h.p. twin has many adherents, and there is much to be said in favour of possessing plenty of power.

AN IMPROVED FOUR-SPEED GEAR.

Modifications to an Attractive and Original Design.

In our issue of February 21st (page 176) we described and illustrated a four-speed gear box incorporating a kick-starter, designed by Mr. B. Malkin, of Leith. Mr. Malkin has recently somewhat modified his original design, and we reproduce an illustration of the gear box in its latest form below.

The designer writes: "Since making the original drawings I have hit on an idea for a kick starter which still further simplifies the gear box. The engine is started with L and P in neutral and O in engagement with H. A ratchet collar is fixed on the end of the layshaft, which can engage with another on the kick starter. These are normally held out of engagement by a small roller acting on the inclined face of a projection on the kick starter collar. The first movement of the kick starter allows the two ratchets to come together, and the engine may then be started through the wheels K and B."

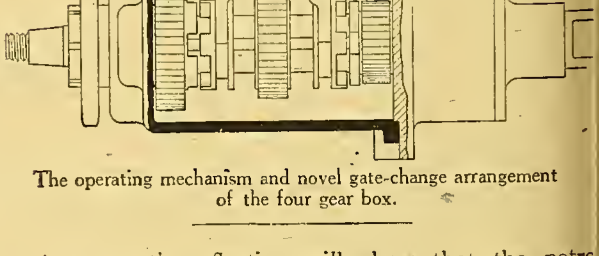


Section of the Malkin kick-starter.

Operating Mechanism for Four-speed Gear.

The gear itself is operated by a gate change of somewhat unusual design. The bar B can receive an oscillating movement and a sliding movement from the change speed lever. The ball-ended lever A can oscillate, but is prevented from moving on end, and is mounted on a squared portion of the bar.

The right-hand pair of clutches are operated by the sliding movement of the bar, and the left-hand pair by the oscillating movement of the ball-headed lever in the inclined slot in the fork.



The operating mechanism and novel gate-change arrangement of the four gear box.

A moment's reflection will show that the petro shortage must survive the war by a tolerable period. The various Services will have inconceivable tons o stores to tidy up. The world's aeroplanes will not b left to rust just where the signing of peace happen to catch them. Sunk tank steamers will not bo merrily up to the surface when peace is declared. Th dear old days will not return, nor Dora decease, th instant the Kaiser cries "Kamerad."

LONG v. MEDIUM STROKE ENGINES.

Some Comparisons made on the Basis of Equal Cubic Capacity.

IN his recent article, "The Case for the Long Stroke," Capt. Lindsay made quite a convincing statement on behalf of his favourite type of engine from the standpoint of the practical rider. The main factor which vitiates his arguments, however, is that in no instance is a definite comparison made between a long and a medium stroke engine identical in all respects save that of stroke-bore ratio. The engines Capt. Lindsay selects for comparison are by different makers, or else they are of different cylinder capacities, or run at different speeds. Indeed, the assumption throughout is that the long stroke engine will be a slower running machine than its competitor, which is distinctly unfair to the short stroke engine. Speaking as a mere theorist, I think, too, that Capt. Lindsay deals too cavalierly with us in dismissing our efforts with the words, "The theorists have told us all about it." A good deal has admittedly been written on the mathematical aspect of the question, but hardly all that *might* be written.

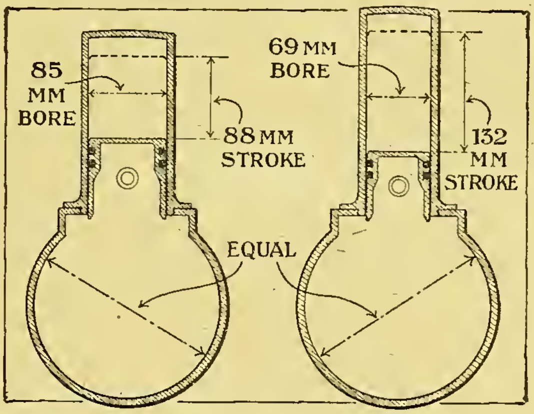


Diagram showing relative sizes of the two engines discussed in this article.

Even the few suggestions that I propose to offer will tend to show that the unprejudiced theorist can bring forward much additional evidence in support of Capt. Lindsay's conclusions. The armchair investigator has the advantage over his colleague of the broad highway, inasmuch as he can adopt from the outset what is, after all, the only rational and impartial plan, *i.e.*, to compare what may be termed average engines of each class, putting them on the same footing, as far as possible, in every respect; for I take it that the object of the enquiry is not so much to decide whether the long stroke "Eureka" is a better machine than the medium stroke "Primus," but whether the long stroke principle is more scientifically sound than that embodied in the rival engine. Let us, then, consider two engines of equal cylinder capacity, speed, and horse-power, the stroke of one engine, however, being one and a half times that of the other. For convenience the medium stroke champion will be assumed to have a bore and stroke of 85 mm. and 88 mm. respectively, while the corresponding figures for the long stroke representative will therefore be 69 mm. and 132 mm.

Since it is postulated that the explosion pressures in the two cylinders are identical, manifestly the total thrust on the piston of the medium stroke engine—for brevity, piston "M"—will be one and a half times the thrust on piston "L." It is not unreasonable to make the further assumption that the designer of the typical engines we are considering will proportion his bearing areas to suit the loads which fall on them. Consequently we may expect the gudgeon, crank pin, and main bearings of "M" to have one and a half times the area of the corresponding bearings in "L"; this will ensure that the bearing pressures *per square inch* are identical, which in its turn implies that the corresponding bearings in the two engines will wear equally well. An exception may perhaps be made in the case of the gudgeon pin, the greater arc of swing of the "L" connecting rod possibly being responsible for slightly greater wear in the "L" small end bush than in the "M" bush.

(a) Balance.

Coming now to the question of centrifugal pressures, it may be said at once that the rival engines are so nearly on an equality in this respect that careful enquiry must be made if a just decision is hoped for. Since these forces vary directly with the weight of the reciprocating parts, it will first be necessary to make an estimate of the relative weights of the typical engines we have selected for consideration. If we assume that all the dimensions of the "L" reciprocating parts bear the same proportion to the corresponding dimensions of the "M" parts as do the respective cylinder bores, we can say at once that the weights will vary as the *cube* of the bores—that is, that the "M" parts would be $\frac{85^3}{69^3} = 1.86$ times as heavy as the "L" parts. It is extremely improbable, however, that this relation will hold; for example, the thickness of the metals of the two pistons would be practically the same, instead of varying with the bore. Arguing on these lines, it would be found that the weights would vary as the *square* of the piston diameters, *i.e.*, weight of "M" parts $= \frac{85^2}{69^2} = 1.5$ times weight of "L" parts. The real relation between the weights will lie somewhere between these values, and in the absence of more reliable guidance we cannot do better than take the average, leaving us with the result that if "L" parts weigh 1 lb., "M" parts will weigh 1.68 lb.

We are now in a position to calculate the actual extent of the centrifugal or inertia forces. As has been shown in these columns, a single-cylinder engine under even the best conditions will always be out of balance to the extent of at least one-half of the maximum inertia force. In the present instance, since the speeds are the same in the two engines, the unbalanced forces will be proportional to $W \times R \times \left(1 + \frac{R}{L}\right)$, where W = weight of reciprocating parts, R = crank length, and L = length of connecting rod. If we take $L = 5 \times R$ in the case of "M" engine, we shall have $L = 3.33 \times R$ in "L" engine (assuming the rods to be of the same length). On substituting the

Long v. Medium Stroke Engines.—

various values in the formula, we are left with the result that the unbalanced force in the long stroke engine is 0.97 times the force in the medium stroke machine, or, in round numbers, they have identical values! Put more simply, the balance in the two engines is equally good (or equally bad)!

(b) Wear.

The effect of this rather remarkable result on the amount of wear likely to occur in the two engines is very problematical. Although the actual inertia forces are roughly the same in both cases, the bearing *pressures* due to these forces will undoubtedly be more severe in "L" engine on account of the smaller area of its bearings. But it must be remembered that during the compression and explosion strokes the inertia forces act more or less in opposition to the forces due to the pressure of the compressed or ignited gases on the piston; consequently during these periods the net amount of wear on the bushes is practically independent of the inertia pressure. In any case all fear of excessive wear on this score can be eliminated by allowing a slightly more generous bearing surface than is necessitated by the mere explosion pressures.

(c) Mechanical Efficiency.

On a "first approximation," as the mathematicians have it, the short stroke engine has the advantage in this respect. Taking the loss of energy in piston friction as being proportional to piston stroke × piston circumference, we obtain relative values, for "L" and "M" respectively, of 28,600 and 23,500. No account is here taken of the reduced length of skirt of the "L" piston, with its accompanying reduction in the area of oil film to be sheared; so that actually the figures would not be quite so favourable to the medium stroke engine as the above values appear to indicate. Besides, the friction loss in the rotating parts—crank pin and journal bearings—will unquestionably be less in the "L" engine, not only on account of the lighter loads which fall on them, but because of the smaller radius at which the friction acts, due to the reduced diameter which may quite safely be given to these rotating elements. On the whole, therefore, and in the absence of experimental data, we are scarcely justified in claiming a score for the "M" engine on the ground of overall mechanical efficiency.

(d) Cooling.

This is a characteristic in which theory is entirely in accord with Mr. Lindsay's practical conclusions. For purposes of rough calculations we may say that the area exposed to atmospheric cooling effects is proportional to piston stroke × piston circumference + piston area. On this basis we find the long stroke engine to have 32,340 units of cooling surface, as against only 29,160 units for its competitor, a clear gain of about 11%.

(e) Compression.

Since the area of the path of escape open to the compressed gases in the cylinder varies directly with the piston diameter, it is clear that the long stroke engine will retain its compression longer than the medium stroke type, or, rather, the proportion of gaseous mixture escaping past the rings will be less in the one case than in the other.

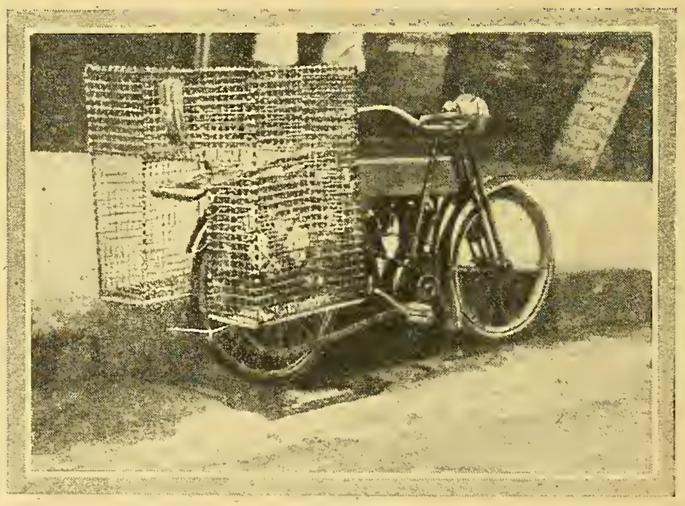
To sum up, then, it can be said with confidence that the short stroke engine possesses no single feature in which it scores decisively over its rival; so that evidently the secret of its popularity must be sought in a region inaccessible to the mathematician. And since these influences are therefore most probably based on individual prejudices and opinions, there is every prospect of many lengthy and exciting discussions occurring before the question is finally settled—if ever it is!

MOHANDIS.

◆

Carrying Light and Bulky Luggage.

An ingenious luggage carrier for motor cycles has been devised by a Los Angeles man who is engaged in delivery of light but bulky merchandise. The device is composed of heavy wire mesh, and hangs low on both sides of the rear wheel, giving unusually large space for the contents. The luggage carrier will carry almost as much as a sidecar and is cheaper, but it is questionable whether anyone but an expert rider could manage a big load in the traffic of city streets, to say nothing of driving in grease.



A wire luggage carrier of ample dimensions used for delivery of light goods.

Although the idea is, to say the least, unconventional, there is more in it than one may imagine at a casual glance. There is no reason why a wire carrier should not be introduced in place of the usual heavy wooden sidecar body. A much larger space would be available, and weather-proofing would be quite a simple job. Those who so vigorously decry passenger carrying on the luggage carrier will have much to say, but even so we may be regularly seeing this luggage-carrying device in use.

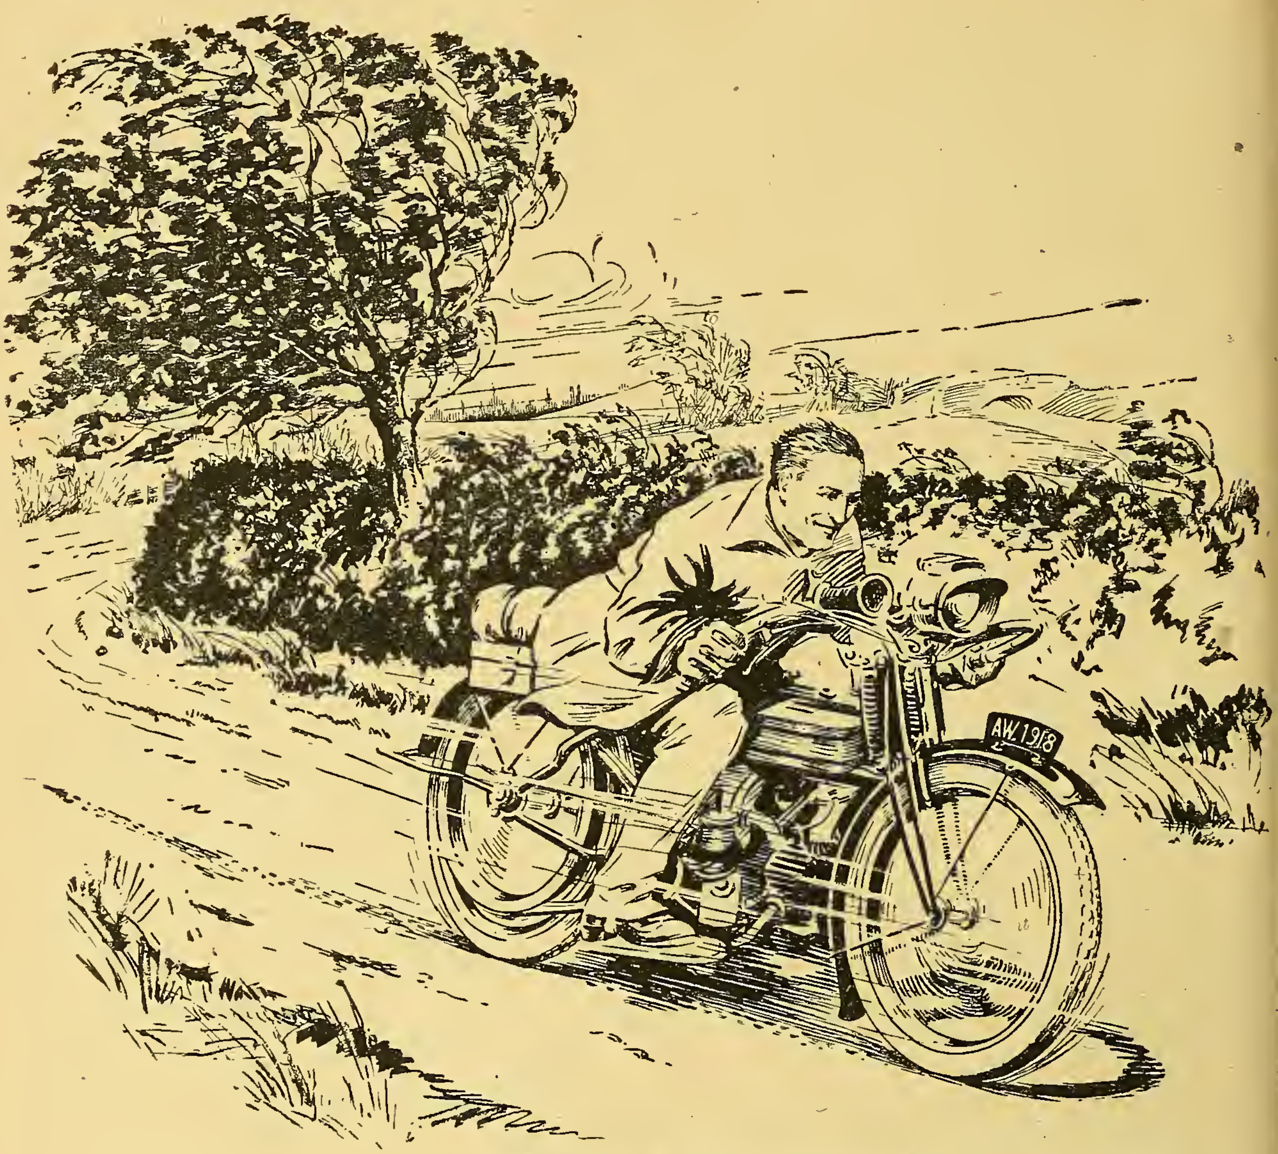
Easy Starting
Under All Conditions

"The other night the bike was left out from 12 a.m. to 8 a.m. in a blinding rain storm. When I got to her in the morning she started up with the first kick."

Extract from a letter received from Dr. G. H——, of Shetland.

Art Catalogue post free.

ARIEL WORKS, Ltd.,
3, BOURNBROOK, BIRMINGHAM.



LET me ride with the wind on my forehead,
The beat of the air through my hair!
Let me face the rush of its passing—
The open, sweet, God-given air.

Let me face the wind in the evening,
Let its coolness revive my soul;
Let me pass from the glare of the pavement
To places where God makes men whole.

Let me feel the wind on my temples
When I answer the Last Great Call;
Let my spirit go out in a windstorm,
Clean, pure, on my last ride of all.

MILITARY NOTES.

Motor Cycling in Tropical Africa. Battle of the Tanks.

DELAY IN THE MAILS.

' is expected that there will be considerable delay in the arrival of mails which left Egypt on April 4th, conning about a fortnight's correspondence m Egypt and the Palestine Front. ssibly some of the mails have been lost.

* * *

IE NEW MILITARY SERVICE BILL.

R. MACPHERSON was asked in the House of Commons what arrangements, if any, would be made that men called up under the new litary Service Bill, who, from their alifications in civil life, would be elig- for officers, could obtain commissioned ık; also, whether time-expired men o, when they left the Army, had oh- ned non-commissioned rank, if called under the provisions of the new Bill, uld take the rank they occupied when y obtained their discharge. He replied it both matters were under the con- eration of the War Council.

* * *

THE POST-WAR SIDECAR.

GT. WILLIAMSON, R.E., writing from France, speaks of the days before the war and the fascination choosing a new mount. He writes: Ve get a glimpse sometimes of what might have been. Occasionally one is able to forget, and for a few moments indulge in flights of fancy. Of the horrors we have been through recently, I will not speak; no doubt you have heard plenty of stories.

"As I write, my thoughts go back to 1913. In April of that year I remember hesitating a good deal whether I should buy a single or 5-6 h.p. for sidecar work. I finally decided on a 4 h.p. Triumph, and many times during the summer regretted I had not plumped for the extra power, although the single behaved admirably. Without any doubt whatever, I shall go in for the big twin if I get through this nightmare all right. Nearly all my riding in France has been on singles, and I crave heartily for the big twin. That reminds me of a discussion I read some time ago in *The Motor Cycle* on the question of big twin outfits. Someone asserted that the 8 h.p. sidecar outfit was doomed, and that people who could afford such a combination would spend a little extra and go in for the cheap light car. My own opinion is that such an idea is rubbish. There will not be a four-wheeler comparable in reliability and speed with the powerful sidecar. The sidecar will for me always have a greater fascination than the cheap four-wheeler, and I guess many other motor cyclists will echo these sentiments."

THE BATTLE OF THE TANKS.

MR. PHILIP GIBBS, the *Daily Chronicle* special correspondent, in his narrative of the Battle of the Tanks, in the recent fighting round Villers-Bretonneux and in Hangard Wood, says:

"German tanks, though heavier than ours, with bigger guns, have now beaten a retreat, leaving one of their type in No Man's Land. It has a high turret and thick armour plates, and is steered and worked on a different system from ours. One of them was killed by a tank of our old class, and then we put in some of our newer, faster, and smaller types, which can steer almost as easily as motor cars, as I know, because I have travelled in one at a great pace over rough ground. These set out to attack bodies of German infantry of the 77th Division, forming up near Cachy. It was a terrible encounter, and when they returned this morning their flanks were red with blood.

"They slew Germans, not by dozens nor by scores, but by platoons and companies. They got right among the masses of men, and swept them with fire, and those they did not kill with their guns they crushed beneath them, manœuvring about and trampling them down as they fell. It seems to have been as bloody a slaughter as anything in this war."

* * *

FROM NYASALAND.

AN interesting letter has reached us from Lt. G. W. Mathieson, of the South African Motor Cyclist Corps, Nyasaland. In it he speaks about the difficulties encountered by the despatch riders in Central Africa, and, judging from the photographs he sends, one can easily understand the difficulty of motor cycling in that country. Obviously it is no pleasure trip to be trekking in Nyasaland.

Lt. Mathieson says that *The Motor Cycle* still reaches them, and generally goes the round of the camp.

MOTOR CYCLING UNDER DIFFICULTIES IN TROPICAL AFRICA.

(Top) A very bad incline, necessitating a rope and four men to manœuvre the machine. Such hard going tests one's riding abilities to the utmost. Slippery black earth with tree roots over the path are quite the usual thing.

(Bottom) A typical jungle path. The dense undergrowth has frequently to be cut away before a passage can be made.

Call for Women Orderlies.

Women orderlies are urgently required for military hospitals in France.

British Postmaster at Jerusalem.

Sgt. Frank H. Smith, R.E., is the first British Postmaster at Jerusalem.

Motors in Singapore.

The 1917 imports of motor cars and motor cycles into Singapore are reported to be more than 75% larger than during 1916.

The County of Middlesex Motor Volunteer Corps.

With further reference to an appeal for motor cyclists from Mr. K. Ballard, the County of Middlesex Motor Volunteer Corps, Central Group, 406, Euston Road, London, N.W.1, which appeared in last week's issue, we have had another communication from this gentleman, urging the great need of motor cyclists at the present time. Their services will not be required at the moment, but only in the case of extreme national need, such as a threatened invasion, but it is most essential for the military authorities to know upon whom they can call in the event of an emergency.

Three Motor Cycles for £9.

At the auction sale at Woolwich on Thursday last week of "unserviceable and obsolete" ordnance stores, Lot 178, "three motor cycles," fetched £9, and forty-three magnetos, sold in lots of ten, fetched £1 each. A Russell motor car realised £12 10s., and "5 cwt. of old motor cycle belts" £4. 25 cwt. of old motor cycle tyres £16 10s., and 12,000 boxes of Tyreroid for £12, seem to tell a tale.

600 Cwt. of Motor Cycle Tyres!

Lots 67 to 72, 600 cwt. of motor cycle tyres, were withdrawn, although catalogued as having been on view at the A.O.D. Stores, Angel Mills, Edmonton. Other lots included 2,500 motor tyres, plain and studded. In lots of 100, they averaged about £25. Inner tubes fetched £2 to £3 more. Cycle fittings, frames, rims, brakes, forks, and handle-bars, motor lorry wheels, batteries, "vices of sorts," old boots, rope, iron, wood, etc. Most of the stores had been on view at Woolwich Arsenal and dockyard.

Boys no longer accepted for the R.A.F.

We are informed by the Air Ministry that the enlistment of boys between fifteen and seventeen years of age in the R.A.F. is no longer possible, and that this branch of the Service is closed indefinitely. Lads between the ages of seventeen and eighteen years, preferably with technical experience and capable of doing a man's work, can be enlisted as such, and paid at the rate of third-class airmen, namely, 2s. per diem.

Anglo-American Commercial Relations.

In order to facilitate the development of trade between this country and America, a Committee on Laws and Arbitration has been set up. The object of this committee, which is working in conjunction with the American Chamber of Commerce in London, is to effect the setting up of a body for arbitrating in any commercial disputes that may arise between firms in this country and in America. Either would be suspicious of a decision given in the other's law court—the average Englishman's opinion of American justice is proverbial. The scheme is not simple of accomplishment, but there is every hope of success.

Special Features.

POST-WAR COMBINATION.

LONG v. MEDIUM STROKE.

A.I.D. LADY D.R.'s.

Interest in Motor Cycles.

We frequently meet soldiers and e
soldiers, who had no interest in mot
cycles prior to the war, who now displ
keen interest in motor vehicles generall
and many, no doubt, will join the ran
of the motoring fraternity.

A Plea for the Merchant Service.

We certainly think a great injusti
is done to officers and men of t
Merchant Service, who are doing su
magnificent work and undertaking gre
risks in keeping the country suppli
with food and other necessaries at t
present time. As matters stand at t
moment petrol is only granted to offic
and men on leave from the Army a
Navy from foreign service or from t
Grand Fleet, but we certainly think th
the Merchant Service should receive d
consideration in this respect.

A machine gun being fitted to a sidecar for use in an emergency. (*Official.*)

Var Services.

The Women's Legion is now to be nown as the War Services Legion.

etroleum in Brazil.

Engineer officers have discovered in he State of Parana, Brazil, a rich leposit of petroleum, which is to be vorked by the State.

verseas Trade.

A committee has been appointed to dvise the Department of Overseas Trade Development and Intelligence) on matters elating to the activities of the department.

Iotor Tandems.

Some of the first motor cycles were andems. Considering the vogue in illion riding, it is surprising that Patent Office patrons have not designed modern motor tandem.

ady Motor Cyclists Wanted.

The Women's Legion, 15, Pall Mall East, London, S.W.1, is still open to eceive as recruits lady motor cyclists f good education who have had some xperience in riding. At the present ime there is no difficulty in obtaining nexperienced drivers, but those who ave had, say, four months' driving are ot so easy to procure.

ishop calls up Clergy.

Though the clergy have been exempted rom the new Military Service Bill, the ishop of London intends to call up hose in the Diocese of London who vould have been liable had the Bill een passed as it was originally drafted. Ie declared that exemption was not esired by the clergy.

Motor Car for Sixpence!

Those who want a chance of obtaining four-seater Wolseley motor car for 6d. hould write to J. Pepper, of Pepper's arage, 63, Piccadilly, Hanley, Staffs, ho is presenting one of these famous rs to the Hanley Red Cross effort. The raw will be conducted by the officially ppointed Prize Drawing Committee on une 29th, 1918, at the Town Hall, Ianley, and the winning number will be nnounced in *The Motor Cycle*. Applications for tickets should be sent to the ddress given above.

etrol for Sailors on Leave.

It has already been stated in these ages that petrol is granted to soldiers n leave from Overseas, and sailors on ave from service at sea, but as there eems to be a little doubt in the minds f some people as to how matters are rranged as regards the officers and men f the Royal Navy, we may state that e Petrol Controller's Department endeavours to treat the Navy men in exactly e same way as soldiers.

Officers and men from the Grand leet only get their leave at comparatively rare intervals, and these present difficulties, but officers and men oing certain work which gives them a ort respite on shore—say once a month—cannot have petrol licences granted to em on every one of these occasions, d it may be safely said that short-time etrol licences to officers and men on ave from the Fleet are only granted, y, once every four months.

Canadian Motor Cycle Show.

An exhibition of cycles and motor cycles will be held from May 4th to 11th at the Auditorium, Montreal, under the auspices of the Montreal Bicycle and Motor Cycle Dealers' Association.

Commendation for Motor Cyclist Specials.

Sergeant Freedman and Constables S. C. Willshear and S. C. Rathbone, of the motor cycle detachment of the Special Constabulary, London, have been commended for plucky service.

Motor Cycle Stolen.

About 3 p.m. on Saturday, April 20th, 1918, a twin-cylinder Harley-Davidson was stolen from outside the Canadian Records Office, 15, Tudor Street, London, E.C.4. The registered number is LR 3881, engine number L17, T5366. A reward of £10 will be paid to anyone giving information leading to the recovery of this machine. Communications should be sent to Capt. J. S. Watkins, Canadian War Records Office. Telephone: City 3210, and Western 1309.

The Ladies of Pervyse.

We are pleased to hear that Miss Chisholme has almost entirely recovered from the effects of the gas poisoning to which we referred recently in this journal. The Baroness de T'Serclaes, however, is still in a nursing home, and has, unfortunately, not yet been completely restored to health. Beautiful coloured photographs of these two ladies were shown at the exhibition of war photographs at the Grafton Galleries, Bond Street, London, W., which closed last Saturday.

Coal Gas.

Of late we do not hear much about motor cycles with coal gas installations.

The Ramsey Oil Well.

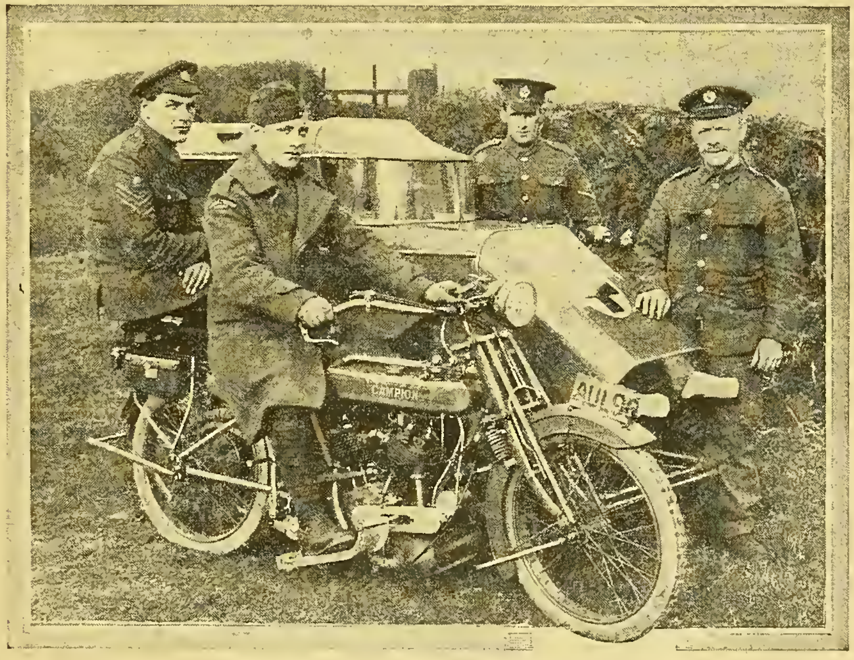
Ramsey's well continues to yield from two to three gallons of oil daily. No Government action has yet been taken.

Road-making after the War.

One of the peace aims of the A.A. and M.U. is to bring about "the employment of the Army on road making during demobilisation." What will the Citizen Army think of this? We all want good roads, but to suggest that they be built by the defenders of civilisation shows poor appreciation of their services.

"Ixion" and Lubrication.

A few weeks ago our contributor "Ixion" referred to Reg. Holloway's ride from Coventry to London on a single pump-charge of oil. We are reminded that Maj. Holloway—for such is his rank now—charged his crank case with about a tumblerful of oil, then emptied his oil tank. For the first few miles stops were made every few hundred yards to clean the sooted plug. The distances between stops grew greater every time until about twenty miles out of Coventry he was able to proceed without trouble. Holloway rode slowly; at no time did his speed exceed 15 m.p.h., and the distance covered was about 110 miles, when the crank case was found to contain about half the fluid put into it at Coventry. We repeat our comment at the time, that no useful purpose was served, except to show the skill of the driver and to secure publicity for the makers of the machine.



A RED CROSS 8 H.P. AMBULANCE OUTFIT.

This unique sidecar is a recent production of Messrs. The Campion Cycle Co., Ltd., Nottingham, and permits the patient to lie flat or sit in a normal position. A semi-circular celluloid screen is fitted, which, with the hood, affords complete protection from the weather. The stretcher can be withdrawn from the rear of the sidecar.

Overseas Co-operative Trading after the War.

An Important Meeting on Overseas Trade.

THE second meeting of motor cycling and accessory manufacturers interested in this proposal was held at the Birmingham Chamber of Commerce on Thursday, 25th April, and was very largely attended.

Mr. Henry Sturmey was in the chair. Mr. Hamilton Wickes, late H.M. Trade Commissioner to India and Canada, and Mr. S. A. Paish, representing the Board of Trade and Foreign Office, attended specially. Mr. Hamilton Wickes explained the conditions obtaining in Canada, and made some most valuable suggestions as to the methods of trading which should be adopted.

Mr. Paish ably commented upon the alternative proposals which those present had under consideration, and promised active Government support in any scheme of a practical nature which might be submitted to that department.

After discussion it was unanimously agreed that a limited company should be formed for the purpose of putting a scheme into operation, and a committee of seven gentlemen representing influential interests in the Motor Accessory Industry was elected as a sub-committee to draft Articles of Association and to submit proposals as to the details of organisation.

The Motor Cycle Trade and the I.A.E.

WE have on several occasions dealt with the efforts being made in various quarters to encourage the scientific point of view in industry. It has occurred to certain members of the motor cycle trade that the Institution of Automobile Engineers, which contains some of the leading experimenters and car designers of the day, is incomplete without representatives from the motor cycle industry. There are, as a matter of fact, in the motor cycle trade at the present time some very capable men—men full of ideas worthy of publicity. At the present time, these men have no inducement to join the Institution of Automobile Engineers, and there is no other means by which they could make their ideas so well known. If they do join and attend the meetings, they hear about nothing but latest developments in car matters. Motor cycles, as such, are practically ignored, and it is only when such a question as fuel is being treated that motor cycle interests are at all an essential feature of any paper. It has been suggested that if the Institution were to open its doors to motor cycle engineers as such it would be to the mutual benefit of the Institution and to the motor cycle trade.

The details of the scheme are as yet not formulated but, so far as it has gone, it is suggested that out of the papers at present read before the Institution of Automobile Engineers, a certain number should be on motor cycle topics, or the number of papers should be increased so as to include motor cycle topics. Also the degree of the Institution should be open to motor cycle engineers.

The scheme has our whole-hearted support, and we wish it the best of success. So far as we can see, nothing but good can possibly come out of it, so long as the necessary support is given unanimously by other members of the trade.

The Flat Twin Criticised.

HAVING read the notes of "A Tilter at Windmills," under the above heading, in *The Motor Cycle* of March 21st, I beg to respond on behalf of the windmills. Together with a senior contributor, whose wit and sound practical judgment I do not hope to rival, I have long advocated the flat twin as a type of engine of which the British manufacturer was safe in making a speciality, and recently I stated something to the effect that torque does not matter in the least within reasonable limits so long as the balance is good. Now, "A Tilter" states that "Torque is far more important than balance," and of all abortions on this flower-strewn earth he advocates the side-by-side twin, balanced as a single. In other words, he suggests sacrificing the simplicity, convenience, and cheapness of the single, to say nothing of its solidity of construction, in order to obtain torque equivalent to that of the flat twin!

In reply one need only ask why, if we are to employ two cylinders, we should place them in such a position that perfect balance is impossible when, by a different arrangement, we can obtain "A Tilter's" much-desired torque and perfect balance into the bargain?

But "A Tilter" gives himself away most horribly in his eagerness to induce one of the windmills to rise at the lure, which I obligingly have done. He suggests fixing one cylinder of the best flat twin going so that it cannot fire, and then seeing of what advantage is one's perfect balance as regards comfort when the engine is robbed of its even torque. Naturally the snatch is worse than with a single, and extreme discomfort is experienced, simply on account of the light flywheel. The more even the firing impulses the lower can be the effective weight of the flywheel, and thus we arrive at the fact that torque is a matter of flywheel weight rather than evenness of firing impulses. A 100 h.p. gas engine, firing once in ten revolutions, can be made to impart so even a torque that it can be used for lighting directly a house installation—simply because one can employ so large a flywheel that the firing impulses are of little consequence.

Let "A Tilter" ride a well-balanced flat twin, ge up to thirty miles an hour, and then cut out one cylinder, and, so long as his silencing is good, he will have no indication of the fact, except by the natural falling off of power.

CHINOOK.

THE MOTOR CYCLE AVIATION SECTION

The enormous importance of the Air Service needs no emphasis: it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouraging of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

600 H.P. Aero Engines?

Not so long ago, aero engines of 200 h.p. were spoken of with bated breath. Nowadays engines of 500 and 600 h.p. are freely discussed.

The Question of Armament.

With aeroplanes increasing in size, and engines getting bigger, why not bigger armament? Is there any outstanding reason why machine-guns of double the present size could not be used?

A Future for the Six-stroke.

While motor cycle manufacturers are busying themselves perfecting the two-stroke engine, aero engine designers are much more interested in the six-stroke principle.

Chief of Many Tribes.

Lt. J. R. Stacey, R.F.C., a Canadian, who recently met with a fatal accident, is said to have been a chief of the Iroquois Indians and of five other North American tribes.

The First Giant Sikorsky.

In 1913, I. I. Sikorsky, who is regarded by many as the father of the large aeroplane, completed his first big plane. The span of its wings was 28 metres with a chord of 3 metres. The length of the body was 19 metres, and in it were arranged comfortable cabins over which was a deck. The body was constructed of three-ply wood, while the landing carriage had eight wheels of the Nieuport type. The power was derived from four 100 h.p. Argus engines driving four tractor propellers. The complete machine weighed about four tons, and flew well with half its engine power. Mr. Sikorsky made some remarkable flights, and beat the world's record for weight lifting by aeroplanes per square foot of wing surface.

The Patriotic League.

Three aeroplanes, subscribed for by Britons resident in Pekin, Rio de Janeiro, and Nicaragua, have been presented by the Patriotic League of Britons Overseas.

AIRMEN MOTOR CYCLISTS

Flt.-Lt. Geoffrey Boyton, of the Ulster Centre of the Motor Cycle Union of Ireland, was one of the first men in Ireland to join up at the outbreak of the war. He sailed for France before the end of September, 1914. After a year's service as a despatch rider, he was granted a commission as an observer in the R.F.C. He was mentioned in despatches in the following June, and during the following month qualified for his "wings." Boyton has been engaged in most of the warmest parts of the line.

In pre-war days, Lt. Boyton was a well-known and enthusiastic motor cyclist, and was the first amateur to finish in the last Tourist Trophy Race.

Flt.-Lt. Geoffrey Boyton, R.A.F.

A Mere Bagatelle.

How many extra thousand pounds of expenditure has the new gradation list of the R.A.F. cost the country per day, we wonder?

Ten Years Ago.

It is interesting to read details of the flights of Mr. Orville Wright which took place ten years ago. One report says that on September 9th, 1908, he made a flight lasting fifty-seven minutes, and a height of 150ft. was reached. Later in the month a height of 300ft. was reached.

A Forty Miles an Hour 'Plane.

Mr. Orville Wright, in 1908, was not satisfied with the speed of his machine, and hoped, by altering his engine sprockets, to get 1,450 revolutions per minute. He thought by so doing he could obtain forty miles per hour.

Pioneer Work.

In 1908 a German Army airship made a record flight lasting thirteen hours, and the Malecot, a combination of aeroplane and balloon, made an ascent at Issy with four passengers and performed evolutions at a height of 450ft.

"The Flypaper."

Newcastle-on-Tyne has a flying paper of its own. Its title is appropriately *The Flypaper*, with "Some funny flights of fancy by flying men" as one sub-title and "A journal expressing the fleeting fancies of flying men" as another.

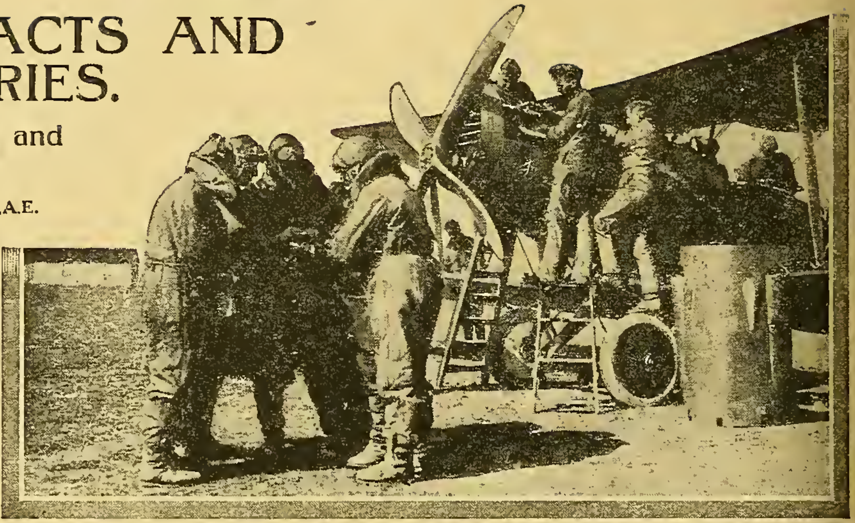
Private Flying in U.S.A.

In the United States a licence must be obtained by any person who contemplates flying near any place designated as a war zone, and as the whole of the United States is designated as a zone of military operations, private flying is impossible without a special permit.

FLYING FACTS AND THEORIES.

CONTROL II.—Tail-sliding and Rolling.

By W. G. ASTON, A.F.Ae.S., A.M.I.A.E.



Pilots discussing their orders while a battle-plane is being prepared.

When a loop is attempted but not accomplished, owing to the aeroplane having insufficient impetus to get on the top, it is forced to carry out a tail-slide, which from many points of view is not a particularly desirable manœuvre, nor is it easy to imagine circumstances in which it could fairly be described as a useful one. The machine is in the position shown in fig. 1, and is forced to drop backwards, inasmuch as the forward thrust of the screw is not able to cope with the weight of the aeroplane. Possibly at a future date, when the horse-power weight ratio has been greatly improved, there will be machines of sufficient power to enable a vertical climb to be carried out, but for the present such a performance is out of the question.

When the machine drops backwards the flat tail plane becomes the leading surface and the main planes become the trailing surfaces; also, since they are now travelling in the reverse direction, the tail has a greater angle of incidence than the main plane, and especially so is this the case if the elevators be kept in the position indicated at No. 1 on the sketch—that is to say, in the position into which the pilot will put them for performing his loop. In these conditions the centre of pressure will be somewhere between the tail and the centre of gravity, so that there will at once be formed a couple tending to right the machine and bring it on to an even keel, as shown in the second position of the sketch. The momentum of the aeroplane will probably carry it further into a position in which the tail is well up, as suggested at position 3 in the same figure. The energy of the tail slide will have now become partly potential, the remainder having been absorbed in resisting the thrust of the screw. The aeroplane is therefore now in a posture suitable for a recovering nose-dive, and this it will do all the more readily if the control-stick is now pushed forward and the elevators set at what will be a positive angle when the machine starts travelling nose first again.

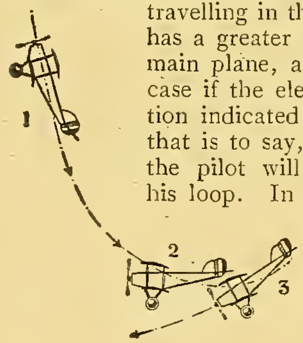


Fig. 1.

The Dangers of a Tail-slide.

There are two principal dangers in connection with the tail-slide. First of all, when the machine stalls going up on its uncompleted loop the pilot may not at once realise the steepness of his altitude. Now the ordinary treatment for a "stall" is to tip the nose of the aeroplane down with the least possible delay. To do this simply means pushing the stick forward and setting the elevators at a positive angle. If the machine has got past being corrected in this manner and now proceeds to tail-slide, it is obvious that the elevators will act as negative planes, as shown in fig. 2, and will consequently defeat, or at least try to defeat, the tendency for the aeroplane to right itself. Furthermore, as they will encourage the machine to dive more vertically they will enhance its diving speed, and, as they are now acting as *leading* planes and not as purely *trailing* planes, a very heavy load will be imposed upon them which may easily be more than they can stand. If, for instance, the elevator control wire breaks, the elevators will simply be doubled up underneath the tail plane, and the whole machine may easily be rendered uncontrollable.

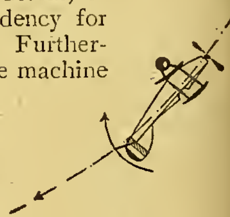

Fig. 2.

The wing flaps, or ailerons, undergo a similar risk of damage, for here again what were originally parts of the trailing edge become parts of the leading edge, with the result that the load and stress upon them are enormously enhanced, and may exceed the safe limit.

It does not always follow that the aeroplane when stalled on the loop tail-slides vertically; on the contrary, the probabilities are that it will be rolled a little one side or the other, and the resulting recovering action will be partly a tail-slide and partly a side-slip. This will, however, only partially relieve the strain on the elevators, and will not, therefore, alter the conditions of the case very materially.

The Roll.

A manœuvre which is comparatively modern, but is none the less highly effective and useful, is the roll, which can either be treated as a manœuvre complete in itself, or as one suitable for combination with others. The roll consists of differentiating the respec-

lying Facts and Theories.—

ive lifts of the wings to such an extent that the aerolane makes a complete revolution on its longitudinal xis. At first sight it might be thought that such a erformance could be carried out with great ease and ithout seriously deflecting the machine from its flight ath, but actually such is far from being the case. s will be shown, the roll is to all intents and purposes loop pulled out sideways, so as to form, as it were, ne complete turn of a corkscrew. That this is so is urther proved by the fact that during the roll the pilot s kept hard in his seat by centrifugal force, showing hat the axis on which the roll is described is not oincident with the axis of the aeroplane.

The reason for this is as follows. During the ottom 180° of the roll the main planes are in such a osition that heir lifting ffect is not as t normally is, in pposition to the orce of gravity, ut is in the same direction as gravity. It is clear, herefore, that if the machine were rolled completely ver when flying level in the ordinary way, it would uring half of the roll lose a very great amount of eight. It is true that an aeroplane, as Pégoud showed, can fly upside down, but to do this it requires to adopt such an attitude that its wings have a positive angle of incidence. Thus, if simply rolled over when flying normally, as suggested in fig. 3, it will not acquire this attitude.

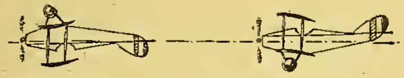

Fig. 3.

When a Roll can be performed.

There is, therefore, only one method by which the machine can be rolled over without serious loss of height, and that consists in carrying out the manœuvre when the aeroplane is "zooming"; in other words, when the aeroplane already has an impetus in an upward direction sufficient to carry it through that phase of the roll when the lift from the wings is negative. Such being the case, it is almost needless to say that the roll is a stunt which cannot be repeated indefinitely, inasmuch as it starts with the machine at full speed and ends with it practically at stalling point. At times I have heard claims put forward for two complete rolls on end, but the most I have ever seen, or that seems to be well authenticated, is one and a half complete rolls, but even that generally entails some little loss of height. The greater the ratio of power to weight the quicker will an aeroplane roll, and the greater will be the angle through which it can roll without losing altitude. A complete roll takes from four to seven seconds.

Aeroplanes by the roadside ready to bring reports of the enemy's positions. (Official.)

STEAMER LANES AND PLANE ROUTES.

EVERYBODY has heard of the "steamer lanes" across the Atlantic, and many landsmen imagine that they represent the most direct route. In actual fact, all the great ocean routes are determined mainly by the set of the currents. Ocean currents rarely exceed 2 m.p.h. in strength, but even this tiny resistance spells a difference of nearly 300 miles on a six-day voyage. When peace opens the door for commercial flight, conventional air routes will undoubtedly come into being, based on similar reasons. Steady currents of wind at 30 m.p.h. are common in some localities, and would be important in a long flight.

THE TRANSATLANTIC FLIGHT.

THE first Transatlantic flight is expected to start from Newfoundland and terminate on the Irish Coast, the distance between the two points being about 1,800 miles. The wind currents across the Atlantic average about 15 m.p.h. Travelling from west to east in normal air conditions, a 100 m.p.h. machine would accomplish the flight in rather less than fifteen hours. Starting in the opposite direction, under similar conditions, the same machine would require about twenty-one hours for the trip.

Thus a flight from America to this side is obviously a simpler proposition than is the return journey.

TAKING TIME BY THE FORELOCK.

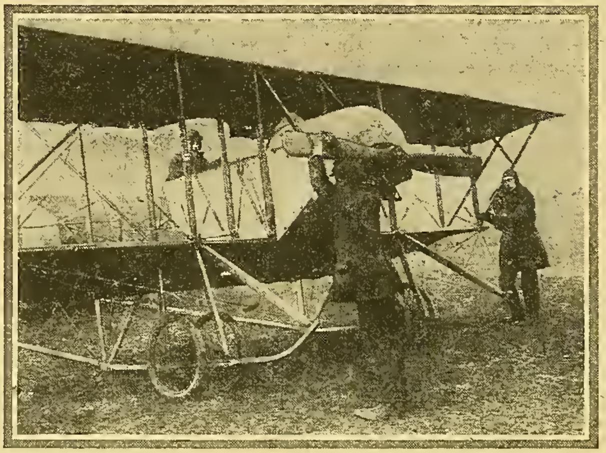
A School at which Youths can Learn to Fly before attaining Military Age.

By **CHARLES L. FREESTON.**

IN the ordinary course of events the embryo pilot does not obtain admission to an officer's cadet wing until he is 17 years and 11 months old, though he may make formal application a month earlier. His first flights, moreover, do not begin until he has been through courses of instruction in military duties, followed by others concerned with the technicalities of engines, rigging, and the theory of flight. Whether he is able to become a flying officer at all, however, depends upon a variety of considerations, and the selection of a man for service does not necessarily imply that he will be trained as a pilot.

Another Way.

There is a way, however, of materially increasing the chances of acceptance, and that is by learning to fly before making application. This means, of course, that tuition must be sought at a civilian flying school. If, while still under the eligible age, a would-be pilot can learn to fly and obtain a Royal Aero Club certificate, he has a very potent credential in his favour when he makes formal application for admission to an officer's cadet wing. The examining Board has no need to consider whether he is of the stuff that pilots are made of, for he has already secured his brevet, and he has merely to satisfy the Board on general grounds.



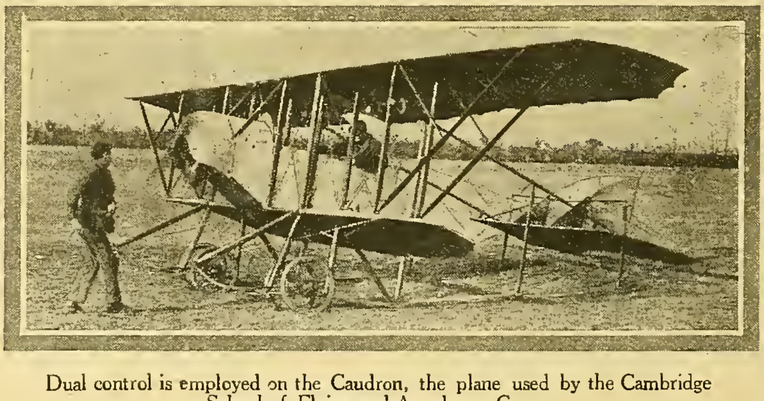
Preparing to start the Caudron tractor, which is fitted with a 50 h.p. Gnôme engine.

But where, it may be asked, is it possible nowadays to learn to fly, save at a naval or military school? Nearly every private flying ground has long since been annexed by the authorities. There are sundry exceptions, none the less, and one is the aerodrome belonging to the Cambridge School of Flying and Aerodrome Co., Ltd., of 30b, St. Andrew's Street, Cambridge. It is situate at Hardwick, a pleasant village a few miles out from Cambridge, where good living accommodation is to be found at a reasonable price.

A Suitable School.

From all that I saw there on the occasion of a recent visit, I may testify that the place is eminently suitable for the purpose, and that the school is conducted on sound lines. I was informed that for the most part the pupils have been young aspirants, patriotically eager to become Service pilots at the earliest possible date, and to present themselves ready armed with a certificate when they seek admission to a cadet wing. And let it be said, at once, that a considerable portion of the sum they have paid in tuition fees is refunded by the Government if they are successful in their application.

The aerodrome itself is about eighty acres in extent, entirely free from obstructions, and is surrounded, moreover, by a vast area of flat ground. Under the skilful and careful tuition afforded by the school instructors, the prospect of landing outside the aerodrome has rarely to be considered, but it is at all events consoling to know that the adjoining territory is not of a rugged or otherwise unsuitable kind.



Dual control is employed on the Caudron, the plane used by the Cambridge School of Flying and Aerodrome Co.

Instruction is given on Caudron tractor biplanes, with 50 h.p. Gnôme engines—a very suitable type for the purpose. Dual control, of course, is employed. As may be seen from the illustrations, the machines have double tail-booms and a *naçelle* body, and for school purposes this confers the great advantage that, in the case of a bad landing, the damage done can be repaired by the substitution of new tail-booms, whereas if the ordinary tractor fuselage were used structural damage would be more serio

A Three Months' Course.

The chief instructor and aerodrc manager was, until a few days ago, A. Assheton Salton, but he has tal up the testing of aeroplanes, and succeeded by Mr. L. Ry Knowles, a Service pilot of la experience, who is assisted Mr. B. J. E. Currey, a Hendon pilot. The system instruction is sound thorough, and accidents h been practically unknown dur the two years that the Ha- wick school has been in ex- ence.

Three months' tuition is gi if necessary, but as a gen rule a pupil obtains his Rc Aero Club certificate within to eight weeks. The govern factors are not merely his ind- dual aptitude, but the state the weather and the number days on which instruction possible.

The tests for a R.Ae.C. ce- ficate comprise two dista flights of at least tweny- furlongs, in the form of figu of eight, the landing to made each time within a gi radius of a marked point, and als *vol plané* from 100 metres (328ft.)

Mechanical Training.

In addition to learning to pilot aeroplane, the pupils are given ev opportunity of gaining a practical kn- ledge of the internal combustion eng the erection and repair of aeroplanes, general machine s practice. If interes in questions of the or design, they make arrangements private coaching at Cambridge offices of company under guidance of Mr. H S. Cuthbertson, business manager, was formerly the c designer and mathe tician of a Midl aircraft manufactu firm.

The ranks of m cyclists, it scarcely ne to be added, have duced a steady str of pilots of the class in the past; in f no section of the community has more useful in this important sphere. the present juncture new recruits more than ever needed, and the yc of to-day could have no worthier a tion than to seek to join the Royal Force, in which the opportunities individual distinction are greater tha any other arm of the Services.

A.I.D LADY DESPATCH RIDERS.

Work of the Women's Legion Recruits.

THE lady motor cyclists who are doing despatch riding for the Aeronautical Inspection Department are in rather a peculiar position. It might be naturally supposed that this Department, being directly under the Air Ministry, would employ R.F.C. drivers, but, in actual fact, the lady motor cyclists are recruited through the Women's Legion into the A.S.C., M.T., and are then attached to the A.I.D.

Their duties are to take officers and men to the various works for inspection purposes. Their journeys are mostly in London or, at any rate, in the London area, and they usually amount to some ten or twelve miles in length, while in the course of their duties they average from 150 to 200 miles per week. They are expected to do their own roadside repairs, change tyres, and clean their machines, but the more serious mechanical work is undertaken by six civilian mechanics under the charge of an R.A.F. corporal, who has served in France for over two years.

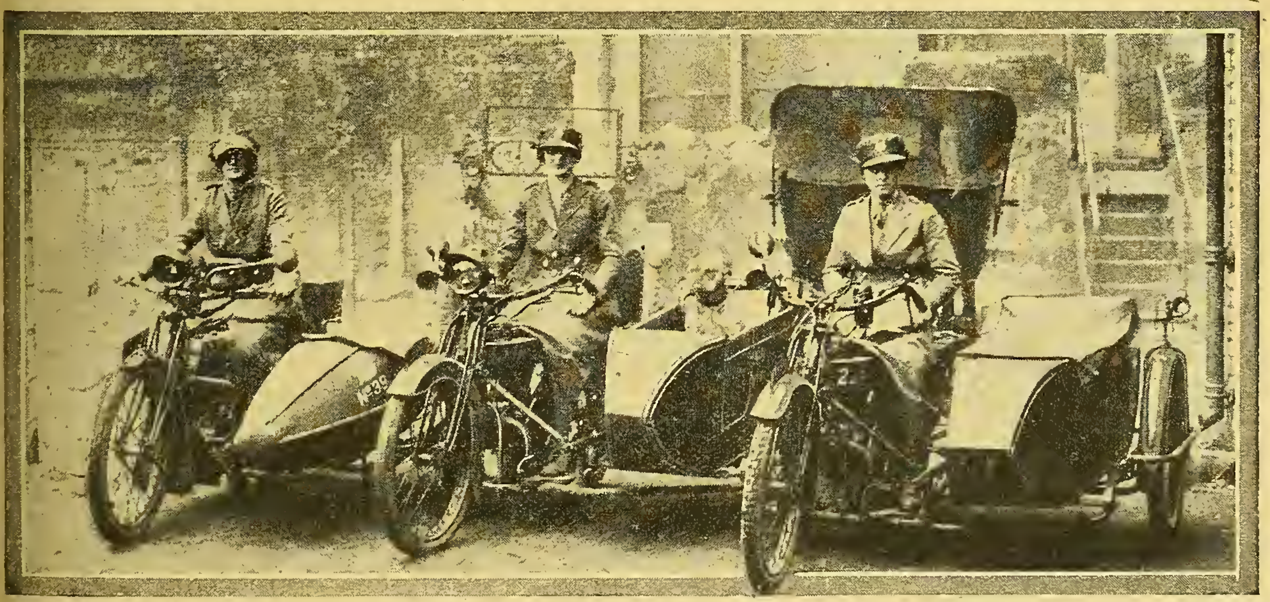
The officer in charge explained to us that the girls are splendid workers, and they very rarely complain. They have to parade at 8.45 a.m., and roll call is taken by the head driver. They are supposed to stop work at 6 p.m., but this very largely depends upon the exigencies of their duties. They have to carry on in all weathers, winter and summer, and, despite this fact, their attendance is excellent.

There are very few accidents. One, as a matter of fact, collided with a taxicab the other week and buckled the back wheel, but such incidents are few and far between.

Starting Big Twins.

We questioned several of the ladies regarding the starting of their engines, and, notwithstanding the fact that many of them are big twins, they experience very little difficulty in this respect. One lady whom we questioned had driven a car before joining the A.I.D. detachment, but had had no motor cycle experience, while another had never driven a motor cycle before joining up, had received instruction at the hands of the corporal, and after a week's tuition drove quite well enough to take people round on inspection work.

The time that the girls are not actually employed in despatch riding they usually spend in their workshop, watching how repairs are done and learning all they can about motor cycles. The machines with which they are provided are mostly 5-6 h.p. Clynos, of the famous W.D. pattern, while there is also a Triumph, which is fitted with a semi-racing sidecar body, and two W.D. pattern 4 h.p. Douglases.



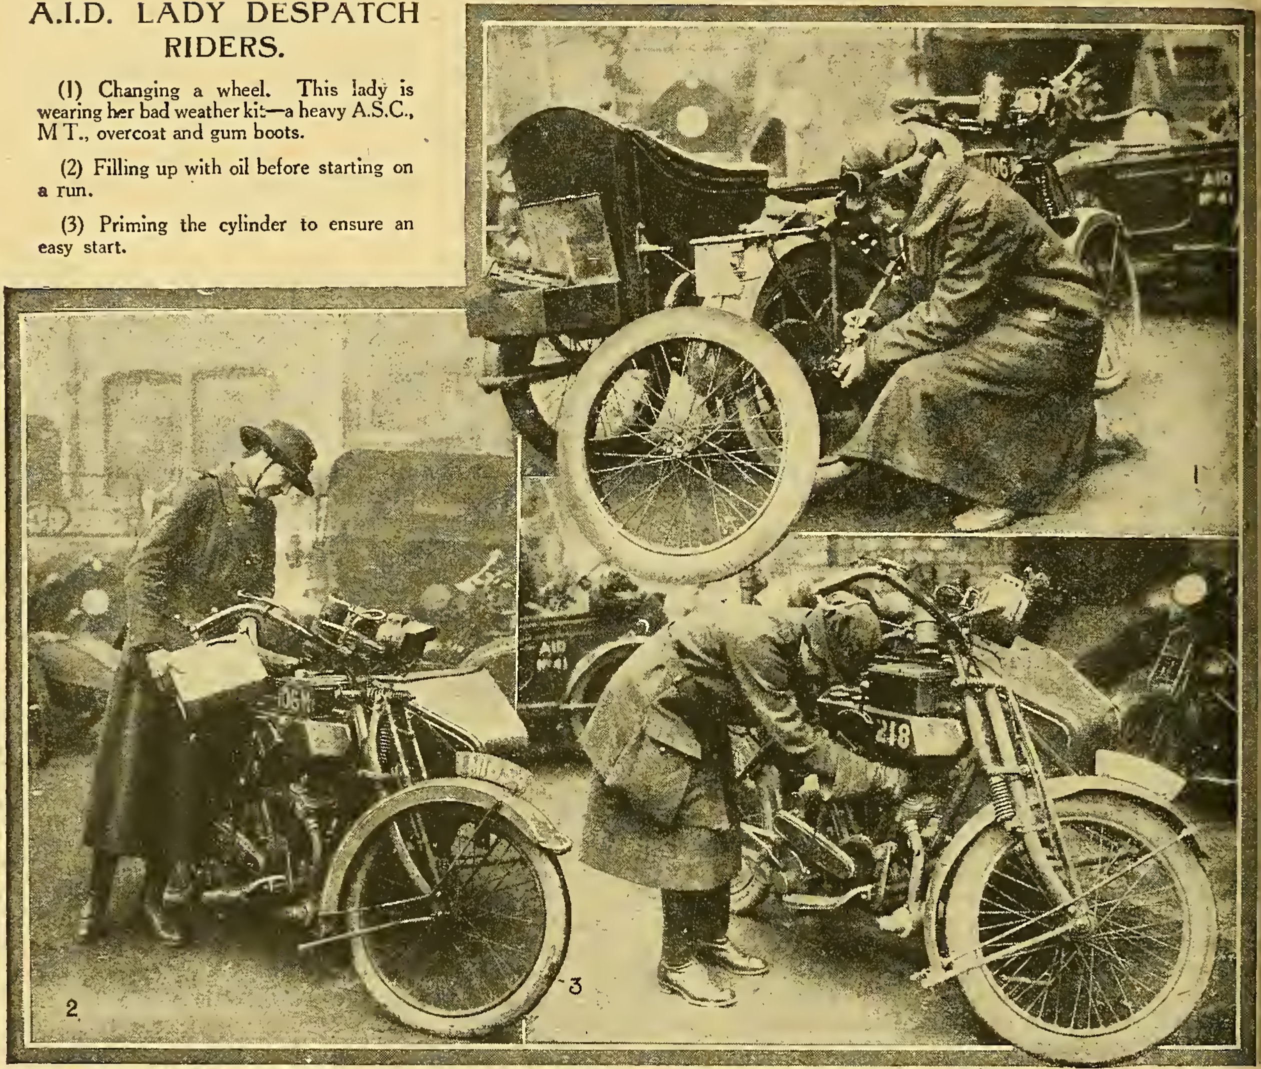
Three A.I.D. lady despatch riders. Two are mounted on 4 h.p. Douglases and one on a Triumph.

A.I.D. LADY DESPATCH RIDERS.

(1) Changing a wheel. This lady is wearing her bad weather kit—a heavy A.S.C., M.T., overcoat and gum boots.

(2) Filling up with oil before starting on a run.

(3) Priming the cylinder to ensure an easy start.



Christchurch Motor Cycle Carnival.

Motor Cycle compared with Horse Racing as a Spectacular Sport.

A CORRESPONDENT writes as follows in sending us an account of an event recently held in New Zealand. Alan Woodman, who figured prominently, is, of course, the rider who lost a leg while practising for the 1910 T.T.

“The carnival—held in aid of the Red Cross—proved the most successful event of its kind ever held in Australasia, and far ahead of any similar event I have ever seen. It was held on Stockburn Course, a fairly heavy grass track exactly a mile in circumference. Owing to heavy rains the meeting was postponed from February 16th to February 23rd, and was then held in perfect weather. A record crowd for the course was present, and the excitement was tremendous and continuous. It certainly showed what the possibilities were of motor cycle racing after the war, and left no doubt in my mind that it is destined to become, with the provision of proper tracks, as great a sport as horse racing. The sight of nine or ten motor cycles tearing round the track neck and neck at over sixty miles an hour made horse racing seen quite tame, and this was the general opinion of thos present.

Victories of an English Machine.

“B.S.A. riders had a great day out. Woodma started off by winning the Light Weight Handica from scratch, with Karton, also on a B.S.A., second The same riders were first and second again in th Middle Weight Championship. In the big ope handicap, Bonnington rode a B.S.A., for the firs time, and just won from Woodman, who rode anothe great race on his B.S.A. In the Relay Race Woodman won the event for his team, beating his rival b over 600 yards. To cap all, two men were put o B.S.A.'s in the final Consolation Race, and score first and third. It was a great series of wins agains all the best riders of New Zealand, and the victories o Woodman, who has only one leg, and who has n rival as a daring and spectacular rider, were mos popular.”

Letters to the Editor

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

THE RULE OF THE ROAD AND OF THE FOOTPATH.

Sir,—May I make a suggestion concerning your recent remarks on the rule of the road? In towns and places with pavements, pedestrians are, or should be, more or less on the look out for traffic. On country roads the fact that vehicles keep to the left and pedestrians keep to the right is the greatest safeguard. G. N. PHILLIPS.

SIDECAR SPRINGING.

Sir,—I was greatly interested in the remarks in your Overseas Section on sidecar springing and would like to endorse every word of them.

I had a 1915 Matchless combination with sprung sidecar wheel, and never fully appreciated its worth until I started riding my present combination, which is an almost similar model minus the sidecar sprung wheel. Unfortunately, Messrs. Collier have stopped fitting the sprung wheel, the reason given being that it interferes with the steering.

I suppose I must give Messrs. Collier credit for more experience than I have had, but I can only say that I never noticed this defect in 7,000 miles riding with all sorts of loads and road conditions, and I should never have sold the 1915 mount had I known that I should not be able to get another spring wheel model. S. J. LAYGELL.

FRENCH ROADS.

Sir,—The fact that writers on motor matters usually disparage the French *pavé* roads has always been to me a source of mild astonishment. I refer, of course, to the roads well behind the line which are not subject to shell fire, but which have to carry an extraordinarily heavy traffic of transport lorries, etc. *Pavé* appears to wear remarkably well, and wears gradually, not going into pot-holes as do other roads. It is almost dustless, and, although in wet weather a certain caution has to be exercised when cornering at speed, it is not much worse than are the roads at home under similar conditions. Personally, I should be pleased to see our own road authorities laying down *pavé* roads at home. It might be interesting to hear your readers' opinions on this point. The roads in the shell zone are naturally bad, shell holes usually being filled in with a few sand bags covered with gravel. The most noticeable effect of the bad roads on a motor cycle is the alarming regularity with which one's back tyre bursts, especially if one's riding weight is fifteen stone. Butt-ended tubes are the worst offenders, and the way in which a new butt-ender will blow out at the butt after a few miles of riding is positively heart breaking.

By the way, I wonder if any of your readers have managed to make a good repair of a butt-ender. I have tried many times with a deplorable lack of success.

One often hears the remark: "Triumph? Yes, a good machine spoilt by its spring forks." Possibly the Triumph forks are a thought less comfortable than, say, the Brampton Biflex, but for control and stability in grease and at speed I have never found their equal.

Apropos of nothing, if I could catch the designer of the kick starter of a certain W.D. 3½ h.p. I would shoot him on sight; a more deplorably inefficient article I have never seen. Although an excellent machine in other respects, I would most positively affirm that its kick starter had been designed by the office boy. After the war, when petrol is obtainable again at a purely nominal charge, and I use my motor bicycle to carry me and my rod about the country in search of fresh waters to fish, Allah preserve me from the W.D. model. I shall certainly ride either a British flat twin or a Henderson "4." An unsprung single is, without a doubt, a vastly uncomfortable mount.

London. TAMPION.

SLEEVE ENGINE FOR MOTOR CYCLES.

Sir,—I am afraid all the claims made for sleeve valve engines in the car world are not borne out by facts. Anyone who has had hard practical experience with them realises this, especially as regards silence. I have seen very few out here that do not develop heartrending knocks after a few weeks' running. They do give good service as a whole, but I consider them capable of many improvements before they are quite perfect, even for a car, much less as fit for an air-cooled engine on a motor cycle.

B.E.F. MOTOR CYCLIST.

CRITICISM!

Sir,—I noted with some disgust that a contemporary has made a very feeble effort at wit, pointed, I presume, at one of the dainty little headings used in your journal.

I have often admired this heading, and beg to say that it was quite in season. Had the writer been more of a florist, or *his florist* more of a motor cyclist, their combined efforts would have held more truth.

I might suggest that the writer does not live in the only spot on the map where your paper is sold, and if he cares to visit Sheffield I can show him daffodils still in bud; in fact, a local well-known daffodil garden—where hundreds of pounds have been collected for charities—has not yet been opened for the annual show.

What about the gardens further north? J.G.

[Many thanks.—Ed.]

TWIST GRIP CONTROLS.

Sir,—May I say a few words about twist-grip control? On my Excelsior the controls are composed of substantial metal rods in full view, and, there being no wires to break, no attention, beyond a grease over, need be paid to them.

It is simplicity itself, and, personally, I am resolved not to revert to the old "tap-twiddling" operation. On the Excelsior, where the left grip controls the clutch, it is unnecessary to remove the hands from the bars for long distances, as I surmount main road hills with three up, and, of course, there is no need to refer to the advantages of this in traffic.

I also have heard it suggested that the grip was liable to turn under vibration of the bars. This is not so, as there is sufficient stiffness to resist this tendency.

There is another fallacy, to the effect that, as one cannot see the position of the levers, so to speak, it is impossible to tell how much gas one is giving. In this case, motorists who go by the *feel* of their engine can readily tell when changing from pilot to main jet and onward by the more powerful beat of the engine.

Again, American twist-grip controlled carburetters give that quiet, economical "tick-over" instead of the nerve racking roar of some British machines when in free engine, there being no need of careful tuning to obtain that much-sought-after asset.

Then there is the no-trouble mechanical pump lubrication—but "nuf sed"; this ground has been gone over so many times already. AMERICAN EX.

Watford.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—I notice in *The Motor Cycle* of April 11th and 18th that a few A.M.'s in the R.A.F. do not seem to like trade tests. No doubt they are not being treated fairly compared with the M.T.'s, but the whole war is unfair. An A.M.'s job looks all right compared with the infantryman's, though, you will admit, there must be thousands of motor men in the infantry who will come out whole if they are lucky.

Anyhow, I would like to see every man go through a good trade test to get into a unit such as the R.A.F., and go through a stiffer one to become a 1st A.M., and so on. Therefore I fail to see where the "cruel injustice" or the "grave insult to the motoring fraternity" comes in. One has only to look in the "Questions and Replies" column to see that a man does not become a mechanic just because he has owned a "grid" for some time. Anyhow, if a man knows anything at all about an internal combustion engine, he can pass the required "test." So why worry? A.F.C.

Canterbury.

Sir,—May we ask the favour of a few lines to reply to "A Few Non-technical Privates, R.A.F.," in your issue of April 18th? We air mechanics wish to contradict their statement *re* doing all their own repairs to their motor cycles.

May we point out that no driver of either a motor cycle or a car is under any circumstances allowed to do any "repairs" or "adjustments" on his machine whatever, as we, the M.T. fitters, are at all times responsible for the mechanical parts of all machines being in a serviceable condition? A FEW M.T. FITTERS, R.A.F.

Sir,—All motor cyclists of the R.F.C.—particularly Overseas men—feel very dissatisfied at being remustered under the new Air Force as non-technical. We wonder what our officer in command of transport would think or say were we really non-technical.

Half a dozen of us are stationed in this district, and although belonging to various units, each unit with its own C.O., we all possess the "prop" of the First Class Air Mechanic. Why have we received this distinction if it is not that we have proved efficient in our duties? It is surely agreed that to be a good motor cyclist one must have technical knowledge of one's 'bus. We were required to pass a test on enlisting in the corps. What for? Our fortunate brothers, the M.T. drivers, are themselves at a loss as to why the distinction is made.

After reading so frequently in yonr popular journal and in the daily papers of the grand, hard work done by D.R.'s (both R.E. and R.F.C.), the attitude taken by the "powers that be" towards the motor cyclist is distinctly unflattering and discouraging. SIX FIRST A.M.'S.

Newcastle.

Sir,—I am another motor cyclist who thinks the cyclists in the R.A.F. are being treated very unfairly, not so much in the title—viz., private—as in the rate of pay. The cyclist's job out here is by far the most treacherous work in the R.A.F., except, of course, the pilot's, and I consider our position should be put before those in authority, with a view to having it looked into and revised. This, I might say, is the opinion of all the motor cyclists out here, and also of one who wears

B.E.F. THREE BLUE 'UNS.

A PLEA FOR HIGHER GEARS.

Sir,—I support "Four Crazy" in his appeal for higher gears. A motor cycle with a 5 to 1 top and change-speed gear for solo work necessitates unnecessary engine revolutions to get over the ground, though for war service it is undoubtedly ideal. An article some years ago described an official run on a $3\frac{1}{2}$ h.p. Rover with Armstrong hub gear, "and the $3\frac{1}{2}$ to 1 gear was taken quite smoothly by the heavy flywheels." My 1913 Rover has a top gear of $3\frac{1}{2}$ to 1, middle $4\frac{3}{4}$ to 1, bottom gear about 7. If the bottom gear were 12 or 15 to 1, the combination of gears would be my ideal. The bottom gear—only wanted in an emergency—should be very low. When running on top, the smooth, slow pulling is not so tiring as a machine that is revving its heart out to maintain 30 m.p.h.

I should certainly like a run on a $2\frac{3}{4}$ h.p. single that can do fifty on the road. I should most likely leave it behind at 35-40—speedometers vary so much. Anyway, to cover a distance quickly without any fuss a high gear is a great help. An ideal machine would be a four-stroke 90°, four-cylinder, outside flywheel, which would pull a high gear. I have no interest in the Rover except as a satisfied user.

Leiston. V.A.B.

A BAFFLING EXPERIENCE.

Sir,—In reply to Mr. Chapman's letter in your issue of April 18th, with reference to his breakdown. Some time ago I had a similar trouble with my machine fitted with J.A.P. engine and E.I.C. magneto.

Having done the same as Mr. Chapman did without success, I removed the magneto cover, and there I found my trouble.

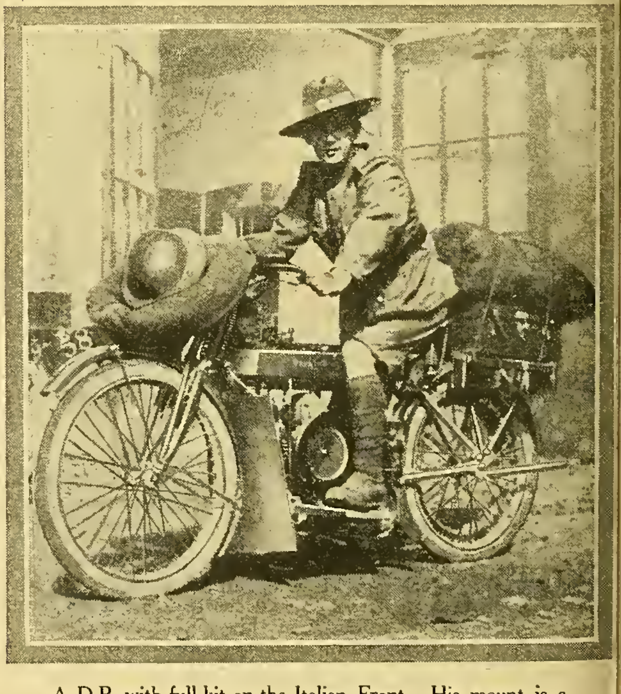
It was a damp day, and the dampness had made the fibre on the make and break swell. The result of this was that the rocker arm was working very stiffly, and at times jamming altogether, so that, instead of closing the points with a click, it closed them slowly, with the result that the spark occurred either extremely late or early.

Thus when I removed the plug it was sparking perfectly but not at anything like the right time, although the timing of the magneto was quite all right.

Therefore I should suggest that this was Mr. Chapman's trouble, and when the machine was left in a dry garage for a few hours the fibre dried, so that the rocker arm was performing its function correctly with the spark occurring at the right time. I hope this will prove of service to Mr. Chapman should the trouble occur again. L. MOON.

Sir,—I had a similar experience to Mr. F. W. Chapman as stated in your issue of April 18th. Recently, when preparing a $3\frac{1}{2}$ h.p. 1914 three-speed hub Triumph for the road, I got all in good order, but no explosions on trying kick start. This was a surprise, as I had carefully cleaned all parts thoroughly. I then took off the magneto cover; make and break seemed perfect. Tried again; no response. Tried wire; good shock. Tried testing spark at plug points; also good. Inserted plug again; still no response. Then I took off the outer mechanism of magneto, and found on the inner edge of one platinum point a small bit of fluff. Here was the cause of my trouble. I carefully cleaned all moving parts, reassembed the magneto, and got the engine firing first kick.

I may say that I have been a regular reader of *The Motor Cycle* since March, 1914, and have found it of great help in many tricky problems. T.D.



A D.R. with full kit on the Italian Front. His mount is a W.D. Douglas.

AN EXCELLENT SUGGESTION.

Sir,—Your paper has excelled itself recently. The articles on the "Outside Flywheel" and the "Case for the Long Stroke" and numerous others are worth reading again and again. Now I have never seen you deal with the contents of the timing case, except in isolated cases, and I should like to see the matter dealt with in your pages week by week. The dispositions of cams, rollers, and tappets make the timing mechanism noisy or quiet: let us observe how the problem is attacked by various makers.

I have taken the "Blue 'Un" since 1907, and still have it sent to me regularly. G. H. HAMILTON, Lt.

Italian E.F.

[Curiously enough, it happens that such an article is already in course of preparation.—Ed.]

AN UNEXPLAINED SPILL.

Sir,—It is greatly interesting to follow the various debates in your most valuable paper, and I may say that I have gained much information by them.

As a solo rider of moderate horse-power I have very little to relate, but an incident I witnessed recently would, I think, be of some value to those intending to be "sidecar" drivers.

While walking along the Southsea Promenade, a James and sidecar (fully laden) slowly passed by, and, as there was nothing unusual, no notice was taken of it. Then I heard a sudden rush of the engine, and, on turning round—my dismay can be imagined—there was the machine and sidecar absolutely turned turtle, with the engine racing and smoking. I rushed over and stopped the engine. The sidecar passenger was just extricating himself, and was rather badly bruised; the driver was also badly shaken. The most fortunate part was that when everything was straightened out, the only thing damaged was the sidecar lamp. This speaks highly for the 4¼ h.p. James.

It is rather a puzzler how this could have occurred, as the road was in very decent condition and no traffic or anything about at the time. I never realised that such an accident could occur with a sidecar, and I should be greatly obliged if any of your readers could explain the reason. D.F.

Portsmouth.

THE BEST GEAR FOR STARTING.

Sir,—I have just received my copy of the "Blue 'Un" for January 24th (January 3rd, 10th, and 17th miscarried), and I hope it is not too late to say how pleased I am to note the stand you have made regarding "Goods made in Germany." [This correspondence is closed, but we print the following letter as it comes from a distance.—Ed.] Hearty congratulations and strong blows to thine arm. How Mr. Ives and his so-called band of sportsmen can have the effrontery to make such statements in face of the devilish conduct of the enemy day by day I cannot understand. I only wish I could have the pleasure of conducting Mr. Ives over the battle area of "insignificant" Palestine. I could almost guarantee to change his tune before the close of the first day. If he and his followers have discontinued their patronage of the "Blue 'Un" (which I very much doubt), you may rest assured you are well rid of such pro-German piffle.

Now I shall be glad if you will permit me to air my humble opinion regarding your reply to "C.R.S." under "Questions and Replies." He had apparently been taught to start in low gear, while the garage proprietor and yourself advise the top gear. But what about the second gear as a happy medium? As the second gear is not mentioned by either of you, I should be very glad to know why, as there appears to be a reason for it. I have a 7-9 h.p. 1916 Indian, and have always started in the second gear, both with and without sidecar, unless I had more than one passenger, which is the only time I find it necessary to resort to low gear. This is the advice I had from Messrs. Godfrey, and it certainly appeals to the good behaviour of the engine, etc. My reason is this. If starting without the sidecar, it is usual, I think, for most riders to push off instead of using the kick start, in which case, unless the machine be pushed at a good running pace, a knocking must naturally be the result if the top gear is used. Moreover, should the throttle be partly open when the engine fires, it is very doubtful, unless one is semi-acrobatic, whether one will land decently in the saddle, or see the machine go down the road riderless. This danger is reduced to a minimum when the second gear is used: I am not a timid rider by any means, but I have always found the second gear lively enough, while the top is too high if one has any feeling for the engine. Even with the sidecar attached, I think the second gear is quite low enough to get away comfortably with the ordinary load, the low gear being used for a heavy load or a stiff hill.

I should very much like to hear the opinions of other riders on these points, as I can only remember one or two isolated cases where the average rider starts away on top.

Cairo. STANLEY F. KAY.

THE CASE FOR THE LONG STROKE.

Sir,—May I take the liberty of criticising some statements made in an article by Alex. Lindsay, M.B., in your issue of March 28th last? I hope your contributor will take these remarks in the spirit in which they are addressed. No advancement in mechanical science can ever be made without the ventilation of the arguments of both sides.

The author of the article in question states that the "longer induction effort of a long stroke engine results in a very easy start." This, to my mind, is fallacious. The volume of gas drawn into the cylinder is in no way affected by the proportion which the bore bears to the stroke. If a long stroke engine and a short stroke engine both possess the same cubic capacity, and if the design of the induction pipe and inlet port is equally good, then the amount of gas induced is the same in each case. This is a fundamental fact, and no statement to the contrary can alter it. A 79 × 100 T.T. Norton, an 85 × 88 T.T. Rudge, an 85 × 88 T.T. Triumph, and a 90 bore twin J.A.P.-engined machine which I used in 1914 all started with equal ease.

Dr. Lindsay indicates throughout his article that the long stroke engine is capable of pulling a higher gear under average circumstances than the ordinary square engine. This is a debatable point. A 3½ h.p. T.T. square-engined Rudge gave me entire satisfaction on any ordinary main roads with a fixed gear of 3½ to 1. A 3½ h.p. Premier used a gear of 3¾ to 1, and a 3½ h.p. T.T. Triumph travelled from Manchester to Gloucester and back using a gear of 3⅜ to 1, climbing all hills with ease. This latter may have been a freak performance, but it was actually accomplished. No long stroke engine of my acquaintance has ever bettered these ratios.

It is also stated that when running on benzole or other slow burning fuel the long stroke engine utilises the slower rate of flame propagation to the full. If both types of engine are running at the same speed, then in each case the piston is exposed to the push of the explosion for exactly the same length of time. The length of stroke has no bearing on this question. It is also claimed for the long stroke engine that the smaller diameter piston can be made much lighter than it can in the square engine. This is undoubtedly true, but it is counterbalanced by the fact that the piston has to be accelerated from rest to a much higher speed at the centre of its stroke than has the piston of the square engine, and in the same time.

The petrol consumption of any machine is largely a personal equation. The Rudge mentioned averaged 110 m.p.g. over 12,000 miles. Of five T.T. Nortons of my acquaintance four failed to reach 100 m.p.g. over long mileages, while the fifth averaged 104 m.p.g. A square engined Ivy-Precision at the same period averaged 108 m.p.g., and a 3½ h.p. Triumph 102 m.p.g. over long distances. Thus, the long stroke engine can claim no advantage in this respect.

When it comes to speed, then I bow, at the present time, to the splendid records gained by long stroke engines. But the Norton's 83 m.p.h. has been almost equalled by the short stroke A.B.C., and the difference between the two speeds is too small to quibble about. In the Senior T.T. race of 1913 a square engined Rudge was only beaten by five seconds, and that by a twin-cylinder two-stroke. In the Senior T.T. race of 1914 a square-engined Rudge defeated all its opponents with ease, including many long-stroke engines. This performance, over a gruelling course of over 200 miles, is infinitely better than covering a flying kilometre on a cement track with a freak machine and every artificial aid to speed that can be procured. N. S. BOWES.

B.E.F.

SUMMARY OF CORRESPONDENCE.

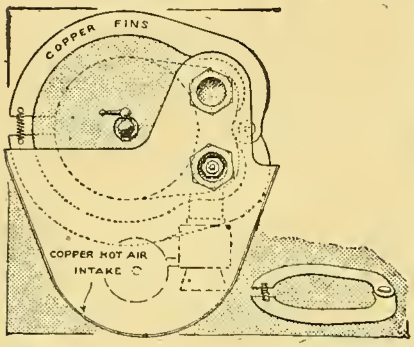
A BAFFLING EXPERIENCE.

In a letter on this subject the words "fibre brush" occur. "Brush" should, of course, read "bush."

Experiences with a 4 h.p. Wolf in India.

The Overheating Difficulty and its Treatment.

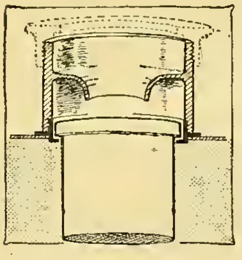
OVERHEATING of air-cooled engines often occurs in countries of temperate climate, and one can fully appreciate the difficulties motor cyclists have to contend with in such a country as India. From time to time we receive details of improvised methods of combating the overheating evil, and the following account received from Mr. Robert Brooks, of Howrah, Bengal, shows how successful his experiments were in this direction.



Plan view of combustion head, showing how the hot air intake or scoop is fitted on to the cylinders. (Inset) One of the hinged fins and hooked spring.

He says: "Some months ago I sent you a report of road tests of my machine—a 4 h.p. 1914 Wolf motor cycle with sidecar and passenger. I then obtained eighty-three miles to the gallon.

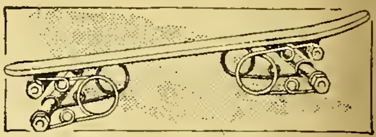
"I have since added radiating fins of copper to the cylinder, hinged between the valves, and clamped by hooked springs on the opposite side, and over this have fitted a hot air scoop held by valve caps on top and feed pipe connections below. This also acts as heating jacket round carburetter and float chamber. I recently filled up with one gallon of American kerosene called 'Tidewater-oil' for a solo test. The circuit I followed was about twenty-one miles in extent, one-third of this being in the suburbs of Calcutta and under the fifteen miles speed limit. After a five hours and forty minutes non-stop run, mileage then at one hundred and twenty, I was feeling dusty, tired, and hungry. On sounding the tank I found still a quantity of oil left; I then closed down for the day. Two days later I got twenty miles more from the same, making one hundred and forty miles in all. Feed pipe joints were not in the best of order: every connection showed a little leakage. The machine has not had proper attention; crank case and hubs have never been opened, and I am still using the original sparking plug, piston rings, valves and springs. The engine has been decarbonised about each fifteen hundred miles, and that is about all the pampering it has had. The carburetter is a Senspray, which I consider splendid for straight-away work.



The extension to filler cap, which effectively prevented waste of petrol.

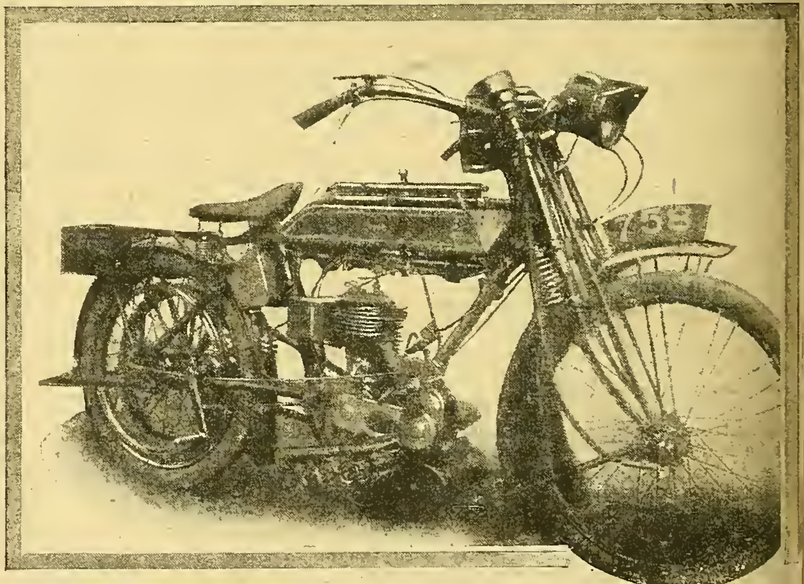
Detail Improvements.

"You will perhaps see by the photographs that I have made several additions. I have fitted a silencer chamber about three times the original size, and a one-inch tail pipe. A cut-out is fitted to act as an alarm while running through native bazaars, cattle, goats, etc., when sharp note is necessary to draw thei attention. Loop springs are fitted unde footboards, four under each, drip extensions to mudguards, and saddle pilla clip turned over reduces height of saddl one and a half inches. The petrol and oi filler caps were allowing a lot of waste so I carried them up one and a hal inches and followed the old idea of th unspillable ink pot, and now there is n loss from that quarter. Everything i still in splendid working order. I hav no interest in any of the parties named except as a satisfied user.



The springing arrangement of the footboards.

"As for my next machine—not that th change will be early—it will certainly b all-British."



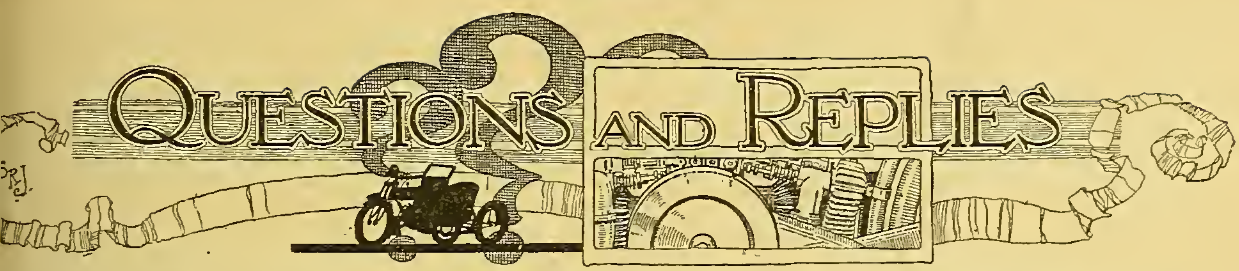
The 4 h.p. J.A.P.-engined Wolf, to which several refinements have been fitted, including spring footboards and special cooling arrangements.

* * *

COAL GAS AND MOTORISTS.

WE have more than once suggested that there is more in coal gas of interest to motorists than most of the latter are aware. Everyone knows, of course, that benzole depends for its existence in this country on the coal gas industry; but there is more than this in the question, as was recently revealed in the address given to the British Commercial Gas Association by the retiring president, Sir Robert Hadfield, F.R.S. According to a German scholar, the coal resources of this country will last for some 500 years, as compared with 1,000 years for those of Germany, and 600 for those of France. The remedy for the present extravagant method of using coal is its use not as a fuel directly but as a gas, and this use on a more extended scale will result, of course, in a great increase in the production of by-products, one of which is an excellent motor fuel.

Sir Robert then dealt with other possible sources of fuel for motor vehicles. And it is of real interest to see that man of such authority agrees with that the most likely solution of fut difficulties lies in the adoption of alcol as a motor fuel. In conjunction w Prof. Burstall, another eminent authori Sir Robert thinks that the cactus pl of Australia contains the most promisi germs of a final solution, because plant has the requisite chemical featur and, moreover, is exceedingly luxuri in growth.



QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle,"
Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents
urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal
estions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Belt Line Trouble.

I am the possessor and driver of a 1912 free engine Triumph. Last July, whilst on a journey of twenty miles, the belt from the pulley to the belt drum ran very
egularly, and twisted and turned,
ipping and spoiling the belt. I
ight a new one, and ran it all
ht till the second week in April,
en it did similar antics. I took the
chine to a garage, and closed the
ley so that the belt was about
eequarters of the way up the
ley; it is just level in the belt
im. If I get up to 20 m.p.h. the
ip of the belt throws it off the
t drum. The pulley and belt drum
pear to be in a line, and I am at a
s to know what to do.—W.J.B.

trouble cannot lie in the belt itself,
must be a fault of alignment of the
ys, even although you think these
correct. Possibly they are correct
the machine is stationary, but
may be play in the belt rim, or the
e itself may be loose in the frame,
at when the strain on the belt is
ased the belt-line is upset. If this
e trouble, it could quite easily be
mittent.

Removing a Pulley.

I am overhauling my 1914 Zenith-Jap (1913 pattern). I want to remove the flange of the Gradua pulley from the crankshaft; will you kindly suggest
best method? I have tried
dging it all round and also levering
but it seems to have got very tight.
ave removed the pulleys from other
kes of machines, but have not ex-
ienced such a tight fit. As it is
own machine, of course I am
ious not to damage the crank case.
hough I am a motor cycle artificer,
m always on the look-out for better
thods of procedure.—R.C.C.

best plan will be for you to use a
r pulley drawer, which can be
ned from most accessory dealers,
as Markt and Co., Ltd., 98-100,
enwell Road, London, E.C.1;
n Bros., Ltd., 15, Newman Street,
on, W.1. etc. Tapping sharply on
op of the flange sometimes loosens
fficiently for it to be withdrawn.
this is not a good method, and if
have found that wedges fail and
cannot obtain the use of a pulley
er, we should recommend you to
the crank case to Messrs. Zenith
rs, Ltd., Hampton Court, Middle-
who will remove the flange and
n it to you the same day.

Hub Gear Maker's Address.

Would you be kind enough to give me the address, if possible, of the Armstrong hub gear manufacturers?—H.T.

The Armstrong Three-speed Gear Co. is not now in existence, but a letter addressed to Messrs. Sturmey-Archer Gears, Ltd., Beeston, Nottingham, would secure an answer to any enquiries you may wish to make regarding the Armstrong gear.

Please give your order for 'The Motor Cycle' TO-DAY.

This is necessary, both in the interests of national economy and to ensure getting copies regularly.

¶ It is impossible to lay too much stress on the importance of economy in the consumption of paper. Supplies are restricted to such a degree that only by conserving the stocks can publishers continue to meet the requirements of regular readers. The shortage is now too serious for the usual provision to be made for chance sales; the risk of copies remaining unsold must be eliminated.

¶ Every unsold copy represents waste, and to prevent waste in this direction each reader should take the simple step of asking a newsagent or bookstall clerk to reserve or deliver a copy weekly. This will help the newsagents and the publishers to regulate the supply according to the actual demand and to fulfil their orders without undue risk of copies being wasted.

How to find the Horse-power.

I have made several enquiries of supposed experienced men on the question of how to find the h.p. of an internal combustion engine, and none has been satisfactory. Would you please supply the necessary information?—H.B.

There are several ways of finding out the horse-power of an internal combustion engine. The only accurate way, however, is by means of a proper brake test—by measuring the power developed at the engine pulley by applying the brake to that portion of the engine, by calculating the pull in lb. and reading the revolutions per minute on a tachometer, or electrically, in which case the number of units of electricity developed by the engine are equivalent to so many horse-power. As regards formulæ, perhaps the most satisfactory is Hospitalier's, which is as follows: Square the radius of the piston in centimetres, multiply by the stroke in centimetres, multiply by the number of revolutions per minute, divide by 1,000, and again by 75. ·75 kilogram-metres per sec. equal 1 h.p.

Carburation and Air Leak.

I should be much obliged if you would kindly give me information on the following points: (1.) I have fitted a new carburetter to my 6 h.p. Clyno motor cycle, and find that the float chamber touches the rear cylinder and will consequently get very hot. I should be glad to know if there is any fear of fire; and, if not, will this assist carburation? (2.) How would you adjust 1915 Clyno tappets which have not the usual adjusting nuts fitted? (3.) Will you please tell me the best method of stopping air leak at the induction pipe unions?—R.H.M.

(1.) There should be no risk of fire, provided the liquid petrol does not come into actual contact with the exhaust pipe. The cylinder is not likely to become hot enough to ignite the petrol. The effect on carburation is theoretically beneficial, but practically negligible. (2.) You may obtain a set of tappet adjusters from any of the large accessory houses. These are small fitments specially designed for engines that are not provided with adjustable tappets. (3.) The best method is to screw up all joints carefully, but if this proves to be ineffective, the usual remedy is to wrap the joints round most carefully with insulating tape. While it is never as neat as the joint made in the correct manner, it is very often employed.

Removing the Small Timing Pinion.

?

Could you please tell me how the small timing gear pinion on the engine-shaft of my 4 h.p. Bradbury is fastened? Is it screwed on with a left or right-hand thread, with a screw let in the centre of the shaft to expand it after the pinion is screwed home?—W.C.

The timing pinion is fastened by means of a conical-headed screw expanding a split engine-shaft, which carries the pinion round by means of a key. All you have to do, therefore, is to remove the screw and lever off the pinion.

Decarbonisation.

?

(1.) What is the best and most successful method of removing carbon deposit from the cylinder head? (2.) Is it an indication of faulty piston rings when a portion of the piston is black and not bright like the other portion of it, and will the result be "loss of compression"? (3.) Down the side of my magneto, on the outside, are the letters "BDHLER." Do these letters indicate the maker's name, and if so, what is it?—Amateur.

(1.) Remove the cylinder and scrape with a screwdriver, blunt chisel, or other suitable scraper. (2.) Yes, the black mark shows that the charge is leaking past the piston rings, and will cause loss of compression. It is caused by faulty rings. (3.) We regret to say we do not know the magneto. It looks as if the letters mentioned refer to the maker's name.

Charging Accumulators by a Magneto.

?

I have a small old type single-cylinder Simms magneto. Is it possible to convert it into a generator for charging a small accumulator for lighting purposes and not use it as a magneto, or is a magneto not suitable for anything else but for a sparking plug? It is only for hobby work that I require it.—H.A.E.

There is no reason whatever why an old magneto should not be quite successfully converted into a small generator suitable for battery charging and lighting, but it will be necessary to take out the armature, rewind it, and fit a commutator. This is by no means too difficult for anyone accustomed to using a few tools, and with a mechanical turn of mind. The reason for fitting a commutator is that the current from a magneto is naturally alternating, and would not do for accumulator charging. The commutator, however, need only be a simple two-part affair. Before removing the armature a piece of iron must be laid across the poles of the field magnets, and must remain there until the armature is replaced; otherwise the magnetism may be lost. As the magnet in question is an old one, and may have been lying about for some time, it would be as well, while the armature is being rewound, to have the magnets remagnetised. Full information on making small dynamos such as this will be found in a sixpenny book called "Small Dynamos and Motors," published by Messrs. Percival Marshall and Co., being No. 10 of the *Model Engineer* series of handbooks.

Tube Bending.

?

Would you please tell me the best way of bending the handle-bars of my 2¾ h.p. T.T. Douglas? I wish to bend them outwards and downwards, as I do not like them as they are at present. Could it be done satisfactorily by means of a Bunsen burner?—J.B.

The handle-bar could be bent by means of a Bunsen burner, if the latter were held under the place you wish to bend, but the bending of tubes requires a certain amount of skill. To avoid kinking the tube should be tightly filled with sand, but very much depends upon the acuteness of the bend desired. Unless you are experienced, you would be better advised to take the job to a competent repairer.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

Engine will not Start.

?

Would you kindly suggest the probable cause of the trouble with my 2¾ h.p. Calthorpe-Jap? I cannot get it even to fire. I have checked the magneto and valve timing and seen that the petrol gets into the cylinder all right.—R.B.B.

The trouble may be due to a defect in the magneto, and you do not state if it is sparking properly; or to air leaks at the carburetter or induction pipe unions, which would prevent the engine from starting.

A Soldier's Permit.

?

I wish to ask you if I can take my brother (a convalescent soldier) out for an airing in my sidecar. I have the petrol by me from last year's permit; and as I have not seen anything in your paper lately on this question, I want to be on the safe side. I have taken out my driving licence and local taxation licence for this purpose. I should also like to ask your advice and opinion on a plug I had from a friend. Instead of the ordinary porcelain, it is made of transparent material like quartz, and when the engine is running it is illuminated like a powerful electric light.—J.W.

If your brother is convalescent after service Overseas, you will be able to take him out in the sidecar, provided he applies to the Petrol Controller's Department, 19, Berkeley Street, London, W.1, for a permit to use the machine, giving its registered number. The plug is probably a quartz plug, designed so as to show the colour of the explosion in the combustion chamber, thus indicating the quality of the mixture and showing whether it is correct or not. There is no reason why you should not use it.

READERS' REPLIES.

Low-tension Magnetos.

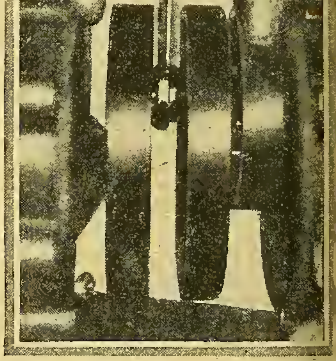
In the "Questions and Replies" s tion of your issue for April 18th, y correspondent "C.L.D." asks for book on low-tension magnetos. I hav 1911 handbook containing a section wh deals with low-tension magnetos, should be pleased to let him have if he will send his address along A. C. Nevin.

Mysterious Two-stroke Trouble.

As the owner of a two-stroke cycle have been troubled with the same d culty as your correspondent. My exp ence was identical in every respect. getting the machine thoroughly examir I was informed that the magneto the cause of the trouble, there bein slight wear or rub of the fabric surrou ing the coil wire at one place, wh would probably cause a short circ The magneto having been exchanged, trouble has disappeared.—E.A.S.

Truing Up Flywheels.

I send you a photograph of the met I employed to true up the flywheels my A.J.S. motor cycle. After a gla at the photograph the idea does not r much explanation. The two halves of crank case are lightly secured to bench and the flywheels revolved. It then be seen if they run truly or adjustment.—David B. Bright.



A method of truing up flywheels.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

Military Motor Cycles.

THE introduction of the American standard motor cycle engine raises the important question whether for Army purposes it is better to use one type of motor cycle or several. The British D.R.'s (R.E. Signals) use two makes, Triumph and Douglas, the nominal h.p.'s being 4 and 2¾, and the capacities 550 and 350 c.c. The former is provided with a handle-bar controlled clutch—a very real advantage—and a three-speed gear, while in the case of the latter the Government has preferred to retain the pre-war model, which incorporated a two-speed gear only. Both these machines have done excellent work and both have their admirers. The more powerful machine is naturally the greater favourite, owing to its greater speed and power to plough through very heavy mud, but there are many occasions when the lighter weight of the Douglas gives it a great advantage, and renders it pleasanter and safer to ride. Some D.R.'s would vote for the Triumph in the summer and the Douglas in the winter time.

Then, again, we find that the R.F.C. have always favoured the P. and M., and many of these machines, with sidecars attached and lady drivers in the seats, are to be seen carrying Flying Corps officers from place to place with the most unfailing regularity. In Africa and elsewhere the B.S.A. has rendered a good account of itself, and more than one twin-cylinder machine, notably the Clyno and Enfield, has been fitted with machine guns or used for ambulance purposes.

Time will show whether the American standard engine can take the place of all these various types. Opinions differ, although the big American twin is tractable as well as powerful, and the clutch will doubtless be a good one. It ought to be able to plough its way at a slow pace through the deepest of mud without becoming unduly hot. (The small British machine was at a disadvantage here, though in many ways it excelled as a bad weather mount.) It has power and speed even when fitted up with a sidecar. But many occasions must of necessity arise when the riders will wish themselves the possessors of lighter and handier mounts. Power is wanted at all times and still more extreme reliability, but sometimes handiness will be more valuable than power.

When we consider the question of spare parts and replacements, it must at once be admitted that the standard machine has the advantage all the time. There is no need to labour the point—it is too obvious—but using a 1,000 c.c. engine for all purposes must sometimes be like using a steam hammer to crack a nut; it will do it excellently and without crushing the kernel, but it can be done more cheaply and expeditiously in other ways.

British experience suggests that variety is, on the whole, desirable, for conditions vary very materially on the different fronts and at different times of the year.

A Point of Design.

Quite outside the military question, the American standard army motor cycle engine is a most interesting production in that it represents the combined effort of the best brains employed in the American motor cycle trade. Any innovation or point of design found in it should therefore be treated with respect and carefully considered by British manufacturers, for it may be assumed that it has the reasoned approval of competent men, and is not introduced simply as a talking point. To take one detail alone as an example, the fact that mechanical lubrication has been adopted should make our own designers very careful how they allow themselves to be satisfied with the retention of the hand pump as a means of lubricating their post-war engines. The hand pump certainly works, and, in the hands of a capable rider, works well, but that the method is crude cannot be denied.

An index to the advertisements in this issue will be found on the page facing the back cover.

CONCRETE ROADS AFTER THE WAR?

Will Concrete Highways eventually Supersede Tarmac?

In these days concrete is used in almost every branch of engineering. For many years we have had concrete buildings. Last year concrete played a leading part in the German defensive, and this year it is being used extensively in the Allies' shipbuilding programme. A few years ago concrete ships would have been laughed to scorn by our builders of steel and wooden vessels, but, owing to rapidity of working and durability, concrete is being recognised as a material offering great possibilities in many spheres where its use was hitherto considered impossible.

Concrete as a road-making material has been used extensively in America. both in the United States and Canada, while in Great Britain its advantages were only just being recognised when the war put a stop to road-making on a large scale. Notwithstanding, there are several stretches of road in this country constructed by enterprising county boroughs and municipalities, and the very hard service to which they have been subjected under war conditions no doubt will serve to provide valuable data for post-war development.

A Question of Engineering.

Probably it will be found that some such experiments have not justified their engineers' highest hopes, but it is claimed that where such roads have not proved satisfactory it is due to the method of laying, as the making of a concrete road is more a question of engineering than the older methods of macadamising and "darning" in vogue in this country.

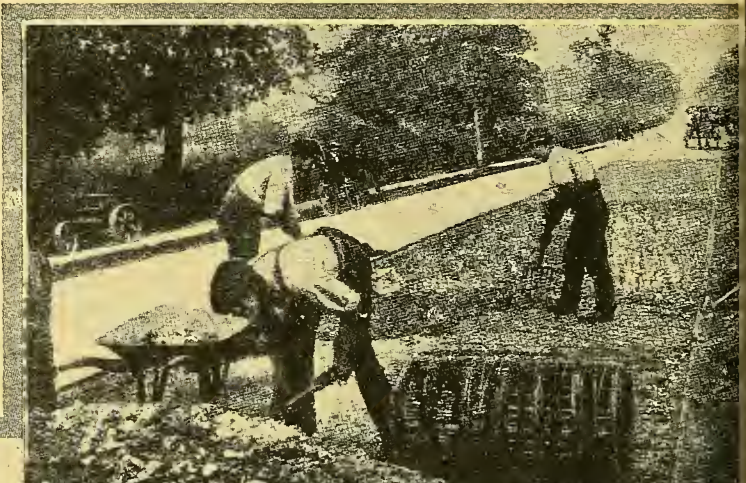
Undoubtedly roads with a smooth, unbroken surface form a matter of special interest to the motorist, and certain it is the roads which were quite satisfactory a decade ago will no longer serve the needs of the nation in the future. Therefore, if concrete roads are all that is claimed for them. it is to be hoped that scientifically constructed highways of this mate will be the rule rather than the exception in a years' time.

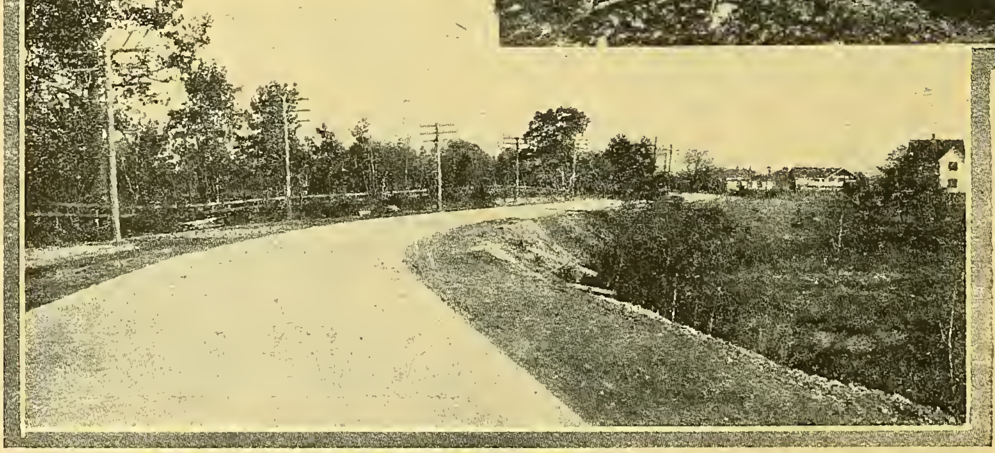
In America there are many hundreds of miles such roads, and, although subjected to climatic co tions that are not experienced in this country, are said to have proved highly satisfactory in e way for the traffic that has been run over them.

An Experiment in England.

A short time ago Redhill Road, Reigate, was built of reinforced concrete, and no doubt a re from the County Surveyor (A. Dryland, E M.I.C.E.) would be of great interest to motor The methods employed in building this road inclu the laying of a wire netting with the concrete, wh it is claimed, provides a perfect road foundation, spreads each wheel load over a very large area of under bed.

If we remember correctly, experiences with conc roads in other parts of this country have been encouraging, and should the great national highw which we are told (ex America) are to be built w the war is over, fructify, then concrete may be i for their surface.





(Top) Making a cc crete road. Strong w netting is laid in t foundation concrete.

(Bottom) A stretch concrete road America. Both U.S.A. and Canada cc crete is used extensiv in road construction.

Occasional Comments by "Ixion"

"Technical" Jobs.

F the Army intends now or in the future to enlist as D.R. privates men whose sole qualification is that they can ride a motor bicycle, it is absurd rank such ratings as "technical"; and it is common nowledge that the Service has been compelled to ain hurriedly tinkers, tailors, butchers, and bakers become "engineers in six weeks." It is absurd describe such a man as "technical"; if increasing xperience at last converts him into a pukka mechanic, e will presumably gain promotion; during the interim, is "technical" ability is imparted to him by the chool N.C.O.'s, and hardly affords a claim for extra emuneration. Many of these "army-learnt" men re only efficient so long as N.C.O.'s and officers are t hand to shepherd their efforts. Presumably the rievance now existing between "technical" lorry rivers and "non-technical" motor cyclists in the .A.F. arises from an intention to demand a far higher nechanical standard from M.T. drivers in years to ome than will be required of D.R.'s; and this policy s extremely sound. To take a single point, a lorry osts hundreds of pounds, a bicycle costs about £50. By the D.R. reasoning, a subaltern might claim the ame pay as a lieutenant-colonel; whereas the correct rinciple is that pay should be in proportion to responsibility.

How the Grievance Arises.

THE existing friction arises because the Army, like the law, does not legislate for hard cases. The simple and obvious fact is that many D.R.'s re skilled engineers, capable not only of riding a notor bicycle, but of overhauling it: possibly equal o constructing a machine, or even to designing it. The same applies to some of the M.T. drivers. But he evident R.A.F. policy is that, when things settle lown, the D.R. shall be a rider, pure and simple, whereas the M.T. man shall be an engineer. This deal has not yet developed in practice. Engineer D.R.'s find themselves rated lower and paid less than M.T. men whose motoring was limited to a penny icket on a Tilling 'bus less than six weeks ago. Hence hese tears. On the top of these anomalies, the Service suffers from a quite natural inflexibility. It is ull of "dead ends" and blind alleys. A man, gnorant of Army ways, enlists as a D.R. He turns out to be an all-round engineer, and quite exceptionally useful. The officers immediately over him value him, and do everything they can to keep him. Promotion loes not come his way, because the ranks just over his head are full, and chance to remain so. So he stays a "non-technical private," and has the mortification of seeing a rabbit trapper from his native village leveloped from this unmechanical basis into a full-blown "technical" M.T. man in six weeks, rated above himself, and paid more.

The Remedy.

I CONFESS that I cannot criticise the principle underlying the organisation. The M.T. man has more complex duties and heavier responsibilities. The M.T. men should be drawn from the more highly skilled ranks, should be given a more thorough training, and should receive more pay. Inefficiency on their part costs the nation pounds where a stupid D.R. costs the nation pennies. There is no need to quarrel about names, and even if it is a blunder to use the term "technical" somewhat arbitrarily in the mustering list, that is a mere detail. The kernel of the trouble is that it is possible for the more skilled men to be mustered for the less skilled job, and to get stuck in it. Organisation can hardly cure this. If it were open to the D.R. to submit himself for an examination as M.T. man, the case would not be mended, since a first-class motor cyclist may be hopelessly ignorant of three ton lorries; many Brooklands experts cut foolish figures the first time they tackle a Leyland. The remedy surely lies in the hands of the officers. It is an officer's business to know his men, and to promote the efficiency of his unit. I submit that the following points express the situation with tolerable justice:

(1.) In principle, lorry and car men should be rated and paid more highly than motor cyclists.

(2.) Injustices must occasionally occur.

(3.) The R.A.F. is a new force, and its organisation cannot be perfected in two months.

(4.) It is up to N.C.O.'s and subalterns not to waste good men on simple jobs.

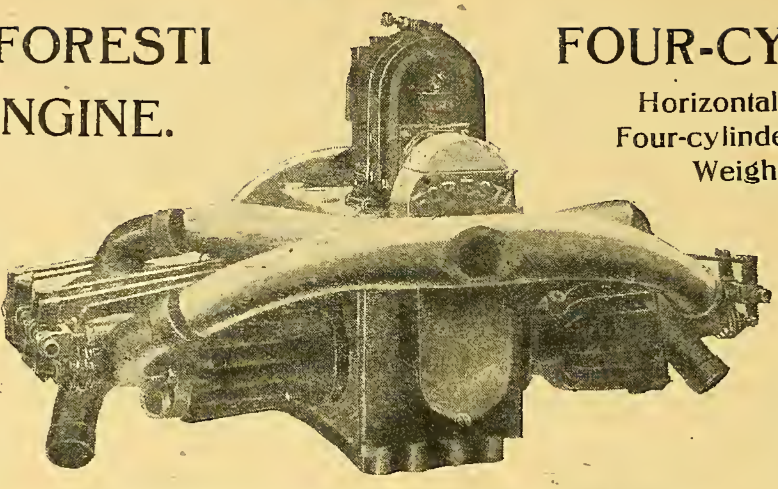
(5.) We shall all continue to do our bit to the best of our ability, even when the emergency machinery of war does not do us full personal justice.

M.T. and D.R. at the Front.

GENERALISATIONS are always perilous, and many people die without ever having grasped the difference between the average and the extreme. So I ought to guard the above reasoning from an attack which some reader is sure to make. It is by no means true that *every* M.T. man has a more responsible job than *every* D.R. For example, I know an M.T. private who is transporting fodder in Wales, and, *per contra,* I know a D.R. who practically saved a battalion by getting a message through under great difficulties and dangers in Fritz's push for Amiens. We must compare like with like. There is probably a D.R. toting round chits in Wales—match him with the fodder lorry. There is an M.T. man feeding the front guns before Amiens—match him with the Triumph under shell fire, and so on. Given the same conditions of service, the difference between the D.R. and the M.T. is parallel to the difference between a second lieutenant and a captain; in each case the latter bears the heavier responsibility.

THE FORESTI FOUR-CYLINDER FLAT ENGINE.

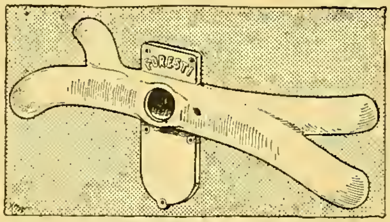
Horizontally-opposed, Four-cylinder, 700 c.c. Weight 60 lb.



The Foresti engine (700 c.c.), carburetter side, showing the neat design of the induction pipe casting.

THERE are few designers of motor cycle engines who are better qualified to turn out something possessing great originality, super-efficiency, and light weight than Signor Giulio Foresti, the dashing driver who created a great sensation in the 1913 Grand Prix on Moriando's Itala—a feat which was witnessed by a large number of motor cyclists, whose race meeting took place the following day. Foresti's car was upset just opposite the grandstand at Amiens, and by the herculean efforts of himself and his mechanic it was righted again and driven for thirteen more laps before the frame gave way.

So much for his prowess as a driver. The fact that for some years he was works manager of the Itala Works at Weybridge speaks for his qualifications as an engineer. Signor Foresti is not only an expert motor car driver, but also a keen motor cyclist, and his exceptional experience has resulted in his designing a most interesting engine. All the way through the designer has aimed at obtaining super-efficiency, and up to the present his efforts have been rewarded with no mean degree of success.

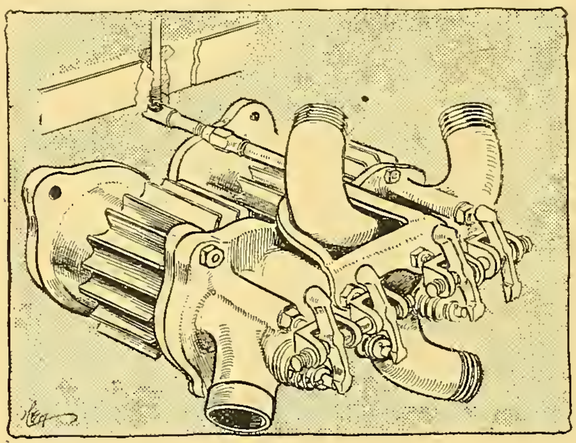


The Foresti induction pipe.

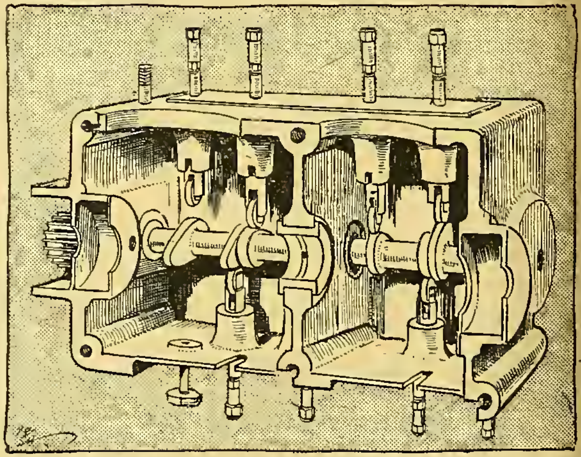
The little engine, which is a four-cylinder of the horizontally-opposed pattern, has a bore and stroke of 60 mm. × 61 mm., 700 c.c., and has developed on the bench 21 h.p., though in the ordinary course of events it would b rated at abou 6 h.p. The cylinders are provide with overhead valve situated in detachable heads, and als with horizontal cooling fins. The valve have hollow heads and are consequentl exceptionally light while the materia of which the rocke arms are made is very light steel. Considerabl ingenuity has been displayed in the method of fixin the cylinder by means of two studs and a specia fastener on one side of the crank case. This metho is shown in the accompanying sketch. It consists o a bridge clamping over the two cylinders from whicl an anchor rod runs. The lower end of this rod passe into a recess in the crank case, and one of the bolt holding the two crank case halve together passes through it. By thi means there is no chance of the bol coming adrift, as might be the cas if it were screwed straight into the aluminium. This fastening rod i provided with a long nut which ha a right and left-hand thread.

Lubrication.

The lubrication is effected b means of a vacuum pump, which keeps oil to the level of a quarter of an inch in the crank case, thence the lubrication is by splash, there being baffles to the rear cylinders so as to prevent these from receiving a excess of oil.



The method of bolting the cylinder to the crank case



The ball bearing camshaft and roller tappets of the Foresti engine.

T Foresti Four-cylinder Flat Twin.—

Some idea of the care taken to render the engine light as possible is shown by the clever way in ıich the connecting rod has been lightened, also e pistons are drilled with this end in view. The ston possesses two very light rings in the same oove, and is webbed inside so as to ensure its having nple strength.

The gudgeon pin is secured by two copper disc ngs, one each side—a very simple fitting which ccessfully anchors the gudgeon pin and prevents e possibility of any damage to the cylinder.

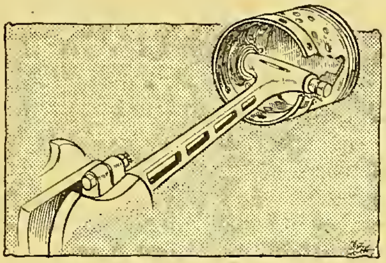
Split big ends are fitted, and the shes are of phosphor bronze, while imms are provided so that any ar in the bearings may be easily ken up. Suitable grooves with ssages are cut in both big and tle end bearings to ensure their ceiving plenty of lubricant.

An examination of the crankshaft veals the fact that it is of a simple ture and a remarkably well-made ece of work. It is of the four-row pattern, and is supported on o-double-ball bearings at each d and on a phosphor bronze bearg in the centre. The ball bearings e situated in recesses cast in the ank case. Another interesting ature in the crankshaft is that the lance weights are integral with the shaft itself, and e whole is made of one solid piece of steel, following test practice.

Cam Design.

The timing gear wheels are of very large size, so at they are entirely silent and of ample strength. he camshaft is placed immediately above the crankaft, and, like the latter, runs on ball bearings.

Signor Foresti's racing experience has been of great lue to him in the design of the cams, which follow cing car practice. The tappet rods are provided th rollers running on the cams, thus obviating ar and side thrust. The tappets are naturally of e adjustable pattern and work in phosphor bronze shes.



The Foresti piston and connecting rod. Note the manner in which both are lightened without interfering with their strength, the slot with two holes in the little end to ensure adequate lubrication of the gudgeon pins, the copper discs which hold in the gudgeon pin and the split pins of the big end bolts that prevent the nuts from moving.

One of our sketches shows the design of the induction pipe, which is part of the casting forming the cover of the timing gear case, and the particular form of induction pipe employed ensures a free passage for the gases, so that they are in no way baffled.

The care exercised in the design of this engine is demonstrated by the fact that a V piece is situated opposite the orifice leading from the carburetter, so that the mixture will be properly conducted to the various cylinders. The situation of the inlet pipe close up against the engine ensures its being always warm, and this should be of great assistance so far as carburation is concerned.

The magneto is fixed on the top of the timing gear case in such a position that it is quite accessible and may be easily detached.

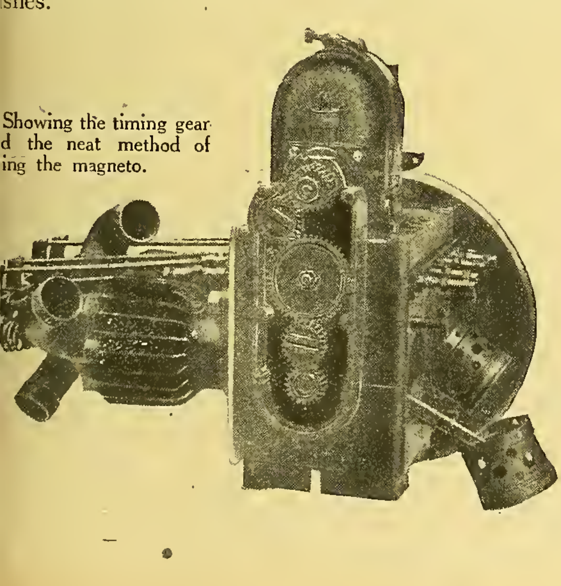
Absence of Vibration.

Another instance of the care exercised in the manufacture of this engine is the fact that a cap is screwed over the end of the flywheel bearing boss so as to make certain that the crank case is firmly secured at this point. It also ensures that the bearings are adequately protected.

It is only natural to find that an engine of this design is beautifully balanced, and, of course, vibration is practically absent, no matter at what speed the engine runs.

After experimenting with numerous carburetters, Signor Foresti found that the greatest satisfaction was obtained from an old C.A.P., which was the prototype of the modern B.S.A. carburetter.

At the time of our visit the engine had been dismantled, but it has actually run and given great satisfaction. Though at the present time it has not been fitted into a motor cycle, when the opportunity for fixing it in a frame comes we understand that it will be fitted up very much in the same manner as is the Douglas engine in its neat and well-known cradle.



Showing the timing gear

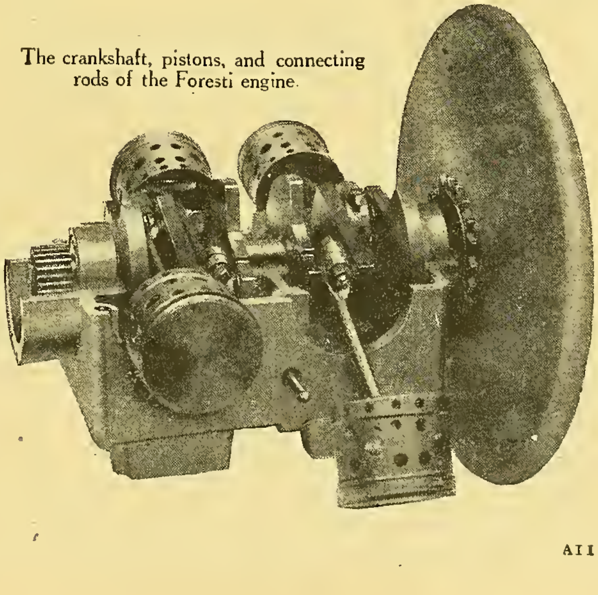
ing the magneto.



The crankshaft, pistons, and connecting rods of the Foresti engine.

SEATS OR SADDLES FOR SOLO MOUNTS?

A Reply to "Comfort in Riding" from a Rider of Much Experience.

As an old motor cyclist who has ridden machines fitted with all kinds of saddles and seats, including Brooks's bucket seat and the XL'All saddle seat, also saddles fitted with back rests, I may perhaps be allowed to say a few words on the subject of comfort, and what I consider more important, perhaps, even than comfort, viz., the safe riding and control of a motor bicycle.

Quite early in my motor cycling days, when spring forks, let alone spring frames, were practically non-existent, the makers supplied an ordinary cycle saddle with a slightly larger top, Brooks's B90 being a favoured model. Small hard blown tyres, rigid front forks, poorly balanced engines, etc., produced a considerable amount of fatigue in long-distance riding, the spinal cord being particularly affected if speed were indulged in over long distances. One of the first introductions for the rider's comfort was the back rest as in the illustration on page 406 of the issue of April 25th. This proved comparatively dangerous, because without a clutch to enable the machine to be started from rest with engine running, it was an acrobatic feat to land in the saddle by means of the running mount and to clear the back rest in doing it. The rider's position also did not enable the back rest to come into full play, for the simple reason that riders did not lean back, neither did they sit absolutely upright.

Back-supporting Straps.

I think I am right in saying that after the back rest came one or two back-supporting devices made of straps or webbing; these passed round the rider's waist and were hooked to a staple or other attachment on the top tube of the frame close to the top ball head lug. These attachments did add to the comfort of the rider, because they supported the spine in a better way than the fixed rest on the saddle cantle. The webbing or strapping did not dig into the back like the hard padding of the back rest. The drawback was that the rider was connected to the machine by a hook arrangement which was alleged to uncouple itself automatically in the event of an accident, and few cared to experiment with falls to ascertain if the device functioned correctly; these attachments were also very much in the way when dismounting and mounting, and they never became popular.

Bucket Seats.

Then came the bucket seats and the anatomical seats like the XL'All. To the best of my recollection experiments were first made by amateurs, the first I saw being made by a well-known Midland mot cyclist, who was fond of providing his machine wi other home-made appurtenances, such as tool boxe special mudguards, etc., and who very much preferr a bucket type of seat to a saddle. I remember ve well the first time I tried his machine so fitted aft coming straight from an ordinary Brooks bicyc saddle with coil springs—not the type now sold wi compensating springs and a broad seat, but a narro pedal bicycle saddle. I had been accustomed to gr the tank of the machine with my knees in the san way as a horseman grips the horse, and I found th although the bucket seat was very comfortable on roa which had shaken me about considerably when usi an ordinary saddle, the absence of the gripping contr made my position very insecure, and the first corn showed me that there was a great deal of differen between sitting nearly upright on a bucket seat ar leaning over with the tank knee grip to take corne on a single track machine.

Seats on Sidecar Outfits.

Soon after that I became possessed of a sideca and had an opportunity of trying the XL'All sadd seat. It was with some doubt as to its suitabili for motor cycle work that I fitted it, but I soon foun that the seat position on a motor cycle with sideca was a different proposition from the seat postu on a solo machine. The reduced speed and the fa that when turning corners one could not lean th bicycle over to right or left, meant that there was n longer that necessity to use the knees as a grip on th tank. With a sidecar, one can assume a more or les natural sitting position, but even with a sidecar ther is a considerable amount of roll, which to some rider makes a seat less attractive than a saddle. One als gets bumped about more, for reasons which I wil explain later.

In designing the XL'All anatomical seat, I thin the makers have endeavoured to embody the comfor of a seat with a certain amount of narrowness at th peak, which enables the grip control to be exercise within a limited degree. There is, of course, a goo deal claimed for the superior springing mechanism o this and one or two other saddle seats, but in thi article I only propose to deal with the seating position Personally, I do not think that the seat position wil ever be a success on a motor bicycle as apart fron the motor cycle and sidecar, and this is not on accoun of any inherent fault in the seat *per se* or because o the lack of control with a seat, but because the sea position destroys the flexing of the limbs by which natural springing action is obtained.

Where the side-car scores

In these days, when we cannot do as we did in days of yore—when petrol as a power-producer is restricted to use for National requirements—

Many of us dream of "things to be"—

We have all sorts of ideas as to the future—we dream of high-powered Cars—of Aeroplanes—and of wonderful performances by Land, by Air, by Sea, but—

In the future we shall "come to Earth" again, and find in common agreement that the Sidecar Combination as a means of travel "scores" at every point and has no superior.

We are not "dreaming" when we tell you so, as we do in an interesting little folder called "The Post-War Clyno"—a folder which also gives you fullest details of our "after-war" machine—the 8 h.p. model, and tells all about our policy of MASS PRODUCTION OF ONE MODEL, and our scheme of ROTATIONAL DELIVERY of THE Sidecar Motor Cycle—the

ats or Saddles for Solo Mounts ?

The natural seated position is one in which the ighs are practically horizontal. Let the reader sit n a chair with feet extended forward and resting on ıe floor and hold on to some object such as a chair ack situated the same distance from the seat as the pace between the saddle and a handle-bar on an ordi-ary machine. Now let him try to use his legs and ighs—as a natural spring, and he will find that to aise his body from the seat he will require to use the ıuscles of his arms and back, and that considerable ffort will be required to lift the weight of his body. till holding the chair back, let him assume a partially rect posture, knees just bent and feet below the ody. This is the position occupied in free-wheeling n a pedal bicycle, except that one foot and crank re in advance of the other. Thus the rider's body s carried on a natural spring formed by his legs, feet, nd thighs with the pivoting point at his knees. That n my opinion is the whole secret of the difference etween a natural seated position on a bicycle and vhat I should call, for want of a better term, a cycle r free-wheeling position. On a cycle one is, so to peak, part and parcel of the machine. If it goes over mound in the road or into a depression, one is made cquainted almost automatically that a shock is oming, and one meets it by the natural spring of the rms and legs.

An Experiment.

Let anyone who rides a pedal or motor bicycle take is machine to the top of a fairly steep hill with a otoriously rough surface. Let him sit in a position, with the legs extended forward and resting on foot-ests, which will bring the feet close to the front mud-guards—that is, with legs at an angle of about 45°; e will find that in this position it is difficult to stand p on the footrests without great assistance from the nuscles of the back and arms. Now in the so-called atural position let him ride down the hill (free-wheeling down without the engine running if he likes), and let his weight rest in the saddle just as though it were on a seat or chair. Let him mentally note the shocks, and return to the top of the hill and ride down again with the legs either on the pedals with cranks fore and aft, or, if there are no pedals, on the customary footrests or anything he can rig up temporarily which will act as a footrest, and allow him to rest his weight partly on the legs or to raise himself from the saddle by merely standing up. Now free-wheel down the hill, and when the machine strikes an obstruction or bumps about let him use the natural flexing action of the legs as a spring, and note the difference in comfort and control of the machine.

If this is carefully carried out I do not think there will be any question whatever in the minds of those who make the experiment as to which is the better seat position for a motor bicycle, one with footrests in front and legs extended, or one with legs more vertical and footrests further back.

Double Footrests.

A good many readers will remember that the Rudge Co. and one or two others fitted double footrests, so that the rider could employ two different riding positions, one with legs and feet extended or with legs nearly vertical. The change of riding position was very beneficial on a long ride. When ambling along quietly on a good surface the extended position was quite comfortable, but immediately speed increased or surface quality decreased most riders of machines fitted with double rests adopted the vertical position, thus bringing their feet back to the rear rests.

Again, examine any good photograph of T.T. riders in motion. One does not see them sitting on a seat with their feet extended in a so-called natural position. The legs are usually nearly vertical, which shows that this is better for controlling a motor bicycle particularly at speed.

I do not, of course, wish to suggest that racing positions should be adopted for touring or ordinary riding purposes, but I think it is incorrect to argue that the seat is superior to the saddle unless it be so made as to give the rider the same leg position as the saddle, when, of course, it cannot be termed a seat.

It must be understood that the opinions expressed above refer to motor bicycles only, single track machines used solo, and not passenger machines, such as sidecars or any form of multi-wheeled vehicle where the machine will remain upright when at rest and does not require to be balanced as well as steered.

Chief of the Penguins.

Miss Violet Douglas-Pennant, sister of Lord Penrhyn, has been appointed commandant of the Women's Royal Air Force.

Petrol after the War.

"Do not be so sure that it will be years before petrol is plentiful when the war is over," said an officer qualified to state such an opinion; "the likelihood is that the shortage of motor cycles will be felt more keenly than the lack of fuel."

Fined for dealing in War Trophies.

Leslie Barrington Taylor, a cadet holding the D.C.M., was fined £5 at Northampton for selling a pair of binoculars and a revolver to Ernest Moss, of Northampton. Moss was fined for making the purchase. Taylor stated that he took the binoculars from a German officer, but had himself purchased the revolver.

A Stolen Motor Bicycle.

In our last issue, under "Current Chat," we published a paragraph mentioning that a twin-cylinder Harley-Davidson motor bicycle had been stolen from outside the Canadian War Records Offices, 15, Tudor Street, London, E.C.4. Fortunately, the machine has now been recovered. It transpires that it is the property of Lord Beaverbrook, Minister of Information, and is used by Capt. J. S Watkins, of the Canadian War Records Office. It was left at the bottom of John Carpenter Street on a recent Saturday afternoon, when there were few people about and the streets were quite deserted. A person wheeled the machine round the corner, and attempted to start it. Now, the Harley-Davidson is fitted with a switch box which controls both the ignition and the lamps, and the switch can only be turned by means of a special key, which he could not find. With the aid of a knife, however, he managed to turn on the electric lights, and after some difficulty succeeded in getting the engine to start, and ran the machine for about twenty miles, when the accumulator ran down. The machine was then taken into a repair shop, and, owing to this fact, it was traced by the police, and eventually restored to its owner.

The Fat Pony Model.

A motor agent of our acquaintance, whose wife wishes to take up solo motor cycling after the war, intends building what he terms a special "fat pony model." The engine will be a single cylinder of about 500 c.c. with a very low compression in order that it will be as docile as the "lady's usual fat pony."

For Promoters of Post-war Competitions.

Plaster of Paris was used to seal the tanks in the economy contest held recently by the Omaha Motor Cycle Club, U.S.A. It is said that this makes an effectual seal, and eliminates any danger of fire, which always is present when sealing-wax is used.

The Institution of Automobile Engineers.

With a view to drawing attention to the advantages which the Institution offers to young men who are being trained for the profession of automobile engineering, a special meeting has been arranged at the works of Messrs. D. Napier and Sons, Acton, for Friday, May 10th, at 6.30 p.m., when a paper will be read by the president, Lt.-Col. R. K. Bagnall-Wild, on "An Examination into the Causes of Failure of Lorry Parts on War Service," followed by one by Mr. G. W. Watson, member of the council, on "Tank Engines." Cards of invitation are obtainable on application to the secretary, 28, Victoria Street, S.W.1.

Belt Drive.

There are still a large number of who prefer the belt drive.

The Motor Cyclist Policeman.

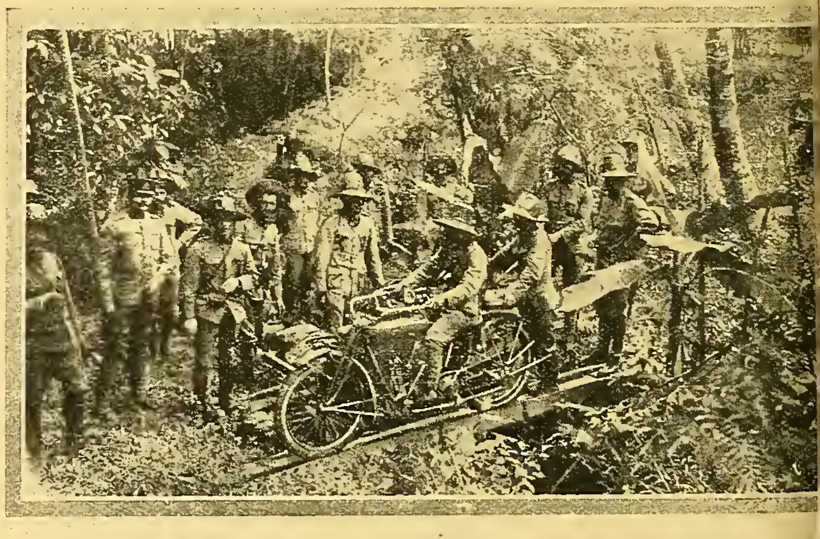
It has been suggested to us that only way to obtain the sympathy of police is to have them mounted on cycles.

Roads Improvement Association.

At the Roads Improvement Associ meeting on Thursday, April 25th, Percy Boulnois, M.Inst.C.E., was ele chairman in place of the late Mr. Ro Todd, and Mr. W. Worby Beaun M.Inst.C.E., M.I.M.E., vice-chairma

A Notable Flight.

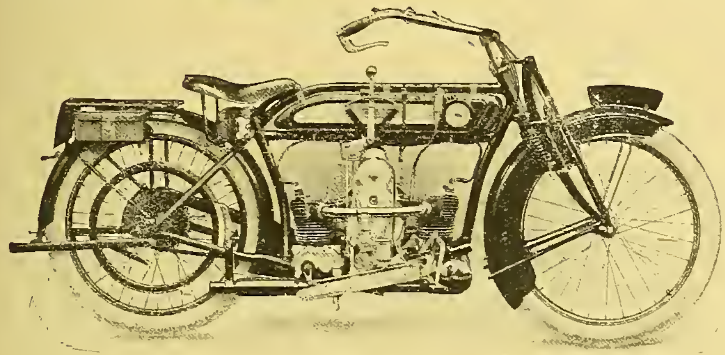
We read that, in a discussion on pluckiest flying feat on record in R.F.C. mess in France, the place honour was given to Blériot's memor flight from Calais to Dover in J 1909. The machine had never previo been in the air long enough to cross Channel, and it was uncertain whe it could maintain sufficient height alight on the cliffs.



During recent Java army manœuvres Indian motor cycles were used by despatch riders. The photograph shows some of the difficulties encountered whilst passing through the tropical jungle.

Humber

The whole of our present output is reserved for the Governments of the Allies, but may we put your name on our Waiting List?



3½ H P. TWIN HUMBER.

"We have just taken down one of your motor cycles," writes an agent in Port Elizabeth, "after doing 9,000 miles, and, except for a slight deposit of carbon, she was in prefect condition, and none of her bearings need attention. The tyres also have never been replaced, and are good for a few more thousand miles. We are circulating this against the American machines, which shake loose after 2,000 or 3,000 miles, and whose tyres rarely do more than 1,500 miles on our roads."

orts to Australia.

ccording to official figures, the following were the imports of motor cycles and s into the Commonwealth of Australia the year 1917 :

United Kingdom ...	£27,818
Belgium	110
Germany	32
U.S. America	132,248
Total	£160,208
Duty collected	£48,526

Death of M. Taride.

To those who have toured in France the name of Taride is indeed a familiar one. The Taride maps and road books are the best known in that country. The maps are excellent, being clear and accurate, while the road books give plenty of information in a most lucid manner.

This Month's Moon Chart.

We are in receipt of an excellent moon chart for the month of May got out by Mr. A. H. Midgley, of Messrs. C. A. Vandervell and Co., Ltd., Warple Way, Acton Vale, W. Since our last reference to this it has been considerably improved. The phases of the moon are more clearly indicated, and a broad white line running down the centre of the card indicates midnight. A study of this chart is of value at the present time.

Induction Pipe Design.

In the article in this issue on the question of the design of induction pipes, it is mentioned that the Henderson motor cycle is fitted with induction and exhaust manifolds cast in one. In America, induction pipes made on this principle are also obtainable ready for fitting to one's own car. It would appear that some such arrangement will be necessary for the English motor cyclist after the war.

The Modern Broncho.

Our U.S. contemporary, *Motor Cycle and Bicycle Illustrated*, publishes a photograph of a Western motor cyclist "who finds sport in roping calves." We agree with our American friends when they say: "Our idea of fun runs in other directions from chasing a fool calf around a ten-acre lot, driving a motor cycle with one hand and swinging a lariat in t'other. But even so, chasing him isn't in it for a minute, as far as excitement is concerned, as when the fool calf is roped. Then things begin to happen in large quantities, specially if the calf manages to get the rope all messed up in wheels and things, as he usually does."

The Single-geared Machine.

One sees very few single-geared machines in use at the present time, which rather shows that for utilitarian purposes, even as solo machines, some form of change speed is necessary.

A Gallon of Petrol or Five 2 lb. Loaves of Bread.

In every munition factory a Government poster reminds petrol users that the carriage of a gallon of petrol across the Atlantic involves space equivalent to that occupied by material for five 2 lb. loaves of bread.

Soulless Mechanism.

A petrolless motor cyclist in discussing lawn mowers and other garden and household machinery, described it as soulless mechanism, and cast longing glances towards his "bloodless" motor cycle in the shed.

Hoods and Screens on Single Trackers.

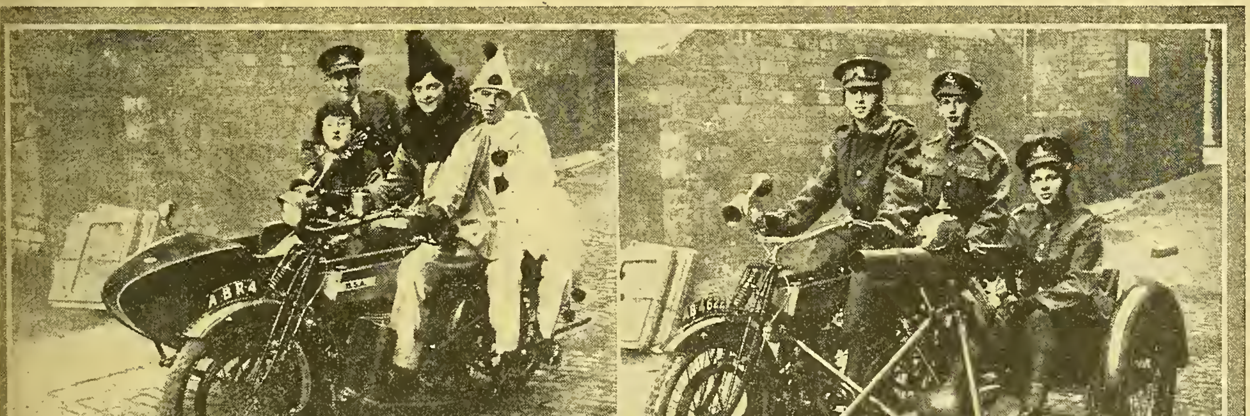
A Henderson enthusiast in America has built a canopy embodying an adjustable windscreen for his motor cycle. This cover protects the driver and his pillion passenger from rain and sun. We are not told whether side curtains are fitted for the worst weather!

Standardisation of Engine Valves.

At a recent meeting of the Society of Motor Manufacturers and Traders the question arose regarding the standardisation of valves for motor cycle, light car, and car engines. The matter was directed to be placed on the agenda, and members interested are asked to communicate with the secretary

Kingston Again!

The Kingston justices have fined a motorist 20s. under the Motor Spirit Restriction Order for use of motor spirit for taking out wounded soldiers. The defendant held a permit for the purpose, but it related to another vehicle. The Mayor said that he could not understand, if it was for the officer's health, why one vehicle should not be as good as another.

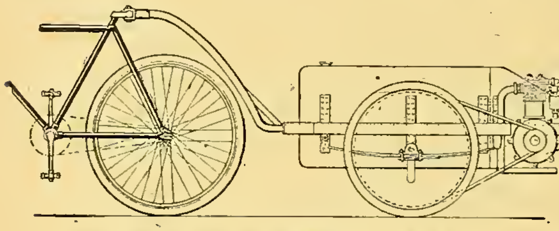


A B.S.A. sidecar and a machine gun outfit which took part in a recent Tank procession. The drivers in both photographs are lady employées of the B.S.A. Company.

A MOTOR-PROPELLED TRAILER.

A Modern Invention more Amusing than Useful.

AMERICA is not the only home of queer ideas in motor mechanics. The Continent of Europe has produced enough "contraptions" to justify at least a share of any claim. Usually, however, it is found that Europe's contributions to the world of "freaks" are old ones, and excusable because they appeared when autocars and cycles were young.



A queer patented idea for propelling a pedal cycle by means of a motor trailer.

The subject of the accompanying illustration is a recent patent of two French engineers, and, in the words of the specification, "the invention has for its object a self-propelled vehicle forming a detachable carrier capable of being fitted to the rear of a bicycle or cycle of any kind."

As will be seen from the drawing, the vehicle comprises a sprung chassis carried on two wheels, one wheel being driven by an air-cooled engine, apparently of about 3½ h.p.

We are informed that all the controls (ignition, decompressor, and braking are mentioned) are arranged conveniently for the hand of the driver, who "sits on the machine in the ordinary manner."

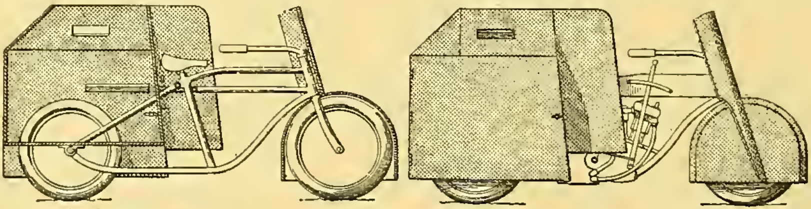
It will occur to most readers, no doubt, that, to be efficient, a change-speed gear and a clutch would be essential, and that the cost of such an outfit would be little, if any, less than that of a sidecar combination. Under these circumstances it would appear that a vehicle of this description does not justify the expenditure incurred in patenting the invention, if such it can be called.

AN ARMOURED TRICYCLE.

An American "Invention" resulting from War Fever.

WHEN the war was a novelty in 1914 and the early part of 1915 many pseudo-inventors in this country attempted to adapt the motor cycle for special purposes of warfare. An "armoured" sidecar was one of these: but as it afterwards transpired that the army grey paint covered three-ply wooden panels instead of armour steel, one could excuse the builders on the score of their publicity providing astuteness. The same excuse does not serve with the subject of the accompanying illustration: in this case we have a serious attempt to design an armoured motor cycle, for which the inventor—Mr. F. M. Goddard, of Brooklyn—has secured a patent. According to the specification, the armour consists of a steel plate protection about the vulnerable parts of the motor cycle, and a steel cab for the driver. There are portholes for rifle fire, and an enclosed steel box over the rear wheels which is intended to accommodate two passengers.

If the drawing gives any true indication of the thickness of the armour plate, we think the inventor would have difficulty in finding a motor cycle engine sufficiently large to propel the weight. In the vernacular of the land of its birth, the patent offices over there must think "it is a shame to take the money." We publish the drawings for the entertainment of those many readers of *The Motor Cycle* who know what real war means, and how useless such a contraption would be.



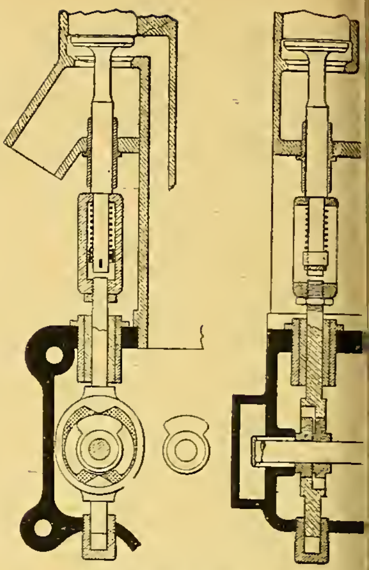
A freakish design for an armoured motor cycle that was recently patented in America.

POSITIVE VALVE OPERATION.

An Experiment of a Much Discussed Topic.

WE illustrate on this page a positive cam mechanism invented by Mr. Leonard Hinks, and capable of being applied to any four-stroke motor cycle engine. The engine of ordinary design has to open its valves against a considerable spring pressure, as well as against the pressure of gas in the cylinder (in the case of the exhaust valve). This consumes an appreciable amount of power. For example, suppose a single-cylinder motor cycle engine to be running at 2,000 r.p.m., each of its two valves opens 1,000 times per minute a distance of about ¼in. against a spring pressure of approximately 30 lb. The h.p. required for spring compression alone is $\frac{500 \times 30}{12 \times 33{,}000} = \frac{1}{26}$ h.p. roughly. Moreover, the spring pressure is the source of wear on the cam wheels, rockers, and tappet, etc.

The spring in the Hinks valve comes into action only at the moment of closing, and its objects are to ensure the absolute closing of the valves and to prevent bouncing or chatter on the seats. The barrel enclosing the valve stem is open



Sectional drawing of the Hinks positive valve mechanism.

on either side to enable the spring tc
placed in position. It will be seen
one cam wheel opens the valve
another closes it. The lift as show
somewhat abrupt, a desirable point
regards speed, but liable to cause nc
and some modification may be fo
desirable. The valve is to be te
shortly on a B.S.A. engine. There shc
be no stretched valve stems with va
operated on this principle, nor should
springs need renewal.

To Overcome the Difficulties Imposed by the Paper Shorta

THE MOTOR CYCLE AVIATION SECTION

The enormous importance of the Air Service needs no emphasis: it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouraging of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

When?

Ionths ago a new House Magazine of
Royal Air Force was promised, and
cash prize was offered for the best
ggested title. Is the delay due to the
ficulty in determining the winner?

◆

V.C. Airmen.

The King has been pleased to award
Victoria Cross to Lt. Alan Jerrard,
A.F., and Sec.-Lt. Alan Arnett
Leod, R.A.F., for services displaying
standing bravery.

◆

lowances for R.A.F. Uniform.

Officers of the Royal Air Force are to
vide themselves with one suit of the
v uniform without delay. To assist
cers in obtaining uniform of the
tern approved for the Royal Air
rce, a grant of £10 is to be made from
blic funds to officers who have already
eived a khaki allowance, and £30 to
val officers if they hold field rank; and
5 to naval officers up to the rank of
ptain in the R.A.F.

◆

An Extraordinary Feat.

Some of the most plucky, not to say
ir-raising, feats are done in air far
noved from the fighting areas. On one
casion at an aerodrome in England a
in-engined pusher machine was being
sted, and it was taken into the air with
e fore and aft trim so bad that the pilot
und it impossible to come down to earth
ain without risking an almost certain
ash. To put matters right a mechanic
o occupied the rear seat got out on to
e fuselage and crawled along it between
e two screws, which can only have
ssed him by a few inches. He then
mbed over the pilot and got into the
nt seat, the alteration in weight dis-
sition being such that the machine was
t to earth safely. On more than one occasion observers at the Front have enabled aeroplanes to get down safely, when part of the wings had been shot away, by getting right out on the opposite plane and so "trimming the ship." And this in a relative wind of anything up to 100 m.p.h. Compared to this sort of work, squirrels on top branches and chamois on the brinks of precipices have cushy jobs indeed.

◆

AIRMEN MOTOR CYCLISTS

The Rev. R. M. Bankes-Jones, curate of Sunningdale, Berks, was, prior to the war, an enthusiastic motor cyclist, and a frequent contributor of touring articles to *The Motor Cycle.* His series of articles dealing with tours in "Lorna Doone Country" will doubtless be remembered by many of our readers. Having spent some time at the Front as an Army Chaplain, he became possessed of a desire to join a combatant unit, and accordingly relinquished his chaplaincy so that he might train as an R.F.C. pilot, and in his activities we wish him the best of luck.

Sec.-Lt. (the Rev.) R. M. Bankes-Jones.

A Royal Souvenir.

From a Surrey aero engine works that he visited recently the King took away a cylinder from a damaged engine as a souvenir.

◆

"Spars."

In the light of the various resignations among leading officials of the R.A.F., "Spars" would seem to be a suitable title for the new House Magazine of the third arm of the Service.

◆

The "Brass Hats."

The Strand almost glitters these days with "brass hats"—now worn by R.A.F. officers of field rank. Lieutenant-Commanders of the R.N.V.R. have been given the rank of major, which accounts for so many gold leaves.

◆

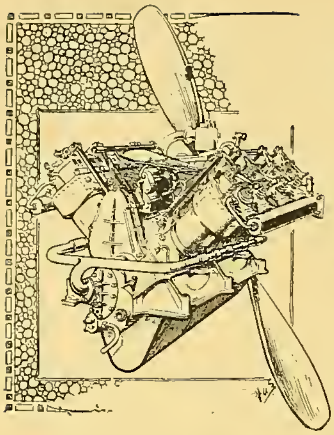
Director General Wanted.

The Aircraft Production Department is now located at its new home in Kingsway. At the moment of writing the department is without a Director General in consequence of Sir William Weir's appointment as Secretary of State to the Royal Air Force.

◆

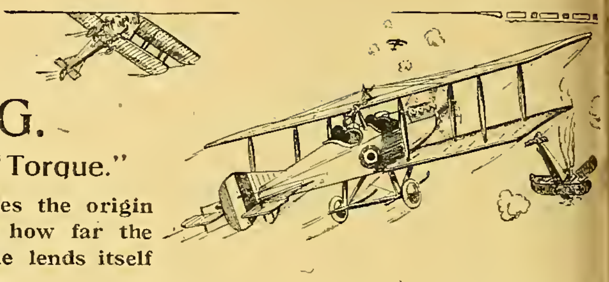
Dodging Howitzer Shells.

Several people have expressed a wonder that with the air over the lines constantly full of flying howitzer shells, aeroplanes do not occasionally run into them. They do; and it speaks volumes for British aeroplane construction that in several cases the unfortunate occupants of an aeroplane which has stopped a shell have been able to get home and tell the tale. Not very long ago a reconnaissance machine was landed at its aerodrome with two of its four fuselage booms knocked out by a direct hit from a big howitzer shell, which killed the observer and left but little of his cockpit intact.



STUNT FLYING.

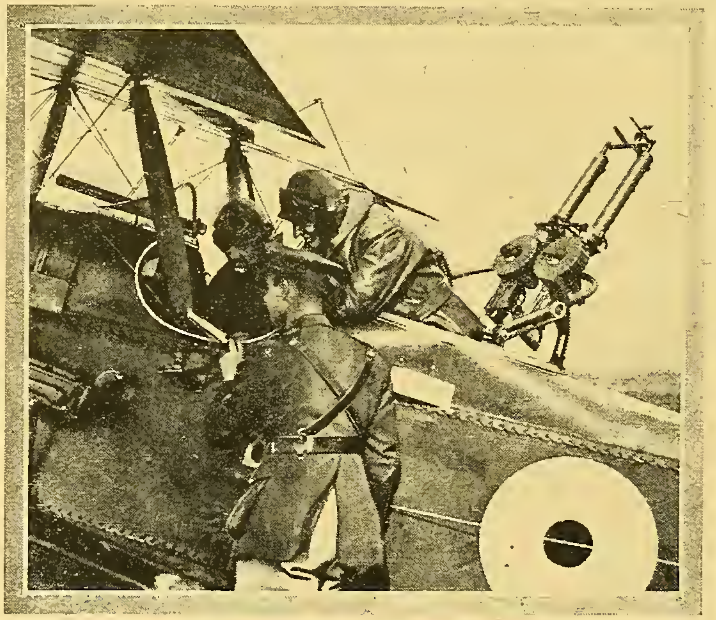
Part II. By "Torque."



Our contributor examines the origin of "stunts," and shows how far the structure of the aeroplane lends itself to trick flying.

At least two of the commonest tricks employed by fighting pilots were never invented at all. Just as Fritz cannot help being the unspeakable Boche, so no aeroplane is proof against slides and spins when due occasion arises. If a 'bus is overbanked in turning, it may or must develop a wing slide, varying in intensity according to the speed, angle, etc. If a machine is made to climb at too steep an angle, it will "konk" out as a baby two-stroke would if driven at Tornapress: only in this case the failure takes the form of a tail slide. Similarly, if an aeroplane is put into a very sharp descending turn, that turn will develop into a corkscrew or spin, unless the controls are operated; and, for reasons to be explained in another article, the primitive aeroplane usually kept on spinning when it once started. Indeed, a book published since this war broke out announced that no pilot had ever got into a spinning nose dive and lived to say what it felt like. Some of the simpler "stunts" were originally not so much invented as experienced: and the pioneers in these particular lines usually had no chance to discuss their sensations with anybody but the angels.

As time went on, an odd pilot or two managed to wrench his machine out of an involuntary stunt. When he came down, and got his breath back, and his pulse slowed down, he reasoned the matter out. A very daring man would go up again, provoke a repetition of the stunt, and test his theory as to the proper remedy. If he was right he had added a fresh trick to his *repertoire;* if he was wrong, he donned a pair of wings which are less coveted by most people than the blue and white chest mark of the R.A.F. pilot. Meantime, designers were doing their bit. In the course of time a situation which had once mea sudden death deteriorated into pure "swank," a when war broke out became embedded in our stere typed fighting tactics.



THE GERMAN OFFENSIVE ON THE WESTERN FRONT.

Pilots bring in their reports as to the position of the enemy. Note the machine guns fixed at the rear of the pilot's seat.

How the Loop Stunt was Invented.

Other stunts were the invention of genius, notab the loop. Pégoud, the renowned French crack, co ceived the idea of looping long before he had a chan to make experiments. When a machine is the rig way up the principal load comes on the "flying wires, which are very strong and run in duplicat Luckily Pégoud knew too much to try a loop tl instant the notion came to him, for when a machine upside down the principal load comes on the "lan ing" wires, which were designed in those days to c little more than carry the weight of the planes whi the machine squats st tionary on the aer drome. So Pégou asked Blériot to buil a special 'bus, stiffene to fly belly upwards Blériot refused wit oaths, so to speak finally he complied, an Pégoud looped hun dreds of loops. Th value of his stunt wa not recognised at th time. He was re garded as a cross be tween an advertisin agent and a music hal mountebank, plus the slight added glamou due to the enormous risks he appeared to be running. Now we can honour Pégoud at his true worth. He takes his stand with the man who invented creeping barages, or the testudo of the Roman legionaries, or the Macedonian phalanx, or any other special tactic which has revolutionised warfare for a space.

Nowadays, the catalogue of major stunts is probably full. It does not seem likely that any fresh manœuvres as distinctive as the loop remain to be invented. This is a daring statement, but the fact that many thousands of scatter-brained young dare-

tunt Flying.

devils are sighing in vain for new tricks to conquer, makes it doubtful whether many wholly novel dodges can be unearthed, or deskied, or whatever the appropriate term is. Minor stunts keep occurring to somebody, such as the Immelmann turn, which is simply a combination between a half-loop and a vertical bank.

The Question of Stability.

This rapid exhaustion of the list of conceivable stunts was inevitable as soon as a pilot could try a new stunt without paying the penalty with his life: and it is a remarkable fact that stunts are possible because a modern aeroplane possesses enormous automatic stability, which stability can be converted into hopeless instability by a slight movement of the hand and as rapidly restored. This is not the place to insert an essay on stability: but, briefly, the early Wright biplane was being corrected by the pilot for balance in one direction or another during almost every second that it flew. It was practically devoid of any natural or automatic stability whatsoever. As a mule is perpetually seeking a chance to kick its driver's brains out, so was the Wright aeroplane eternally seeking how it might destroy its pilot. By contrast such a machine as the BE2C can almost be flown by a sack of potatoes. In nice weather one might put a Teddy Bear in its cockpit, open the throttle, remove the chocks, and lo! the BE2C would rise aloft, fly till its petrol tank was empty, and then glide safely to earth, supposing it had the luck to alight on a nice piece of turf, and not in a graveyard among the tombstones. In other words, a stable modern aeroplane cannot give a lurch in one direction without bringing into action some surface which automatically tilts it back on to its correct path. Consequently the pilot who wishes to stunt needs but three things, viz.:

(1.) A cool head.
(2.) Sufficient altitude.
(3.) A tolerably stable machine.

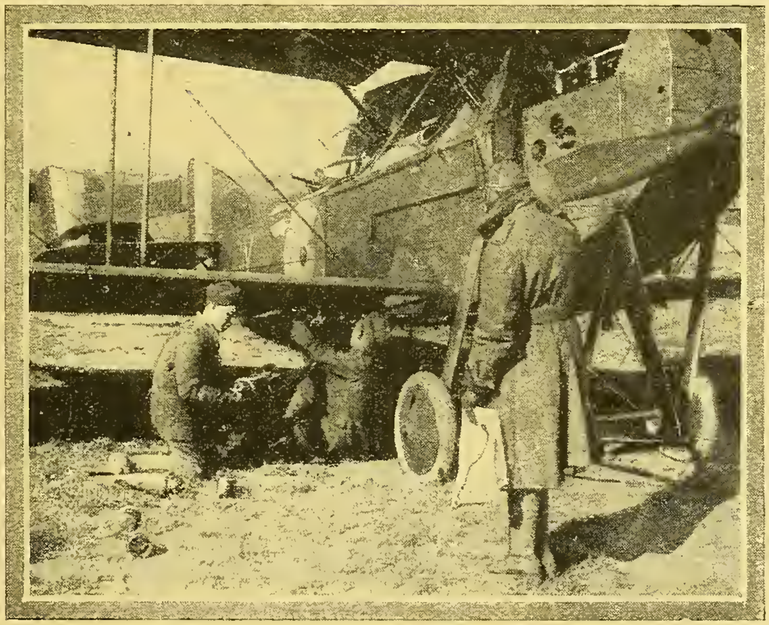
Let the Plane Right Itself.

The proof of this assertion is that many living pilots have actually looped the loop during their first solo flight! Let me explain. The cool head is necessary, because the unskilful pilot must not try to right a stunting aeroplane—he must let it right itself. If he throttles down his engine, so that its thrust becomes negligible; if he puts all his controls in neutral, leaving the automatic stability to right the aeroplane, while he sits idle and tries not to get the wind up, the machine will sooner or later put itself into a natural angle glide. He can then flatten out into horizontal flight, or land, as the mood takes him. The lateral stability factors will ultimately bring the machine on to a level keel: and the fact that it is nose-heavy when the engine is not thrusting will ensure the glide.

Since these processes take time, a certain amount of altitude is essential. Any good modern aeroplane will automatically get itself out of a side-slip, or a tail-slide, or any other frightful-looking situation, if there is sufficient room beneath it: but the job may involve a drop of 1,000 feet or more. Consequently stunting at altitudes is always safe: stunting near ground level is always dangerous, though crack pilots can do it and live.

A Cross between a Bath-chair and a T.T. Racer.

To conclude, we must explain one apparent paradox of which these notes will be accused. The natural stability of modern aeroplanes has been justly emphasised: and yet this alleged stable machine can make its wing-tips chase each other so fast that the machine almost looks like a blur against the sky. How can this weird "manœuvrability" be termed "stability"? The answer is simple. The stability is there, right enough, as long as the control surfaces are left in "neutral"—*i.e.*, ailerons lying out as continuations of the wings, rudder central, and elevators in line with the camber of the tailplane—the machine is tremendously stable. When the pilot has traced out a path which, if charted, would resemble an eel having an epileptic fit in three pounds of Berlin wool, he just centralises his controls, and the machine rights itself infallibly after quite a short drop. The instability is also there. The controls of a scout machine, designed for crazy manœuvre, are of enormous area compared to the total lifting surface. It is like a racing car equipped with the steering lock of a taxicab. The instant the giant controls are operated the stability is wiped out by their leverage: the instant they are neutralised the natural stability is restored. The fighting scout is a hybrid between a bath-chair and a T.T. racer.

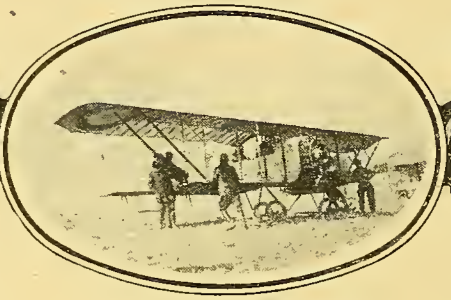


ON THE WESTERN FRONT.

Fixing bombs to drop on massed German troops. (*Official.*)

THE FUTURE AND COMMERCIAL AIRCRAFT.

The Possibilities of employing Aircraft for Regular Passenger Service.



BY A R.A.F. OFFICER.

EVERY now and then we are regaled in the daily press with more or less imaginative descriptions of flying when peace reigns once more. Delicious vistas of breakfast in London, lunch in Paris, and dinner on the Riviera unroll before us. No longer are squeamish stomachs to recoil at Channel crossings—no longer the struggle and confusion at the railway stations—nothing but the limitless air to surround one. A glorious vision, but how many of us will ever see it happening or still more ever experience the like?

If peace reigned now it would be possible for anyone who cared to pay the bill to do the trip thus defined in one of the present day war planes. It is not the possibility that is in doubt, but the question whether anyone wants to carry out such excursions. When one reads of daily journeys by air being established after the war between London and Paris, one is apt to forget that a pretty regular service of planes is now, and has been for a long time, running between the two capitals. But, as things are, the journey is very uncomfortable—tiring for the pilot and cold and cramping for the passengers.

Thus, in order to decide how aviation may be commercialised after the war, it is necessary to consider what manner of machine may be likely to be used most extensively. At present it is often said that aircraft have been perfected by the war. Rather may it be said that the war has been perfected by aircraft The present-day machine is built purely from a military standpoint, and, broadly speaking, embodies as much engine and as little aeroplane as may usefully be employed. All this must be changed when peace comes. The situation is analogous with the early history of motor car touring. Huge engines and little cramped bodies rapidly gave way to small engines and commodious accommodation. So must it be with aircraft. The first necessity of any peace-time development is to make that development pay, and there can be no doubt that all aircraft as we now know it—even of the Zeppelin type—must be vastly modified before aviation can possibly become a commercial proposition. Probably some wild-cat enterprises will be rushed on a credulous public directly hostilities cease, but few of these are likely to bear the light of skilled criticism.

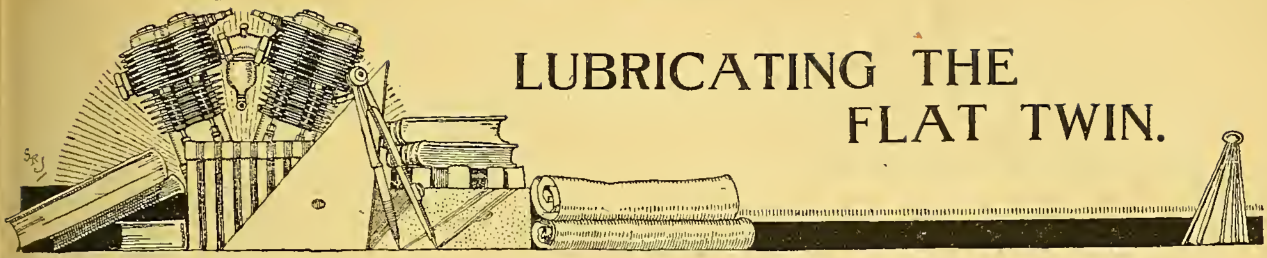
Safety of Primary Importance.

In the opinion of the writer, who has had some considerable opportunities for close observation of several types ot war planes, the peace-time passenger - carrying plane will be very much removed from the present conception of most aeroplanes. The primary importance of safety must be studied if flying is to be accepted by the many-headed. At present safety is dependent on two main factors—reliability of the engine and skill of the pilot. Engines must be improved and duplicated, and probably some means of direct lift will have to be embodied as a means towards greater safety, and also as a means of improving the gliding angle and rising angle. This will be necessary in order to reduce the size of the aerodromes. To ensure quick transit from the public service dromes to the adjoining cities the landing places must be close to the centres of the cities, with the inevitable result that the land will be dear and economy in space imperative. For it must be remembered that reasonable cost is essential if aerial travel is to be common, otherwise the railways and motor omnibuses will continue their monopolies of passenger carrying unchallenged. For the only *real* advantage of aerial travel will be speed. It is difficult to see any very immediate future for aerial traffic in goods, and thus that high revenue now enjoyed by the railways is unlikely to be challenged seriously by aerial cars.

Goods Traffic.

It is the goods traffic revenue that permits a penny a mile fare for passengers on railways, and thus it will be seen at once that, in order to stand a reasonable chance of success with nothing but passengers and perhaps very light goods as customers, it will be necessary for any aerial navigation company to study every penny of expenditure. Probably the greatest saving to be effected will be in reduction of land charges, and this leads the writer to believe that direct lift—one of the greatest revolutions ever likely to be effected in aircraft, for it means the possibility of hovering stationary—will be brought about through financial considerations: a factor which generally acts with greater force than any other agency in the realms of invention.

As regards the type of aerofoil likely to survive, in all probability the flying boat type has an enormous field for development before it. Prophecy is notoriously rash, but, all things considered, the writer suggests the flying boat, equipped with a combination land and water carriage, as the type along which commercial aerial navigating craft is likely to be developed.



LUBRICATING THE FLAT TWIN.

Some Suggestions for Overcoming a Common Weakness.

THERE is one almost inherent drawback in horizontally-opposed twin motor cycles which undoubtedly stands in the way of their universal popularity. The man who is accustomed to the breed and knows their little ways is not much concerned by this fault, but ask the rider with but a smattering of experience—ask the man who knows them only by hearsay—and the invariable opinion is, "The oiling is such a beastly nuisance."

It must be admitted that one well-known make is fairly good in this respect, but with the majority of flat twins the lubrication is too ticklish for the ordinary amateur who employs hit or miss principles. The least indiscretion at once leads to a smoky exhaust and plug troubles, and the majority of flat twins being high-revving engines, the novice seeks safety in erring in the direction of liberality. As a matter of fact, if the engine has big-end roller bearings, the oil supply can safely be cut down to a very small allowance without risk, but the art of handling an imperfect system of lubrication to a nicety is an art in itself, which can only be acquired by troublesome experience.

Plugs and Lubrication.

I am convinced that there are scores of riders who eschew flat twins simply because they are afraid of the oiling. Unless one runs the engine rather on the dry side, one can count on having to fit at least one new plug per month. The plug is apparently perfect in every way, yet nothing will induce it to behave in a decent manner. Probably it has been carefully cleaned at the roadside on several occasions, but the constant saturations of oil appear, in some way, to destroy the properties of the insulating material, so that the spark is intermittently weak and strong, or probably disappears entirely at irregular intervals. No doubt the users of petrol two-strokes have experienced similar troubles.

Given a perfect lubrication system, plug troubles will no longer be so intimately associated with the flat twin engine. Practically all plug troubles have lubrication at their root, and the common defect in flat twin engines is that the faintest overdose at once flies to the head of the rear cylinder, and staggering, etc., begins.

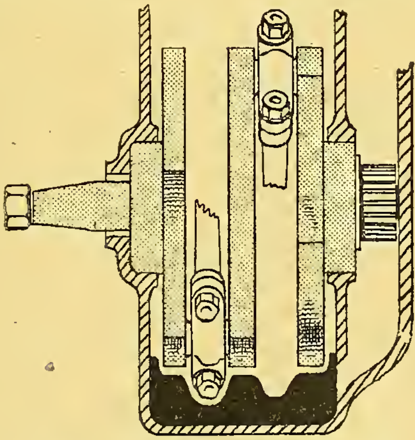


Fig. 1.—There is a theory that at high speeds the oil tends to retain the contours formed by the passage of the crank and connecting rod ends through its surface. The higher the speed the less oil thrown up.

The cause of this state of affairs is pretty obvious—splash feed. If we are to equalise the lubrication of both cylinders then the cranks must not dip at all. Obviously, if they do, the bulk of the oil is flung into the back cylinder, and by the time the front cylinder crank is at the top it is pretty well dry, so that the front cylinder receives not one-tenth of the supply received by the back. It is doubtful, indeed, whether it receives any at all by means of splash, but rather it is fed on oil vapour.

The Question of Oil Level.

Splash feed, therefore, may be all right for vertical singles, but even when the cylinders are set at 45° its inequality of distribution begins to show. Thereafter, the wider the angle of the cylinders, the more uneven the distribution. With a 90° twin the limitation of the splash system is more than reached, and with an opposed twin it may be described as a hopeless proposition. One can fit baffles or do what one chooses to prevent the excess reaching the rear cylinder, but without effect. Immediately the cranks begin to dip a veritable deluge is cast directly into the rear, whereas the front remains practically as usual. Obviously, baffles are of little use under such conditions.

It is assumed, of course, that the oil in the crank case retains something in the way of a level. I have many times heard practical riders and manufacturers say that the oil level theory is merely a myth—that when the engine is running the oil in the crank case is simply a churned up fog, and that there is no level.

This is probably an entirely incorrect idea. The very fact that in a twin-cylinder engine more oil is thrown into one cylinder than the other surely proves conclusively that there must be something in the way of a level. That the crank case is filled with a heavy oil fog cannot be doubted, but this does not exclude the level idea. What probably—one might almost say obviously—happens is that the surface of the oil forms itself into an exact contour of the disturbed area, as shown in the accompanying sketch, which is a section through the crank case parallel to the main shaft. The higher the speed the more perfectly is this contour retained, and therefore the less the oil flicked into the cylinder at each revolution. As the speed falls, the oil has longer between each assault

Lubricating the Flat Twin.—

of the crank to assume its natural evenness of surface, and therefore more oil has to be displaced when the big end and crank descend and strike it.

The greater the mass of oil in the crank case the more forcibly it strives to retain a level surface, and of course the thinner the oil is the better it succeeds in doing so. This is why an oil which is stiff by nature, or stiff because the engine is not yet properly warmed, is less likely to cause trouble than a thin oil. It assumes its contour and sticks there, the cranks displacing very little at each throw.

It may be taken that the small amount of air imprisoned in the crank case is capable of consuming only a given quantity of oil fog or vapour. When the point of saturation is reached the surplus oil is flung about in solid chunks, and it is these solid chunks that cause the trouble.

Big End Bearings.

One word now concerning big end bearings. It will be seen from the foregoing that the higher the engine speed the smaller is the amount of oil that actually comes in contact with the big ends. Similarly, the higher the speed the greater the centrifugal force tending to throw off what little oil is really successful in reaching them, and this is why so much trouble is experienced with big end bearings in racing engines. The crank case can be kept so full of oil that the cylinders are flooded, yet owing to the conditions described the big ends contrive to run dry. This, then, goes to prove that splash feed is further a defective system so far as big end bearings are concerned, and these bearings, to be properly supplied, must be fed through the hollow crank, in which case centrifugal force assists the oil to reach them in a constant flow, rather than hinders it from doing so.

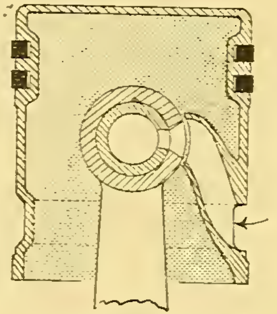

Fig. 2.—This piston has a circumferential oil groove which comes opposite the oil feed pipe at the bottom of each stroke: a lead is taken inside to the gudgeon pin.

The above, however, refers only to plain bearing big ends. If rollers are used, it is entirely unnecessary to make any provision whatever for oiling them. Roller bearings require so little oil that the oil fog alone fully satisfies their needs, and if the pistons and cylinders would stand it, a roller bearing engine might safely be run on one charge per 1,000 miles. My idea is to employ the same principle, as in the A.B.C., with regard to threading on the roller big ends.

Hot Oil.

The foregoing, then, has as its purpose the proof that the very necessary step for the improvement in flat twins is in the oil system, and in order to improve this manufacturers must get clean away from their old friend splash feed. It has served well with the single, and fairly well with the 60° twin, but the latter marks its limit as a successful system. We must do away with the oil sump entirely, and, rather than depend upon splash, we must attempt to eliminate it—that is, the cranks and big ends must not dip. The oil must be conveyed to the desired spots at the desired rate, there do its work, and drain quietly away—possibly to be recirculated. This system of distributing oil is, of course, adopted with entire success on rotary and many other complicated engines, and there is no reason why it should not prove more successful in the case of the comparatively simple motor cycle engine.

Obviously a circulating pump is necessary, and it need hardly be pointed out that the principle of keeping a large quantity of cold oil freely circulating is infinitely superior to that of leaving the engine to depend upon a little imprisoned oil. In the latter system, in general use to-day, the small amount of imprisoned oil becomes so hot that its lubricating qualities are seriously interfered with, and it is little better than so much paraffin; then, when a fresh charge is fed, its beneficial effect is but momentary, for in two minutes it is diluted with the rest, and the state of affairs gradually gets worse as time proceeds. Thus for ninety-nine per cent. of the time the engine is dependent on hot, thin oil, lacking substance and retaining heat instead of absorbing it; obviously a system feeding a cool, fresh flow all the time would be much preferable.

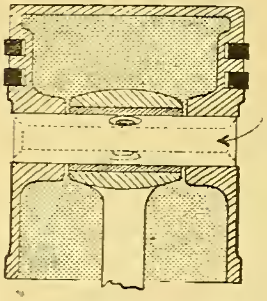

Fig. 3.—A hollow gudgeon pin having countersunk ends and drilled for lubrication of the little end.

Feeding the Small End.

The separate oil tank, occupying part of the space that might profitably be occupied by petrol, will soon become extinct—"and a good job too," as George Robey says. We do not want oil taps and oil pipes and oil pumps distributed here and there, collecting dust, liable to injury, and adding to the general ugliness of things. Permit us to keep our tanks as dry and clean as possible, and let us have no more pipes and taps than are absolutely necessary. There is a proper place to carry the oil and only one proper place—inside the aluminium casting of the crank case—Douglas and Velocette practice. The excellence of this idea is too obvious to need enlarging upon. It is clean, simple, and as things should be, and once having poured a quart into the crank case, we shall be all the happier if we are at liberty to forget all about it for a few hundred miles, as one is at liberty to do with the 3 h.p. Enfield and the Velocette—it being taken, of course, that we have a finely threaded adjustment screw to allow for variations in temperature.

Assuming that we have roller big ends and crank case bearings, the only points to which oil need be led are the pistons and the gudgeon pins, the latter presenting the greater difficulty. A simple method would be to force oil to the piston, and thence convey it by means of a lead to the gudgeon pin bearing (fig. 2). Another way would be to use a piston shaped as shown in fig. 3, having a wide oil-retaining groove, through which the gudgeon pin passed. A hollow gudgeon pin, drilled to lubricate the small end, could then be employed. Yet another way, and perhaps the simplest bricating the Flat Twin.—

f all, would be to have the gudgeon pin a driving t into the connecting rod with bushes in the piston self, and lubricated directly from the piston walls.

All these systems would convey plenty of oil to he little end on account of the fact that on one side here would be what pressure was created by any light escape past the rings, while on the other side ould be crank case suction.

Oiling the Piston.

Any gas that gets past the two top rings may be ritten off as a dead loss, and therefore having made his provision, we are at liberty to design the remainder f the piston in accordance with our oiling system. We are aiming now at a system which feeds a goodly supply to the piston—a constant flow of fresh oil which will not only lubricate but also cool. This given, it will be sufficient for all speeds and all conditions—practically eliminating the necessity for adjustment—so long as we make provision not only for getting the oil there but also for getting it away. We must, therefore, allow it to escape freely, and the obvious course is to use a slightly waisted piston drilled round its skirt. It should not be too freely drilled, however, for whereas in ordinary practice one object of drilling a piston is to enable the oil to reach the cylinder walls from the inside of the crank case, in this case the object is to enable the oil to reach the inside of the crank case from the cylinder walls. Having a drilled piston the small end would probably receive a copious supply, even though no other provision were made for oiling it.

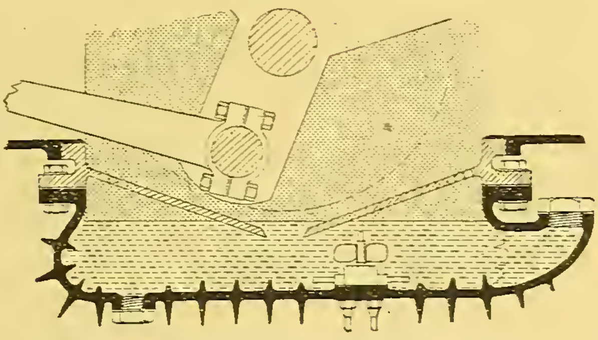

Fig. 4.—Suggested design of crank case with false floor and oil sump below containing a pump immersed in the oil. The whole sump can be detached with the pump *in situ*. The pump is equipped with a small fan or propeller to keep the oil moving.

The reader may ask, "What happens if the pump strikes work?" What happens if the pump of a rotary strikes work a few miles behind the Hun lines? There is no earthly reason why the pump should strike work, or at any rate present-day pumps do not do it. In over 10,000 miles with mechanical pumps, some of them of the experimental variety, I have known them to do all sorts of whimsical things, but never to strike work.

I think that if provision were made to allow the oil to escape freely from the piston, it would not reach the combustion head in excessive quantities, provided, of course, that the cylinders and pistons retain their rotundity, and if they do not, trouble will ensue with any variety of oiling. With splash lubrication, oil is likely to get past the rings because the deluge of oil flung up against the inside of the piston is so terrific, when an overdose is admitted, that it exceeds all comparison with the most excessive supply that would be fed to the cylinder walls.

A Suggested System.

The general idea roughly planned out in diagrammatic form is fairly obvious without description. The oil sump is situated beneath the crank case, which forms, as it were, a false floor, more or less conical in shape, and having a single drawhole at its bottom extremity. This position would detract somewhat from the crank case clearance, but since it may be taken that the bottom of the flywheel will still be the lowest point of the engine this does not matter much. The sump is provided with cooling fins to keep the oil at a low temperature, and it contains, below the oil level, a worm-driven pump for feeding the supply to the respective cylinders, thus eliminating the use of outside fittings, which accumulate dirt and are susceptible to damage. The supply to each cylinder would be adjustable, and the sump can be detached bodily, with the pump *in situ* and readily accessible.

The Sump.

The drive to the pump would not extend, of course, outside the crank case, and the oil from each of the cylinders would drain immediately back into the sump when it had done its work. It would be impossible for oil to drain into the cylinders with the engine standing, and therefore no tap of any kind would be required.

In this we have a positive system, which may be taken as preferable to one depending upon that uncertain quantity, crank case suction.

Temperature.

In present day systems oil should be fed in accordance with the throttle opening, but with the system just suggested this would not be necessary. It is necessary in present day systems, because the oil between the cylinder walls and the piston is always at so high a temperature that any sudden increase in the temperature caused by the opening of the throttle at once reduces the imprisoned oil to a state whereby it no longer lubricates, with the result that what is known as "drying up" sets in. If the oil round the piston were constantly changing, and free to escape immediately it became heated—if the piston were so shaped as to retain a rather larger supply, and provision were made to be dead certain of it getting there—then we could pour oil through pretty well as fast as we liked, removing the possibility of drying up, and still without the common nuisances that result from over-oiling. These nuisances are to-day present, because the oil not only gets there, but continues to get there, while no provision is made for it to get away. Make this provision, and one can "over-oil" to one's heart's content without experiencing the troubles which are inseparable from such a procedure in present-day engines.

CHINOOK.

The construction of a public highway (the first ever proposed) leading from Guayaquil (Ecuador) into the interior of the country is projected. Commercial experts regard this enterprise as an opening in the future for the sale of motor cycles in this country.

INDUCTION PIPE DESIGN

The Influence of Induction Pipe Design on Ease of Starting and Petrol Consumption.

PRACTICALLY all details of engine design have recently been subject to a thorough threshing out in these pages, and great diversity of opinion on most details has been disclosed. There is, however, one point which is quite an important one in the design of any engine that, so far as I am aware, has not received the consideration it deserves, and this point is the design of the induction pipe.

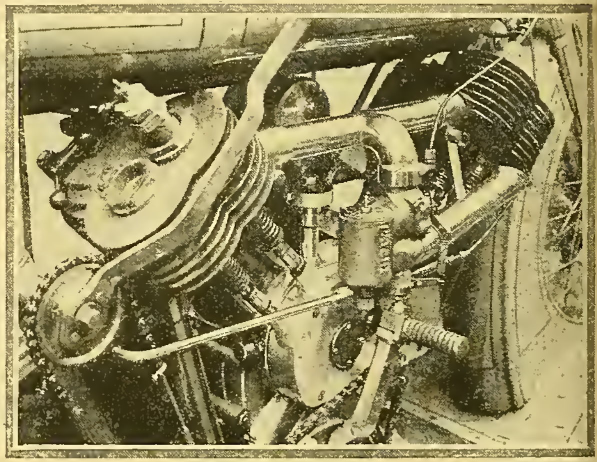
In the case of the single-cylinder machine this pipe is so short that there is no scope left for diversity of design, and, except that one machine may have a pipe slightly longer than another, it may be taken as read that all single-cylinder induction pipes are of one type, and that the design is settled.

The Latent Heat of Evaporation.

In the case of the twin this is, however, an entirely different proposition, and when one considers the important influence that the design of an induction pipe has on the running of an engine, it is surprising that more attention has not been paid to this important matter. The induction pipe determines primarily by its length, but also to some extent by its shape, ease of starting, and the petrol consumption of the machine. Evaporating petrol has a temperature lower than that of the atmosphere when this evaporation takes place, even though at the time the atmosphere may be somewhere round about zero; consequently, when an engine is given the first few revolutions for starting, the evaporation of the petrol at the jet actually cools the carburetter to a lower temperature than that at which it was previously, and if the engine does not start at once this cooling effect very soon takes place along the whole length of the induction pipe. Once the operation has been started it is cumulative in its effect, so that if the engine, for some other reason, happens to be stubborn in starting, the induction pipe is reduced to such a low temperature that any petrol vapour entering it from the carburetter is soon reduced to a state of liquid again, and probably never reaches the engine in the form of gas. If, of course, the engine starts at the first revolution, this cooling effect on the induction pipe has not time to get to work to militate against easy starting, but all the same it has its effect on the running, as will be seen shortly.

Long Induction Pipes.

An obvious question now presents itself. If a long induction pipe is likely to discourage easy starting, how is it that flat twins start so easily, as this type of engine nearly always possesses a long induction pipe? The answer is not so difficult as would at first sight appear, as other circumstances come into operation mainly because high speed is rapidly generated as a result of the outside flywheel, and the first explosion takes place before much condensation has had time to make its presence felt. In the case of V twins, however, this does not apply, and if, for some reason such as faulty ignition or a slight air leak, a V twin does not start very easily, the difficulty in starting in cold weathe will be very much increased in proportion to the lengt of the induction pipe. In warm weather the sam theory applies, naturally, but as the induction pip may have a temperature very much above that of th condensation of petrol, it takes some time before th whole of this heat is taken out of the induction pip by the condensation caused, and unless there is something radically wrong with the engine it should hav started long before serious condensation sets in. Th first explosion in any engine is a step towards th lessening of the condensation in the induction pipe because by heat conductivity the induction pipe i warmed, and this goes on with a continual increase o temperature in the induction pipe until this ha reached its maximum temperature, which, at the engine, will be practically that of the cylinder, but at the carburetter will be something very much lower. Now if the induction pipe is long and the reduction in temperature at the carburetter is serious, it is possible that the temperature may not be maintained sufficiently high to ensure complete evaporation at the high speed at which vaporisation must take place in a normally running motor cycle engine.



The P. and M. 90° twin engine and induction pipe details. According to the ideas of the writer of the accompanying article, the abolition of the elbow would be an improvement, even though it involved the abolition of the hot air pipe.

Wrapping the Induction Pipe.

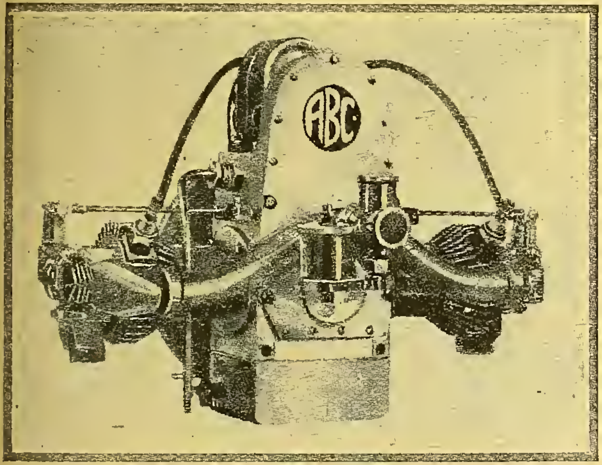
Now, as I have already said, the temperature of evaporation of liquid petrol is always lower than that of the surrounding atmosphere, it will be clear that wrapping a long induction pipe with insulating tape in order to keep it warm rests on fallacious reasoning, for an induction pipe exposed throughout its length to the presence of the air is subject to a warm influence on the outside, which in some measure tends to counteract the cooling influence on the inside. If

nduction Pipe Design.—

he induction pipe is wrapped with some non-conductng material such as insulating tape, the warming nfluence of the air is taken away and the pipe is subected solely to the cooling influence of the evaporatng liquid inside.

If the pipe happens to be made of good heat-conducting materials such as copper or aluminium, which, unfortunately, are used only rarely, this reasoning needs some qualification, for the heat of the cylinder will be conducted along the pipe and will tend to keep the pipe at a higher temperature than that of the atmosphere and consequently to assist vaporisation materially. The value of this reasoning depends, however, on the length of the pipe. If the pipe is a good heat conductor it will certainly get warm near the carburetter sooner than if it were made of a less heat-conducting material. On the other hand, if it is of good heat-conducting material it will also dissipate the heat very rapidly; consequently under these circumstances—*i.e.*, with a copper or an aluminium pipe—wrapping with some non-heat-conducting material should be good practice. It would be possible, however, to have a pipe of such a length—and it is also possible that such pipes are to be found in some present-day engines—that by the time the heat from the cylinders had reached the carburetter along the induction pipe, it would all be taken up by the evaporating petrol, so that the induction pipe at its point of junction with the carburetter might be actually below atmospheric temperature.

Thus a carburetter should be placed as close as possible to the cylinders, or, where a really close position is impossible on account of some point of design as in the case of a flat twin, the induction pipe should be brought to the carburetter by a path as close to the cylinder as possible. Some effort in this direction has been made in the A.B.C. T.T. motor cycle engine, which, of course, is famous for its general high efficiency.



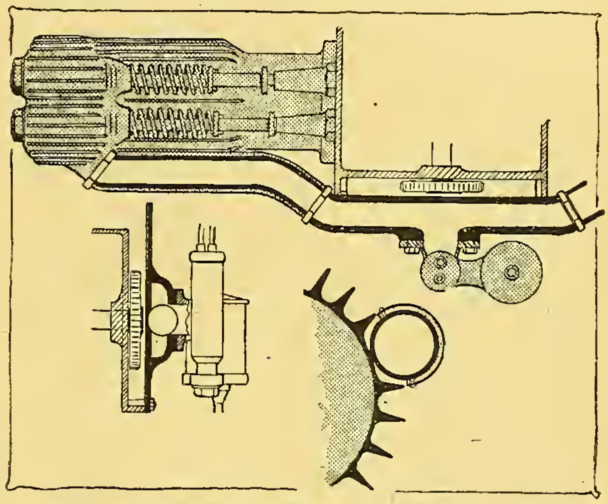
The 1914 T.T. pattern A.B.C. engine. The induction pipe is shorter than in some overhead valve flat twins.

A Suggested Ideal.

The ideal induction pipe design for a flat twin engine, in my opinion, would be a copper pipe from the inlet valve to the carburetter, with one side in contact with the cylinder and the other side, *i.e.*, the side open to the atmosphere, coated with some material or metal of poor heat-conducting properties, such, for instance, as a layer of asbestos, covered with tin for the sake of presenting a neat appearance. This pipe would be very soon heated by the cylinder when the engine was running, and the loss of this heat would be a difficult matter, on account of the asbestos and tin jacket. Starting, of course, would not be facilitated, but economy in petrol consumption would be much increased because there would be no chance of condensation, owing to the too low temperature of the pipe near the carburetter.

Post-war Fuels and the Induction Pipe.

The whole question of induction pipe design is, of course, closely connected with the question of post-war fuels. Most motorists are now reconciled to the fact that after the war, although fuel may be available, it will be very different stuff from that to which they have been accustomed. This point is one that has already received full recognition in America, and the up-to-date and go-ahead American designer is already working on devices for combating this evil when it arrives, and many of his efforts have been directed along the lines of improved induction pipe design.



Plan view of suggested induction pipe design for a flat twin engine. The pipe, which is made of aluminium, is covered on the side exposed to the air with a non-heat-conducting material, while where possible it is kept in actual contact with the cylinder, one of the flanges of which is removed to allow of this being done, as shown in the lower right-hand sketch. The left inset shows how the carburetter is kept as close as possible to the cylinder by the casting of this portion of the induction pipe in one piece with the timing gear cover.

This means, of course, the provision of artificial means of heating the induction pipe. Perhaps the most promising yet put forward is the enclosing of the inlet pipe inside the exhaust pipe, but up to the present this has only been done with four-cylinder engines, and it is doubtful whether it could be done with a motor cycle twin engine. The Henderson, for instance, has the induction and exhaust manifolds cast in one; the carburetter is close to the exhaust manifold, so is directly heated; while the induction pipe, being entirely enclosed by the hot exhaust gases, is always at such a temperature that condensation of petrol vapour would be quite impossible. RAMA.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

CYCLE CARS.

Sir,—May I ask you to take pity on all those individuals who are interested in the simple cycle car? Now that your late contemporary, *The Light Car*, is no more, the whole movement is neglected. Let us have something concerning the simple three and four-wheeler as early as you like.

H. E. MOSS.

THE MOTOR CYCLE TRADE AND THE I.A.E.

Sir,—It was with interest I read in *The Motor Cycle* for May 2nd the article about the I.A.E. I am hoping to see more about the suggestion of including motor cycle engineers as members of the Institution. In peace times I was engaged in the motor cycle business and was an enthusiastic motor cyclist in my spare time. I should like to know what qualifications are necessary to become a member and the way membership is obtained

ARTIFICER, R.N.

TOO TECHNICAL?

Sir,—Little by little "Ixion" reveals himself. We know now that he cannot live in a glass house: we have only to compare "Occasional Comments" for the past year with those of five or six years ago—I know them no further back, alas!—to see this. No longer are we exhorted to drive our speedometers off the magneto sprocket, no longer are we thrilled by his "annual toss," but we are fed on "per b.h.p. hour" and other similar paragraphs. Yet he asks if *The Motor Cycle* is getting too technical! See to thine own house, David!

But, sir, seriously, would it not be possible to have Reminiscences—*à la* "Veteran," a little more often, or to start once more your "Looking Back" page? I enjoy every word of your technical articles, but still I sometimes feel that an article on the good old days would relieve their severity, and I fancy that I am not alone in this.

J. M. PHILPOTT.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—I feel sure there are many, like myself, who thank you for giving prominence to the case of the motor cyclists in the Royal Air Force being classed non-technical. As a motor cyclist myself, and my son a motor cyclist in the R.A.F. in France, I am greatly interested in this matter. Unless this classification is altered I feel sure it will discourage and create discontent amongst this section of the R.A.F. My son, although a motor cyclist, is an expert motorist, and has driven every kind of motor vehicle that is now used in the R.A.F., and there must be many more equally skilled now serving as motor cyclists.

The least the responsible officials can do is to give these men the same rank as the M.T. drivers, or give them the privilege to transfer to the M.T. I hope in the interests of all concerned the authorities will see that these men receive, as you say in your able article, the recognition which is clearly their just due.

A. G. COPELAND

Sir,—The trouble in the R.A.F. is identical with that which prevails in all the departments of the Army where motor cycles are being used. There is no man at the head of affairs that has any practical knowledge of motor cycles. Car men we have in plenty, but practical motor cyclists are conspicuous by their absence.

The regulation which forbids flying cadets riding motor cycles must have been agreed upon by a body of men who have no knowledge of motor cycling. The quickness of decision necessary to success in flying can only be cultivated by either flying practice or motor cycling. Every motor cyclist of experience knows this. Constant flying practice is impossible for cadets, and indeed the enormous expense of such training flights is manifest.

Splendid training for hand, eye, and brain is obtained by motor cycling at an infinite saving of labour, petrol, and time. And yet such motor cycling is forbidden. Why are the R.E. D.R. depots failing to train effective despatch riders? When, oh when, will the powers that be learn that motor cycles (be they employed for motor machine gun work, despatch riding, or any of the hundred departments where their utility has forced their adoption) must be regulated and controlled by highly placed officers who have a practical knowledge of the somewhat complicated machines with which their units are concerned? Wireless telegraphy, gunnery, engineering, all would be hampered and sterilised if placed under the control of men who have no knowledge of these subjects.

We know we are a foolish people who trust to muddle through, but such muddling is criminal. I myself have seen motor bicycles being passed out of the factory for service at the Front by a car man who had never ridden one in his life.

I have written on this subject before without avail, but trust that to-day another letter may do good.

CHARLES S. PATTERSON, M.B., M.R.C.S.
(Late Judge Auto Cycle Union.)

PAVÉ ROADS, BUTT-ENDERS, AND "CRITICISM"!

Sir,—"Tampion," in your issue of May 2nd, says that he would be pleased to see our own road authorities laying down *pavé* roads at home. They have done this fairly thoroughly in South Lancashire and the West Riding, and I can assure "Tampion," after 70,000 miles chiefly on these roads, that they are a perfect nightmare. I could map out a route for a six days' trial in the district lying roughly between Manchester and Leeds which would be an absolute test to destruction, especially of sidecars. If I could choose my roads I would never look at another stretch of *pavé* as long as I live.

With regard to his query about butt-ended tubes, the following may help him. Clean both butt and cup thoroughly with petrol. Smear both *thickly* with cycle solution (not motor cycle, it is too sticky), and then push the butt firmly into the cup. Leave it for about twelve hours—more or less according to the time of year and the general conditions of temperature, etc., and then press down the edges. This makes an absolutely strong endless tube, but if he wants a butt-ender, I am afraid he will not find one that will stand up to hard work. The only one I ever found at all satisfactory was a heavy John Bull, but even that would give out after a ridiculously small mileage—usually miles away from anywhere. If I ever have to buy a butt-ender at a small garage where there is nothing else in stock I always treat it in the above manner at the first opportunity.

May I also endorse "J.G.'s" letter in the same issue. The criticism he mentions has led a large number of my friends to discontinue the paper in question and at the same time to send an annual subscription to *The Motor Cycle*. It seemed to us so petty, so mean, and so unworthy, that the paper became impossible. We noticed, with satisfaction, that you treated it with the contempt it deserved, and I am sure many of your readers will join us in congratulating you, sir, on your silence under what was at times considerable provocation.

PADRE

THE CASE FOR THE LONG STROKE.

Sir,—We read with interest Dr. Lindsay's article in *The Motor Cycle* of March 28th, and would like to point out that, while the speed of 50 m.p.h., which has been attained by a 198 c.c. Levis, is probably a record speed for any two-stroke engine of similar size, we ourselves have considerably exceeded this speed with our 2¾ h.p. 350 c.c. models, on which we attained a speed of 60 m.p.h. in the 1914 Junior T.T. BUTTERFIELDS, LTD.

REMOVING THE CONTACT BREAKER.

Sir,—I have always understood that the contact breaker of the magneto of a 2¾ h.p. Douglas could not be removed without first taking off the flywheel, and I believe the makers say so in their handbook of this machine. My present Douglas (1915) has a Thomson-Bennett magneto, and I succeeded a few days ago in removing the contact breaker without disturbing either the flywheel or any other part of the magneto.

I proceeded thus: I unscrewed the screw attaching the contact breaker to the armature, and drew it out until it touched the flywheel. I then prised out the contact breaker until it was clear of the armature, and tilted it, when, of course, the screw could be taken out without any difficulty. The contact breaker itself could then be removed quite easily.

The Bosch magneto is similar to the Thomson-Bennett, so that this method will probably apply to it also, but I have not seen the E.I.C. and the Dixie, so I cannot say whether it is applicable to them or not.

The above method is so obvious that I cannot help thinking that it must be well known to Douglas riders.

J. H. DEWAR.

MAGNETO DESIGN.

Sir,—I have read with much interest the article on "A New Two-stroke V Twin Engine" in your issue of April 25th, and I think the designer is to be congratulated on what you term the fertility of his brain. I should like to offer one or two criticisms on the proposed ignition system.

1. The inductor should move rapidly into or out of the lines of force in order to obtain a high e.m.f. (It is not the number of lines of force that counts, but the *rate* at which this number changes.) As the piston is just nearing the top of its stroke it is moving comparatively slowly; consequently, the rate of change of the number of lines of force, and therefore the e.m.f., is small.

2. The magnetic circuit is too long. The primary winding of the coil being short-circuited during a portion of its time has a demagnetising effect on the magnetic circuit, and the lines of force, instead of passing through the core of the coil, would tend to pass through the lower part of the cylinder unless the inlet port was made abnormally wide.

3. Great difficulty would be experienced in making the contact breaker work magnetically, since the maximum number of lines of force depends on the speed, and this is variable. It is true that the spark would be advanced automatically as the speed increased, but it is improbable that the "advance" would be just enough and no more.

Again, owing to the vibration of the engine, certainty of operation with a given number of lines of force is doubtful.

4. Presumably, this alternative system is only intended to apply to single-cylinder machines. WILBUR.

Sir,—The ignition device fitted to the twin two-stroke engine described in your issue of April 25th is both interesting and ingenious, but for several reasons I do not think it would be as efficient as the rotary type of magneto.

The chief drawback, in my opinion, is the very low speed at which the lines of force would be cut, as when the inductor passes through the magnetic path the piston speed would be practically at its minimum value. With the engine running at 1,000 r.p.m. the mean piston speed would be roughly 400ft. per minute; the speed, of course, would rise from zero to 650ft. per minute, and back to zero every half revolution. A magneto with a 1½in. diameter armature running at engine speed (1,000 r.p.m.) would have a peripheral speed of about 390ft. per minute, or, practically, the same speed as the mean velocity of the piston. The piston speed at the moment the lines of force are cut would be far below this figure. Therefore, not nearly such a good spark would be obtained as with a rotary magneto.

The heat of the cylinder would probably have a very deleterious effect on the permanent magnet incorporated with the design; demagnetisation would probably be frequently experienced; also, the reluctance of iron increases with the temperature.

The high temperature to which the windings would be subjected would be unhealthy, but this, possibly, could be overcome by careful design. The maximum safe temperature for cotton insulation is, I think, about 173° F.

Undue simplicity is probably not desirable. The designer of the first internal-combustion engine probably was highly pleased when he designed the automatic inlet valve, and congratulated himself on having rendered his engine much less complicated. So he did: but he rendered his engine far less efficient. ENGINEER.

Batley.

PETROL FOR MUNITION WORKERS.

Sir,—In reference to the letter of "D.R., R.E.," of the 25th April, I do not wish to dispute who has the more right to the use of petrol for joy riding—soldiers on leave or civilians. It is only natural for the soldier to have the first consideration, but why assert that should the munitioner feel tired he go on strike?

I am one of thousands working in the Midlands, who, since the commencement of hostilities, have continuously worked 11¾ hours daily, and there are also those whose health has been seriously affected through excessive overtime, and they have not been on strike.

I hope that Mr. Churchill's statement in the Commons that the work accomplished during the Easter holiday has more than compensated for the time lost through disputes for a whole year, has come to the notice of "D.R., R.E."

If in the near future there is a quantity of petrol to spare, by all means let the munitioner have two or three months' joy riding—if you prefer to call it by this name.

GEORGE BLICK.

GARAGE CHARGES.

Sir,—As in the good old days we were respectively private owner and garage proprietor, your article on garage charges (April 18th) has been read by us with somewhat mixed feelings.

In common with many others, we fully realise the desirability of cheap storage in and around large cities, but, at the same time, there are two sides to the question.

You regard the matter from the aspect of floor space only, whereas, so far as the garage proprietor is concerned, this is almost a minor consideration. Did the average owner merely wheel or drive his machine into its allotted position matters would be simple indeed; but he is by no means so modest in his demands.

Should his tyres require inflating or his generator need cleaning out and refilling he does not hesitate to requisition the services of the nearest garage hand, and minor details soon absorb an amount of *time* which is by no means covered by the sum charged for garage.

He will use the nearest bench and vice, and, in spite of notices to the contrary, walk into the workshop and use whatever hand tools he requires, the said tools being frequently left in the sidecar. He, in many cases, endeavours to execute his own repairs and overhauls, expecting to receive help and advice whenever he gets into difficulties, which he often does at an early stage of the process.

A suggestion of payment for such services rendered, even if couched in the softest language, pointing out that he pays for garage only and not for use of tools and men's time, is invariably met by black looks and indignant threats to transfer his custom elsewhere—often to the great relief of the garage owner.

Taking all things into consideration, it is far from strange that the average garage owner is loth to lay himself out to cater for the sidecar and motor cycle owner, as even if a charge of 2s. 6d. to 3s. per week is made he usually stands to lose over the transaction.

As we stated in the beginning of this letter we fully realise the need for garaging at a low cost, and these remarks are not made in any spirit of meanness or antagonism to the class of owner in question; but, in common fairness, it should be borne in mind that the much abused garage owner has to make his living out of the business, however keen he may be on giving satisfaction to his customers.

We are fully aware that there are many riders who are not as portrayed, and with whom it is a pleasure to deal.

B.E.F. TWO LOOTS, R.A.F.

CARBURETTER ADJUSTMENT.

Sir,—In your issue of April 11th you printed a letter from me on "Carburetter Adjustment." Lest this should have given anyone a bad impression of the carburetter, I should like to say that, having carefully cured all air leaks in the induction system and valve caps, etc., and raised the petrol level in the float-chamber, the machine runs splendidly on jets 000, 3, and 7, giving a tick over, fierce acceleration, and ample power on hills. I do not agree with "Binker" that this is a difficult carburetter to adjust, provided one's engine is in order; I had no trouble once I made the above adjustments.

GEORGE B. AITKENS.

Sir,—With reference to the Binks three-jet carburetter, I have carried out several tests with this instrument (which was lent to me) on my 2½ h.p. Excelsior-Villiers two-stroke, but, like several of your correspondents, could not get anything near the results claimed for it.

After several short journeys at different settings, I took the machine to my favorite test ground (a run on the level and a good hill at the end). I took my old Amac and the Binks carburetters to test them fairly side by side, with these results:

Amac—26 jet (compression tap in carburetter body to introduce extra air). Highest speed, 41 m.p.h.; slowest, at the top of the hill, 8½ m.p.h. Petrol consumption, 92 m.p.g.

Binks—00 jet, 2, 5. Highest speed, 42½ m.p.h.; slowest, 9 m.p.h. Petrol consumption, 67 m.p.g.

Binks—00 jet, 1, 2. Highest speed, 36 m.p.h.; slowest, 8 m.p.h. Petrol consumption, 97 m.p.g.

The Amac setting was the same as that used for 870 miles, at average of 98 m.p.g. The Binks settings are the best of seven. In all cases there was a choking period between the pilot and the main jets. The figures were very carefully taken. The only advantage I found was that the engine would two-stroke at lower speeds with the Binks than with the Amac.

I think other readers' experiences would be interesting. I have tested five different carburetters, but cannot get one to equal the Amac for good all-round results.

I am thinking of fitting a light sidecar to this machine, and should be glad to have readers' experiences with a similar combination. What top gear used (I have a two-speed countershaft gear box), size of jet, general running, and if satisfactory? I only wish to carry a light passenger.

King's Heath. EXCELSIOR.

LOW V. HIGH GEARS: A SOLUTION.

Sir,—The top gear of 3¼ to 1 mentioned by "Four Crazy" appears to be about right, taking into account that his engine is 1,000 c.c., and has a low compression, that he rides solo, and is not too much troubled by running costs, fuel consumption, or any other restriction.

Will "Ixion" please note that I cited him as an apostle of high road speeds, not of high gears? I agree that higher speed is desirable in the case he mentions, namely, "dull stretches of road traversed for the umpteenth time," and also in a few other cases.

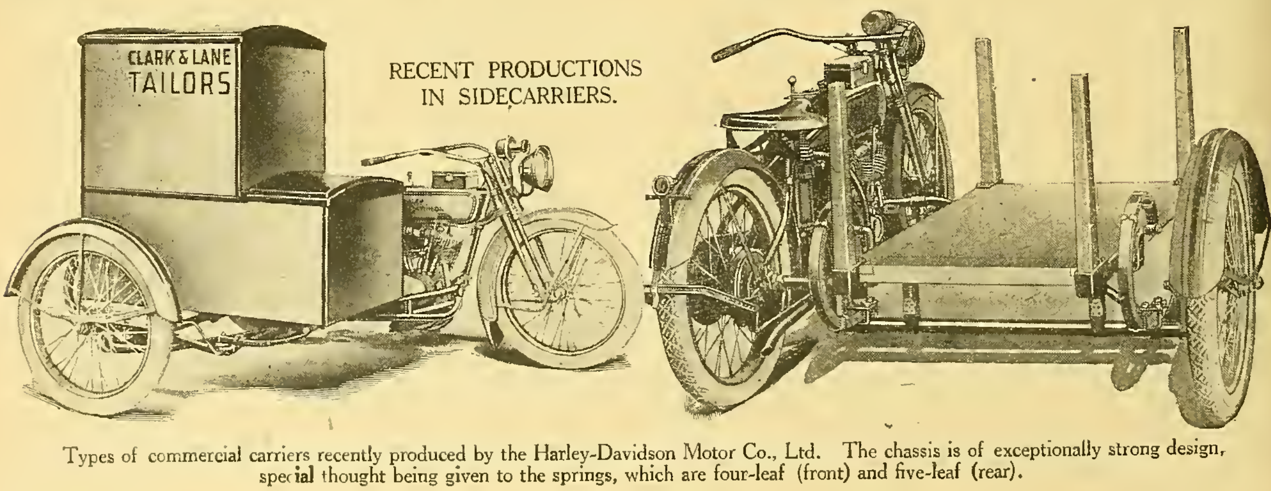
But I submit that ordinary riders are not *blasé*, that they are mostly owners of 3½ h.p. combinations or travel under conditions approximating thereto in power to weight ratio, and that my second-hand 'bus fully loaded could do 37 to 38 m.p.h. on the level (engine revs. 3,000) with a 6 to 1 gear, even when tuned for economy. The motor cycle has passed into a sphere of utility when it replaces railways on a holiday, and should be geared to suit. What is the sense of worrying along for three-fourths of the time to an accompaniment of alternate konks and deafening rattle divided by the petulant jerks of too frequent gear changing, and hoping for that open smooth stretch of road which, when found, is probably spoilt by a stiff head wind?

That part of my letter giving a solution acceptable to all seems to have been obscured by the title, "The makers could cater for both classes by providing a four-speed gear with direct drive on the two higher ratios." I recognise the conditions mentioned in your editorial, but I believe that (1) *most* riders like to climb reasonable inclines on a direct gear; (2) results of 20 m.p.h. average and 100 m.p.g. are good enough for most; (3) the "mean state" represented by one top gear ratio of about 5 to 1 gives satisfaction to few who would not be better pleased with two direct gears of about 4½ and 6 to 1.

"Ixion's" solution of a choice of sprockets is then not enough. I have five engine sprockets, but two cannot be in use at the same time. A four-speed gear with the third speed direct would suit us, but would not appeal to the fast rider. So I venture to propose two direct top gears which could be obtained by one method as follows: Dogs operated by the left foot to engage either of two chains running from the engine-shaft to a two-speed countershaft gear operated by the right foot, with multi-plate clutch inside the two large chain sprockets worked by Bowden cable to lever on the left handle-bar.

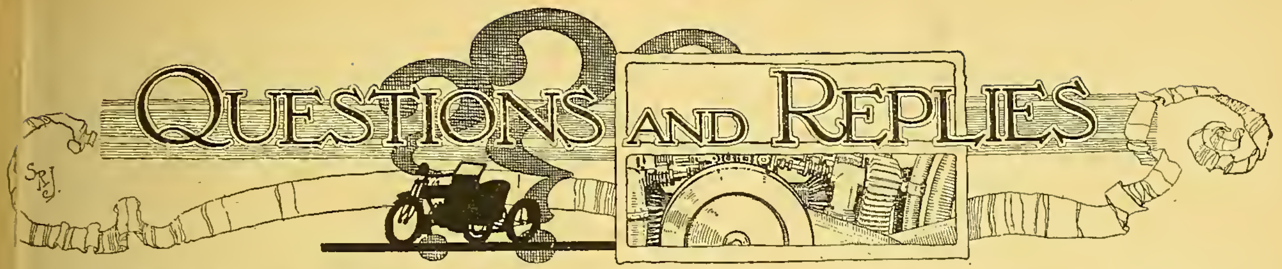
Having gone so far I may as well finish. Valve lifter on the right handle-bar; back and front brakes (belt rim pattern) applied by foot levers on right and left sides respectively with ratchets to hold them; rear chain on the right-hand side, and all chains totally enclosed and ⅝in. × ⅜in.; 80×120 (600 c.c.), two-stroke single, with outside flywheel between chains and crank case; Velocette lubrication; two side-by-side valves as in present four strokes, but inlet opening to be the same as exhaust; two exhaust pipes; the two valves to be worked simultaneously as exhaust valves by one cam on main shaft; magneto coupled directly to extension of the latter on the right-hand side; flat top piston; plug in centre of cylinder head; usual two-stroke inlet and transfer port arrangements; tank, two and a half gallons, for petrol only; very light sidecar body on aeroplane fuselage lines, without door; 710×85 mm. Palmer light car tyres; gear of 6 to 1, modified to suit slower revolution engine. W. R. DEUCHAR, SEC.-LT. R.E.

[*A number of interesting letters are unavoidably held over.* —ED.]



RECENT PRODUCTIONS IN SIDECARRIERS.

Types of commercial carriers recently produced by the Harley-Davidson Motor Co., Ltd. The chassis is of exceptionally strong design, special thought being given to the springs, which are four-leaf (front) and five-leaf (rear).



QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects

Storing Inner Tubes.

? I shall be glad if you will please tell me which is the best way of taking care of spare inner tubes. I may explain that I have airy, dry, cool rooms, nd an airy cellar, which is dry, for cellar, but I am not sure if I should et the air have free access to the ubes or if I should shut them up in box with French chalk well dusted ver them.—Hansom Cab.

e best way is to store the tubes in a dark, cool place, or you may pack m in a box full of French chalk. It most desirable to keep them from ht and from a warm, dry atmosphere.

Armstrong Gears.

? I have two motor cycles with gears out of order, and should be glad of your opinion as to the cause of the trouble. (1.) Mark VI. gear. These gears were taken down by a local mechanic and I sent them away to experts, who returned them guaranteed in perfect condition. I cannot now get them fixed up. There is play in the hub case of approximately $\frac{1}{8}$in. to $\frac{3}{16}$in. The cones are turned up as far as they will go. Would an adjustment of the left cone before putting this gear in assist, or, if so, would balls of $\frac{3}{16}$in. instead of $\frac{5}{16}$in. in the right clutch ball race account for it? (2.) Mark III. These gears apparently worked all right until the push rod was taken out. The push rod, with strong spring, screws into the axle key. Now it will not move into the high gear forward lever position. Has the push rod been screwed up too far, or not far enough, or, in either case, would this affect it? Otherwise, what is the probable cause of the trouble? The gears have been well washed out with paraffin and well oiled. (3.) New Hudson belt rim. This is slightly bent and out of line. Can it be straightened up?—M.J.

1.) The trouble is apparently caused by ncorrect adjustment of the cones. The ight-hand cone should be slackened and he left-hand cone adjusted so that there s a minimum amount of play in the belt drum. The wheel is then adjusted by the right cone, and we think this would cure the trouble. In any case, it would be useless fitting other balls of different size in the gear. The correct size balls are: Belt rim side—Outside cone, $\frac{5}{16}$in.; round driver, $\frac{1}{4}$in.; inside of driver support, $\frac{3}{16}$in.; other side—One row, $\frac{5}{16}$in.; underneath clutch body, $\frac{3}{16}$in.; clutch fork, $\frac{1}{4}$in. (2.) Either the push rod is screwed in too far, the spring round the push rod is too long, or the spring in the case on the gear control rod is too weak. (3.) This might be straightened up by a good local repairer at your own risk.

Misfiring.

? I should be much obliged if you could suggest the reason for the following trouble: My mount is a 5-6 h.p. 1914 Clyno combination in first-class condition. The trouble is constant misfiring in the front cylinder—not due to ignition, or plugs, or air leaks. Spasmodic misfiring occurs when the engine is run slowly in neutral, but is not often noticed when travelling slowly on the road, and not at all in either case at higher speeds. There is a $\frac{1}{16}$in. gap between the tappet and inlet valve stem of the front cylinder, as the valve timing is a trifle early. The only reason I can think of is that the piston rings may be broken or stuck, and that the front cylinder is not exerting full suction on the inlet stroke. The compression in the front cylinder is considerably less than in the back, and I think this points to the above being the case. All the valves have been ground in recently, and I do not think there can be much at fault.—E.S.W.

In spite of your opinion to the contrary, we are inclined to think that the trouble is probably due to an air leak at the front cylinder induction pipe union. Also, one of the piston rings may be stuck or broken. A sixteenth of an inch gap between the tappet and inlet valve stem is far too much. The clearance should be about the thickness of the blue cover of *The Motor Cycle.* All valves should have practically the same clearance, and it is just possible that the extra clearance at one cylinder may partly account for your trouble.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD

Carburetter Flooding and Extraordinary Petrol Phenomenon.

? My machine is a 5 h.p. Indian, and I have been troubled for a considerable time by petrol flowing out of the air intake when the engine is running. The level is subnormal, and the inlet valves are in adjustment, and there is no leak at the float chamber needle valve. I should be greatly obliged if you would give an explanation of this curious leakage, as there is no sign of leakage when the engine is not running. By the way, I came across an amusing article the other day by "Road Rider," where he mentions lighting war time petrol with a detonator. As I wanted to imitate an H.E. shell exploding, for a stunt we were having, I put a fulminate detonator in a "petrol-tight" tobacco tin and filled it with petrol. I lit the time fuse and waited for a bang, a large sheet of flame, and a lot of black smoke. The detonator went off, blew the tin to pieces, but the petrol did not light!—R.F.A.

Either the valve requires grinding in or the level is still too high. The petrol should come to within $\frac{1}{16}$in. of the top of the jet. The level may be reduced by bending down the arms on which the float is suspended. If there is grit underneath the valve it need not be ground in, but should be merely tapped occasionally and sometimes turned round on its seating, when the grit will be displaced. The reason why the petrol did not explode may have been due to the fact that the mixture of air and vapour was not correct. It seems to be quite extraordinary that it did not light. This, again, may have been due to the fact that the mixture was incorrect, or the petrol may have been of very poor quality. Another possible explanation is that the fulminate of mercury explosion flame was not hot enough to light the petrol, and that the petrol was blown away before it had time to light

RECOMMENDED ROUTE.

Luton to Manchester.—P.K.

If you do not object to a few hills, we recommend *(a)*, but *(b)* is more level. *(a)* Luton, Dunstable, Woburn, Newport Pagnell, Northampton, Market Harborough, Leicester, Loughborough, Derby, Matlock, Bakewell, Buxton, Stockport, Manchester. *(b)* Luton, Dunstable, Fenny Stratford, Towcester, Daventry, Coventry, Lichfield, Rugeley, Stone, Newcastle-under-Lyme, Congleton, Alderley Edge, Cheadle, Manchester.

Office Removal.

Messrs. Hans Renold, Ltd., inform us that their London office is being moved to Bush Lane Chambers, Cannon Street, E.C.4, owing to the fact that the Air Board has taken over their former premises in Kingsway.

Opening of a New Depot.

We are informed by Messrs. S. Smith and Sons, Ltd., 179-185, Great Portland Street, London, W.1, that they have opened a depôt at 12, Jackson's Row, Deansgate, Manchester, news which will doubtless interest our northern readers. The premises will carry a large stock of Messrs. Smith's specialities, and will be a distributing centre for Lancashire and Yorkshire.

Industrial Reorganisation in the Tyre World.

Messrs. W. and A. Bates, Ltd., the manufacturers of John Bull tyres, etc., of St. Mary's Mills, Leicester, have taken a departure that should have considerable interest to all those concerned in post-war questions for industrial resettlement. Briefly, the scheme of Messrs. W. and A. Bates is one to effect the co-ordination of employees with the employers. The whole scheme has been worked out between the proprietors of the firm and representatives from the employees, and is now in operation, and is fully dealt with in an effectively got up booklet recently published by this tyre and belt-making firm.

There have, of course, been many suggestions made in various quarters that some such scheme as this is the key to the solution of all future labour difficulties, and there is no doubt that many firms are anticipating the official creation of some such system to meet the post-war situation.

We understand that Messrs. W. and A. Bates are quite willing to give information concerning the working of their scheme to anyone interested, with the idea that their experience may be of value to any later experimenters on the lines of the Whitley Report.

Catalogues Received.

Pedley Tyres and Belts. J. Pedley and Son, Ltd., Oxford Works, Great Charles Street, Birmingham. Export catalogue. This catalogue is got out for circulation amongst Messrs. Pedley's customers abroad, and is interesting as showing the enterprise of this firm in publishing weights and measurements for export in English figures and in the decimal system. For example, fifty heavy motor cycle covers and tubes in medium sizes can be packed into an export case of the following dimensions: 34×34×48in., occupying 32 cubic feet, the metric equivalents, which are given, being 864×865×1,220 mm., or .910 cubic metre.

Clincher London Premises Commandeered.

Once more the Government have found it necessary to "take possession" of an important block of business buildings and leave the ex-tenants to find a new home. It is but a week or two since the Air Board took over half of Kingsway, and to-day we learn that the North British Rubber Co.'s Great Portland Street premises have been chosen as a home for a further Government extension, and the present occupants have to find a new location at very short notice. The new address of the London tyre department will be 111-113, Great Titchfield Street, Oxford Street, W., while the export department, advertising and general manager's London office will be situated at 257-259, Oxford Street, close to Oxford Circus. Traders, exporters, etc., are requested to please note.

Enamelling Outfits.

Messrs. Jenson and Nicholson, L Stratford, London, E.15, have decidec supply complete enamelling outfits for owners and motor cyclists. These ou contain all the materials necessary renovate a car or motor cycle and sid completely.

New Hardening Process.

Those interested in the heat treatm of steels and in the use of what conventionally described as "new steel would do well to communicate w Messrs. Darwin and Milner, Ltd., Messrs. Sybry, Searls, and Co., Lt both of Sheffield, for particulars of th "Pyreks heat indicator compoun This is an invention of the originator Cobaltcrom steel, and is claimed to as simple and reliable in use as, a much cheaper to install than, any py meter installation.

The Wood-Milne Tyre Pump.

The Wood-Milne pump is a very use accessory for all owners of motor ca but, owing to its size and somewhat hi price, it is not largely used by mo cyclists. However, those motor owners who are using motor cycles order to economise in petrol will find t excellent foot pump to be still a ve useful garage accessory, fitted with adapter for motor cycle tyre valves. T pump, since it is worked by the foot, w originally designed to overcome t fatigue attendant on tyre inflation means of an ordinary hand tyre pum and the amount of labour saved pumping up a 650 × 65 tyre is perfect ridiculous in comparison with the ener which would have to be exerted to pun up the same tyre by means of an ordina motor cycle inflator. During the war t pump is being used to a large extent engineers' shops, for forced lubricati and testing, for inflating air beds hospitals, for testing radiators and tan after repair, and a host of other purpos for which Messrs. Wood-Milne Co., 2 Albion Street, Gaythorn, Mancheste have adapted it.

* * *

FOR OWNERS OF WATER-COOLED ENGINES.

ALTHOUGH the majority of motor cyclists are riders of air-cooled machines, there are, nevertheless, a goodly number of owners of the water-cooled type. To these anything that can possibly improve the efficiency of the engine circulating and cooling system should be a boon and a blessing. The average motor cycle water-cooling system really needs more attention and care than that of the normal car, as everything is made on a much smaller scale.

The smallness of the parts in the case of motor cycles makes the system far more liable to the main trouble that besets all water-cooling arrangements—the trouble of choked radiators as a result of "furring." "Fur," or the rust-like deposit that forms inside any container in which impure water is frequently heated (*e.g.*, in a kettle, boiler, or cylinder jacket), has a dangerous capacity for choking up any passages through which water may have to flow, and if its formation is allowed to go on unchecked the whole circulation in such a system as that found on a motor cycle soon becomes inoperative, or at least highly inefficient.

Experiments have been made to provide some preparation that will prevent the formation of this deposit and will remove it once it is formed, but, so far, as we are aware, the only effort that has met with unqualified success is that of Messrs. Boilerine, Ltd., of 885A to 897, Old Kent Road, S.E.15. The product of this firm is known as Boilerine tablets, which are sold in tins containing 200, 450, or 1,000 tablets.

Clearing out "Fur."

While primarily intended to prevent furring up of radiators, the tablets are certainly efficacious in clearing out deposit already formed, as we have proved by our own experience. A radiator in our possession, much given to boiling when in use, has entirely given up this obje tionable trouble after three applications twenty tablets each to fresh water in th radiator. Incidentally, a slight leak ha also stopped, though there is nothing i the claims put forward for the preparatio that could lead one to expect this resul

To anyone troubled with radiator in efficiency, we have not the slightes hesitation in cordially recommendin Boilerine. The makers of the preparatio are also willing to test for hardness, with out charge, any water sent to them s that motorists may know just what "the are up against" as regards the coolin arrangements of their machines. Thi knowledge should be of the greatest us to all, as early recognition of the rea strength of one's enemy is half th battle won.

A very interesting booklet entitle "What Goes on in your Radiator," ma be had on application to Messrs. Boilerine Limited.

RIDER TROWARD & CO.

Our advertisement bill for the last three years has averaged something like a quarter of our total capital each year, and we have often been asked, "Does Advertising Pay?" Our answer is most emphatically "Yes, if it is gone about in the right fashion." Let us tell you why we advertise so freely, so that you may judge for yourself if results justify the expense. When we advertise, we have three leading rules always before us:

1. We first try to make our advertisement such as the reader will **see** it, and, having **seen** it, will not pass it by, but **will read it** to the end. An advertisement seen in passing, and not studied, is waste of time and energy.
2. We then state reasons **why** the reader should deal with us, rather than with any other firm—why we are, in our opinion, the best firm to deal with—and we seek to impress on the reader any special points in our favour which do not apply to other firms. This point is the second in importance.
3. We then tell the reader **what** we have to sell. An attractive advertisement telling you why you should purchase from us, and not stating what we have to sell, is again mere waste. And in stating what we have to sell, **we do not include goods** which we can only obtain to order, or which are **not ready** for immediate sale. Everything advertised by us is **ready for delivery.**

Now that we have told you why we advertise, and what we advertise, you will be interested enough to read all we have to say. As, however, we try to say the most possible in the smallest space, we ask you to write for fuller details of our terms of business, and as we cannot advertise our Stock of 200 Machines in the space at our disposal, we ask you to write for full list. The points of our dealings that we would impress upon you are as follow:

(*a*) We sell any machine by instalments—quarter down, balance to suit customer—provided that the machine remains in our possession till paid for. Thus a good mount can be obtained now, and paid for gradually, and be quite ready for use the moment the War ends. REMEMBER THAT EVERY MORNING YOU WAKE UP THE END OF THE WAR IS A DAY NEARER.

(*b*) We can now book orders for the best makes of Motor Cycles after the War, and, in the majority of cases, can promise early delivery. We only require a £5 deposit for any make of machine.

(*c*) We can accept War Stock to any quantity in payment. Thus you can at the same time help your country and help us.

(*d*) If you require any rare make of machine getting that is not in our lists, we can always obtain in a reasonable time.

(*e*) We can accept your old mount in part payment, either for another machine for immediate use, or as part payment for a new machine for delivery after the War. In the latter case you obtain full benefit of the present market prices, however long the War may last.

(*f*) If you purchase a Second-hand Machine from us, it is guaranteed. In addition to this, even if—though the machine is mechanically perfect—you do not like it, and wish you had bought something else, we will exchange, entirely free of charge, within three weeks of purchase.

(*g*) We will sell your old machine on commission, if you are not requiring another one now, and will make no charge if no sale results. On sales we charge 5% commission.

Now that we have told you **what** we can do for you, we give you a selection of **what** we can sell you. Your enquiry will have prompt and courteous attention, and we hope to hear from you.

SELECTION FROM STOCK:

1.	**ALLON,** 1916, 2-speed, 2-stroke	27 gns.
2.	**ALLON,** 1917, 2-speed, clutch, run 250 miles only	36 gns.
3.	**A.J.S.,** 1915, 2½ h.p., clutch, kick-starter, 2-speed	39 gns.

IMPORTANT NOTICE.

Owing to the Whitsun Holidays, the issue of "The Motor Cycle" for May 23rd, must be closed for press earlier than usual. All copy and instructions for Miscellaneous Advertisements in that issue must, therefore, be in our hands not later than first post on Thursday, May 16th.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the production of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

The Decimal System.

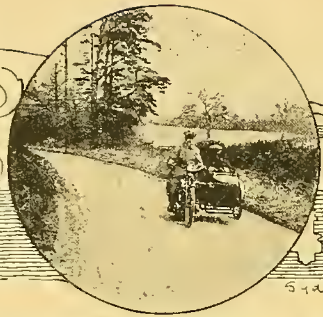
THE decimal or metric system, which means counting by tens, thus doing away with our absurd coinage, weights, and measures, may be possibly adopted in this country. It is a system not unknown to our readers, as, since the internal combustion engine originally came from our great and noble Ally France, it has always been customary to reckon the bores, strokes, and cubical capacities in the metric style. Only a few conservative motor cycle engineers have attempted to describe engine sizes in inches, and when they have done so they have conveyed so little meaning to our readers that in "Buyers' Guides" all dimensions have been given in mm. The statement that an engine has a bore of 90 mm. has a clear meaning to the average motor cyclist, far clearer, we venture to think, than its approximate equivalent in inches, for we are already accustomed to the use of the metric system in this connection.

Though the system came into force after the French Revolution, the famous British engineer James Watt laid down a plan seven years before which very clearly resembled the French scheme. We can all remember in the days of our youth how much time and how many tears were shed over learning our weights and measures and doing compound sums, and with what relief we were moved on from fractions and decimals. This is what the adoption of the metric system would mean—the scrapping of all tables, the abolition of compound sums, the general simplification of commercial and industrial arithmetic, and the bringing into practice of a practically universal system of reckoning which would improve the foreign trade which is to help us to recover from the effects of this terrible war.

So far we have dealt with the matter only in so far as engine measurements are concerned, but if the system is used in the making of our motor cycles it must also be used in paying for them. The metric system, therefore, would be introduced into coinage as well. What most experts who are working on the scheme seem to have forgotten is that it is most essential to retain the names of the old coins; even in France the five centimes piece is still called the *sou*. They agree to retain the sovereign and its tenth part the florin, but they call the shilling a half-florin, and the sixpence a quarter-florin, and in our humble opinion they go off the mark altogether when they get below this coin, as they divide the sovereign into 1,000 parts, each of which is called a mil—a name quite unknown. Would it not be better to copy Continental practice, let the shilling remain as it is and make ten pennies go to the shilling by raising the value of the penny? Then introduce a new small coin, the English cent, which would be the English *centime*, or, since it would be our smallest coin, the old name farthing could be retained. Of these ten would go to the penny, five to the halfpenny, and 100 to the shilling. If smaller coins were needed to subdivide the penny, which would be nickel, bronze cent and two-cent pieces could be used.

It is quite impossible in such a short article to do justice to the metric system, but we may conclude by saying that if adopted it would benefit the whole country by increasing our export business and by simplifying calculation in all trades and industries. There are objections against it, and pretty powerful objections too, but so there are against the most beneficial innovations. We have only to consider the daylight saving scheme, which was laughed to scorn before the war, but which has since been found to have been of inestimable service to the country, and we think we have but few readers who, when peace reigns on earth once more, will not be glad to enjoy those precious hours of daylight on their motor cycles during the long summer evenings.

Those who are interested in the metric system should apply for interesting literature on the subject to the Decimal Association, Finsbury Court, Finsbury Pavement, London, E.C.1.



An Infinitely Variable Change Speed.

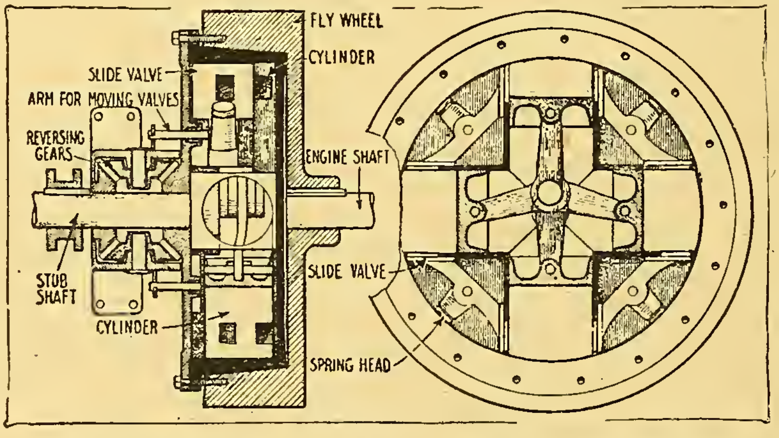
An Article describing a Simple Form of Hydraulic Transmission.

THE infinitely variable gearless change speed has been an inventor's ideal ever since motor vehicles were permitted to run on the English roads, and for this reason the friction transmission has received a great deal of attention both by car and motor cycle designers.

There is another form of infinitely variable change speed—the hydraulic clutch—of which one type is illustrated here. This is an invention intended to replace the clutch of a car, but, excepting the embodiment of a reversing gear, the same application of hydraulics could be utilised on a motor cycle. The entire device occupies but a little more space than the internal part of the standard clutch, which it displaces, as no friction clutch is necessary with this invention.

The drawings give a comprehensive view of the device, as all of the elements are shown in the two views. The body of the device is a cylindrical shell, the perimeter of which fits the standard clutch element inside the flywheel. This is held in place either by friction or by means of capscrews, so that it is permanently fixed to the wheel.

The rear side of the shell has a removable plate, to which the mechanism for changing the speed is secured on the inner surface. Within the shell are four radially-disposed cylinders, each cylinder having within it a piston, suitably packed with rings, following the usual practice. The stub-shaft, which enters the rear plate of the shell, has a single crank to which the four connecting rods are secured, so that the pistons have a successive motion to and fro as the shell turns.



An interesting hydraulic transmission system replacing the clutch, and providing an infinitely variable gear ratio.

The head, or outer end, of each cylinder has ports on two opposite sides, the outer surface of each cylinder, along the ports, being planed flat and covered by slide valves, which move axially, or parallel with the stubshaft. The valves are L-shaped, and provided with suitable openings to co-ordinate with the ports of the cylinders, each valve being designed to open or close the ports of two adjoining cylinde To effect this, each L-valve has a stem that pass through the removable plate of the shell, the ou ends of these stems being rigidly attached to a r which, although it turns with the shell, is neverthele easily adapted to connect with an operating lever.

It is obvious that, as the cylinders are rigi attached to the shell, the stubshaft will not tu if oil be permitted to pass freely in and out the cylinders. The only effect in such a case wou be to produce a reciprocating motion of the pisto When, however, the driver of the car moves forwa the lever the L-valves are caused to travel inward and the ports of the cylinder are closed, the pisto are restricted in their reciprocal motions, and t shaft turns, the rate of speed, relatively to the engi speed, being dependent on the quantity of oil which displaced at ea revolution. If t ports are entire closed, then t stubshaft will tra at the same rate speed as the engi shaft.

It is claimed th there is no appre able loss of pow and the sligl amount of oil whi escapes past t valves imparts resiliency, or fle bility, comparat to the electric magnetic driv If employed for motor cycle the would not be a single gear wheel in the mechanis

In hydraulic systems the cases containing t mechanism must be entirely filled with oil, or with t liquid used to provide the transmission. In t invention the pistons are just as effective if the sh is half filled, for the reason that the ports are at t outer ends of the cylinders, and as the shell revolv the oil is thrown outwardly by centrifugal force, that the ports are always submerged in oil a are capable of taking a full charge without drawi in air.

Fully half of the cubical contents of the shell m be devoted to air, or a partial vacuum may be form therein, thus taking care of any undue expansion.

OCCASIONAL COMMENTS

BY "IXION"

The Cycle Car Coming.

I HAVE repeatedly asserted in this column that aero engine practice has rendered a good cycle car possible, but that the reluctance of directors to br k out a new policy still renders the production of a ıss vehicle by a class firm improbable. A designer w se big cars are famous all the world over writes to orrect me. His post-war cycle car is already in e tence, so far as the parts and their individual tests ar concerned. Road tests of the complete chassis ar about to commence. The vehicle is in no sense c ventional, and is designed to compete with the side o it de luxe so far as price and road performances a concerned.

A Four-cylinder Caveat.

I WONDER if the riders who try to "boost" the four-cylinder realise that the overhaul of its bearings requires considerably more skill than a si ilar job with a simpler engine, and that the cost is i proportion. Similar reasoning applies to spare p ts. The cost of material is trivial, where the small d ails of motor cycle engines are concerned: and the c t is based on labour, including actual machining, s rekeeping, etc. For example, there is practically n difference between the cost of a new piston ring f a Wall Auto-wheel engine and one for a 260 h.p. rcédès. So the piston ring bill included in the c rhaul of a single-cylinder engine may be three or f r shillings, but for a four-cylinder it will approach sovereign. Other parts are multiplied in the same io, and where the number of parts is the same in h cases, *e.g.*, a crankshaft, the cost does not remain ual. Now motor cycling is a sport with a very rrow cost range, so far as the user is concerned. ly a very marked technical and practical superiority ll persuade motor cyclists to multiply their repair d replacement bills by four, if multiplying them by o (*i.e.*, plumping for the flat twin) will do almost as ll. I think this factor may count for quite a lot. is not true that a four-cylinder gives us twice as uch trouble as a twin, and four times as much uble as a single, but it is true that in some respects is emphatically more expensive to maintain.

Another Generalisation.

THE other day I had to guard myself from a charge of lumping all D.R.'s and all M.T. men together. I now wish to challenge the many atements which dump all munitioners in the same sket. A common method of payment in munition ctories is a combination of piece and time rates. A nd performs one operation on a shell. A time is ed for that operation, say five minutes. He is paid much an hour, and his time is reckoned by the mber of shells on which he performs this operation. he gets through twelve shells he is paid for one hour, twenty-four shells two hours, and so on. The high wages now current are very often based on the fact that a very liberal time is allotted for each operation, partly because individuals vary so much in their speed. A quick worker possibly machines three shells in the five minutes allowed for one shell, and so gets three hours' pay for each hour's work. Individuals and factories vary enormously in these respects. Of course, the time allowed for stereotyped operations on stereotyped munitions, such as eighteen-pounder shells, is now pretty well standardised, but there are still a lot of odd jobs going through some of the smaller factories and some of the experimental works, and here the contrasts between patriotism on the one hand and laziness or covetousness on the other are extraordinary.

Some Examples.

FOR instance, there are factories where the machine hands, in co-operation with the charge-hands and the foremen, have fixed the time allowed for each operation at the absolute minimum, and nevertheless work like demons. In such a shop we get a maximum output at a minimum cost. In another shop we find an absurd period allowed—perhaps forty minutes for a fifteen-minute job, coupled, however, with a fast rate of working and no dawdling. Here we get a good output at very high cost, each hand being paid double time and over. In a third shop we find fifty minutes scheduled for a ten-minute job, and a conspiracy to make things very uncomfortable for anybody who "cuts it up," *i.e.*, earns more than "double time." So you cannot estimate the patriotism of a munitioner at sight. He may be wrecking his health by working long shifts, with hardly any holidays, at high pressure, and for less than half the pay which he could secure if he and his shopmates were lazy wanglers. Or he may be a born-tired grafter with no conception of patriotism. Or he may come betwixt the two. Human nature, in the army and out of it, runs in streaks.

Overhead Valves.

IT is now possible to construct an overhead valve which can be guaranteed not to break: nor are such valves either fat or heavy. The other day I saw a pilot preparing for a tolerably dangerous flight with a big engine equipped with o.h.v. which looked quite absurdly fragile, and no provision was made for preventing them going through the piston if a stem snapped. It will be interesting to see whether this valve position is adopted on motor cycle engines in the near future. On the one hand, overhead valves offer us an increased efficiency; on the other, they will be less accessible than the side pattern, and do not lend themselves so conveniently to tank design.

THE BRITISH MAGNETO.

A SURVEY OF THE WAR-TIME WORK OF A NEW INDUSTRY.

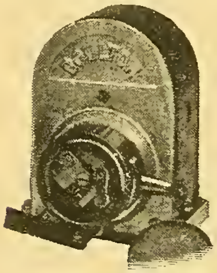
Thomson-Bennett magnetos for large singles, flat twins, and V type engines.

Types of M-L magnetos for lightweights, 3½ h.p. singles, and flat twins.

IT is safe to say that nine hundred and ninety-nine out of every thousand motor cycles are fitted with magnetos, but it is extremely doubtful whether one rider in every thousand has the same knowledge of the ignition apparatus as he has of the rest of the machine.

The majority of present-day riders were not motor cyclists before the high-tension magneto changed the question of ignition from one of great uncertainty to one of almost absolute certainty. To many the magneto is there—sometimes in a most exposed position—as something that does its work with such unfailing regularity that it passes from the ken of mechanics in the mind of its owner. It has no valves to grind, no jet to be opened out or hammered up, no cylinder to be decarbonised, and no tappets with which to tamper. It is just a thing which is understood to go round and to make a spark at the moment it is required to ignite the charge in the cylinder. Yet before its advent the ignition was the most troublesome part of the motor cycle. To-day it is the most reliable. To the efficiency of the high-tension magneto is largely due the enormous developments that have taken place in the application of the internal combustion engine to industrial, pleasure, and war purposes.

The P.M. magneto for single-cylinder engines.

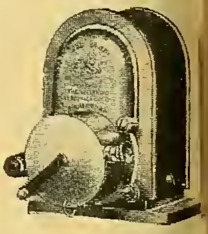


The Boulton magneto for single-cylinder engines.

Since the magneto is of such importance in the world of automobile engineering, more should be known by the individual concerning its construction, the principles upon which it works, and the firms who came to the rescue of a stranded nation when war broke out. Because a thing rarely requires attention it does not deserve less interest than the parts of a machine which periodically call for adjustment. For several years before the war this journal urged that more magnetos should be made in this country.

The necessity for this was made manifest when w broke out. It was poor consolation for us to be ab to say, "We told you so." It is far greater pleasu for us to note the magnitude of the British magnet industry now so firmly established. This new industr has filled the gap which threatened to handicap o forces in the field. It has done more. The Britis magneto of to-day is a far superior instrument to th pre-war product from Stuttgart.

One must remember that in 1914 the ou put of British-made magnetos was abou 100 per week. This means that a Britis magneto industry did not exist, for one two small firms could not be regarded eve as the nucleus of an industry. A new i dustry had to be created, and the deman upon it was immediate. It was necessa to produce magnetos *at once*. Several firm stepped into the breach and magnetos wer produced, and, in justice to them, w should realise that had they been given time, the products would have been better than they were. Th result was only to be expected. The earliest British magnetos did not give the same satisfaction internal combustion engineers had obtained from foreign machines that had taken twenty years to develop.



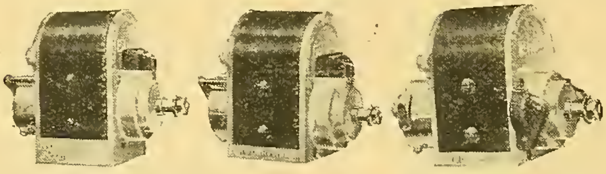
The Lion magneto, a type for single-cylinders.

Early Efforts.

Without proper tools, without suitable material, without very complete knowledge of the problems no one had troubled to overcome before th war, the infant industry had endeavoured to "delive the goods," produced in workshops instead of labora tories. At the best an imitation, a substitute.

These were the magnetos upon which are based th deprecation of those who still regard Germany as th home of the magneto.

Since the manufacture of these machines the Britis magneto has undergone a great change. It is no

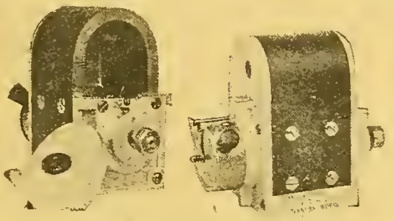


E.I C. magnetos for large single, two-stroke, and twin engines.

A group of B.L.I.C. magnetos for varying types of machine.

T British Magneto.—

oratory produced, a scientific instrument rather tn an engineer's machine. Merely to copy is to do ny things without knowing the true reasons therefor. hose reasons no longer are secrets and undefined ories. Ceaseless work in laboratory, in workshop, foundry, in organisation, has relegated the "best" yesterday to the limbo of forgtten things.



The B.T.H., a type of magneto for single-cylinder engines.

At first the importance of the estion of obtaining the special grade steel for the magnets was not ficiently appreciated. It was diffilt to obtain when its importance s realised, but the matter was ercome by the steel makers of effield, with the result that, from is point of view, the British magto is superior to the German article.

There were other problems, one by one overcome, til to-day no one can say that the home of the magto is in an enemy country.

The Result.

Up to the present time the British magneto industry, ung in years but now old in experience and knowdge, has supplied hundreds of thousands of magtos for war purposes, and as the magneto is the real art of an engine, the fact that our army aeroplanes, nks, lorries, cars, cycles, and naval motor boats and rships are equipped with the home-made article, is fficient proof that England has made good in a field quiring more than the average scientific and elecical knowledge. The eory of Bosch infalliility has been exploded.

A group of C.A.V. magnetos designed for varying types of motor cycle.

The capital now inested in the British mageto industry is approxiately one million pounds, nd it gives employment o 5,000 people, not inluding those engaged in he subsidiary trades.

Apart from the magnetos made for aeroplanes or ars and marine purposes, there are over twenty models tandardised for motor cycles. These include four akes of magneto for single-cylinder lightweights, hree for small flat twins, one for small V twins, five or medium-powered singles, two for large flat twins, two for large V twins, and one for small four-cylinder engines.

The makers of the above mentioned instruments are scattered all over the country, and are as follow: British L. M. Ericsson Mfg. Co., Ltd.; British Thomson-Houston Co., Ltd.; British Westinghouse Elec. and Mfg. Co., Ltd.; E.I.C. Magnetos, Ltd.; M-L Magneto Syndicate, Ltd.; R. B. North and Sons, Ltd.; Thomson-Bennett Magnetos, Ltd.; and C. A. Vandervell and Co., Ltd.

In addition to the above firms, who all belong to the British Ignition Apparatus Association, a body formed for closer co-operation of the industry, there are several other makers deserving of mention. These include: The British Lighting and Ignition Co.; Fellows Magneto Co., Ltd.; Messrs. Boulton; the Britannic Electrical Co., Ltd.; the Stentaphone Co.; and the Runbaken Magneto Co.

While "design" probably is the most important item in the production of a magneto, "method" undoubtedly is also very important, as proved by the fact that some of the earliest British copies of the foreign product were not quite equal to the originals, although made exactly the same as some of the foreign machines and of the same dimensions.

Advantages of Co-operation.

There is no doubt now that the British magneto industry can produce sufficient magnetos for the motor cycles which will be built in this country after the cessation of hostilities, nor that their quality will be below the high standard of perfection the trade and the rider demand. Experience has shown that to be successful a magneto must be efficient in design, extremely accurate as regards workmanship, and constructed throughout of special material. The British firms engaged in producing magnetos fully appreciate these facts, and the post-war magneto will be neither makeshift nor imitation, but the outcome of extensive experimental and research work of the magneto industry as a whole, for war has shown that the principle of co-operative action on the part of makers—exchange of ideas and discoveries among the best electrical brains in the country—has far greater value than for each individual to plough his lonely furrow.

THE GOVERNMENT AND BRITISH MAGNETOS.

IN the recent report of Lord Balfour of Burleigh's Committee, the suggestion was put forward that for three years after the war the Government should stipulate in all contracts for British magnetos.

The licence proviso would seem to be due to the objectors of the War Office, who hold that the Government must not be deterred from buying "the most efficient ignition apparatus from whatever source." There is not the slightest question that the most efficient magnetos in the world to-day are British-made. One frequently hears the unthinking ruminating on the possibility of Germany having some super-production for after the war. A moment's thought should convince anyone that Germany's finest and most recent designs would find their way on to their fighting aeroplanes. British manufacturers are soon acquainted with any new enemy device which may be worth investigation, and, such being the case, the suggestion that Government Departments should for three years stipulate in their contracts British-made magnetos seems the very least they could do to stimulate and keep buoyant this healthy and young industry in the face of the strenuous efforts Germany will be making to regain her supremacy in the magneto world.

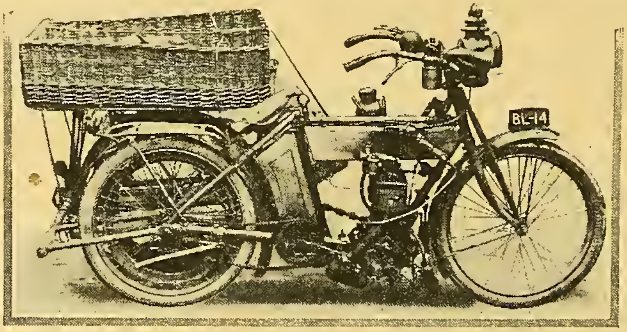
THE FLEXIBLE SIDECAR IN ENGLAND.

An Ancient Fourteen-year-old Rex fitted with a Sidecarrier designed Twelve Years ago and still "going strong."

IN the early part of this year there appeared in *The Motor Cycle* an article on the development of passenger motor cycles, in which it was stated that the flexible sidecar no longer flourished in this country. The subject was taken up by an American correspondent, and in the issue of March 28th a further article was published describing a flexible sidecar which hailed from the U.S.A. Recently we received a letter from a well-known pre-war Swift rider, F. J. Watson, who is at present in the R.A.F., suggesting that we should call upon a friend of his, Mr. E. W. Gascoyne, of 15, South Row, Westbourne Park, London, W.2, who has been using a vehicle of this type for many years.

Mr. Gascoyne is engaged in the laundry trade, which, as most of our readers are aware, entails the use of a certain amount of machinery, and having a liking for things mechanical, he set himself many years ago to build a flexible attachment to fit his 1904 Rex motor bicycle. This he has improved until it has reached a really practical stage, and he also added many useful fittings of his own to the motor cycle that has served him so well.

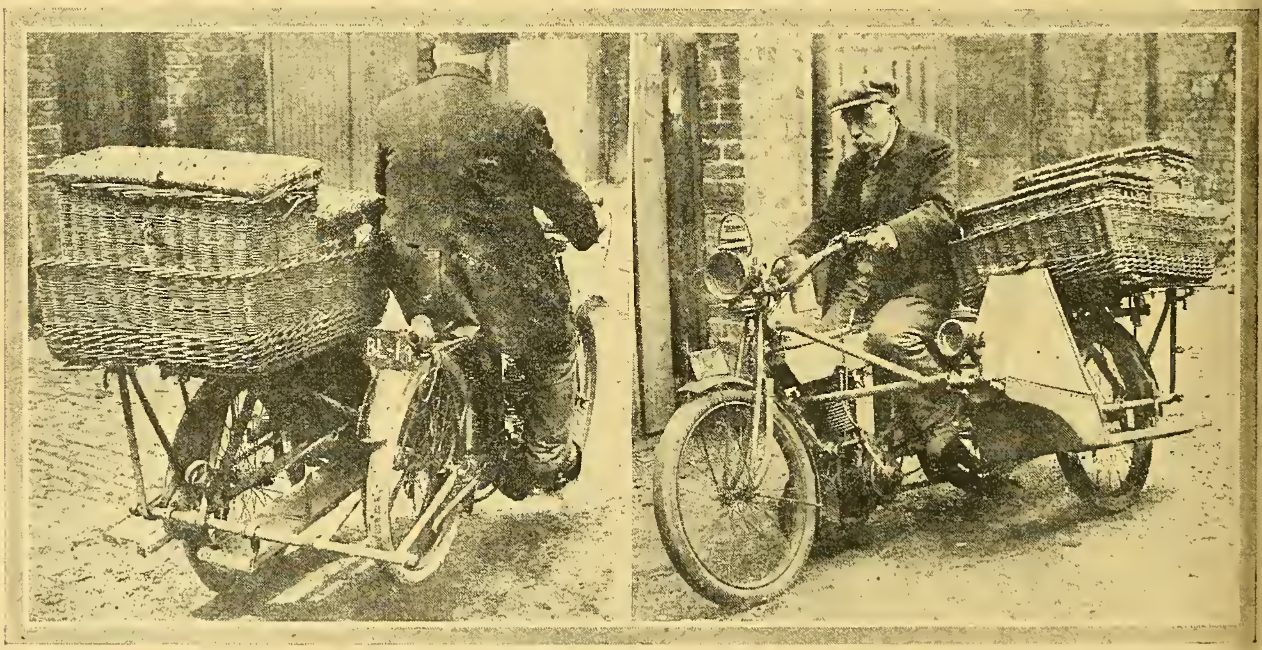
Originally the machine was fitted with a surface carburetter and the Rex Company's beehive silencer. Both these were abolished, and the engine is now fitted with a spray carburetter, and the beehive silencer is blocked up, a new outlet having been made and an ordinary exhaust pipe and silencer fitted. The frame has been considerably lowered, and the head has been strengthened by an additional tube and lugs, while the saddle has been placed in a reasonably low position. Fitted with magneto ignition and a two-speed gear, the brave old machine is now able to take its rider and a load of laundry baskets anywhere.



The modernised 1904 3 h.p. Rex, fitted with a flexible sidecarrier. A new silencer, magneto ignition, and a modern carburetter replace the old fitments.

Originally the sidecarrier was fitted with pedalling gear, a saddle and extra handle-bars, so that before the improvements were made to the motor bicycle—and it had not so much power as it has now—the passenger could assist the driver by pedalling to start and up hills. Mr. Watson writes: "I remember many a ride on the machine when I was a member of the West London Cycling Club, and was paced by the combination on such events as the London-Brighton run."

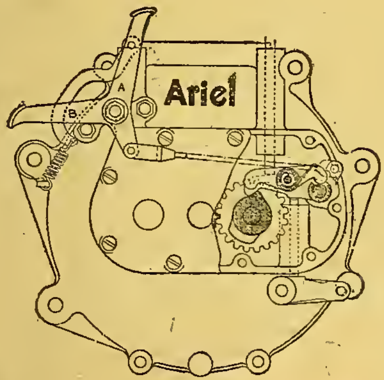
Later on the pedalling gear, saddle, and handle-bars were removed, a front wind protector was erected, a comfortable seat took the place of the saddle, and footboards were substituted for the pedalling gear.



(Left) Taking a big boulder. Note that both motor cycle and attachment remain vertical. (Right) Mr. Gascoyne negotiating a corner

EASY STARTING
OF THE
ARIEL MOTOR CYCLE
GUARANTEED

The easy starting of the Ariel is specially mentioned in nearly every letter we receive from owners. The following are a few extracts selected at random.



The Ariel (Patent) Decompressor.

A simple mechanical device—absolutely positive in action—nothing to get out of order. To bring the decompressor into operation the front lever (A) is placed in the forward position, and the rear lever (B) pressed down to bring the engine under full compression.

"Even on to-day's so-called petrol, mine starts at first kick."—W. D. W., Redbourne.

"The other night the bike was left out from 12 a.m. till 8 a.m. in a perfect rain storm. When I got to her in the morning she started up with the first kick."—
Dr. G. H., Shetland

"It is easy starting and most powerful on hills."—B. S. W., Stowmarket.

"I find the easy starting a great comfort."
—Dr. D. M. H., Bolton.

"The easy starting decompressor is a revelation."—A. B., Ulverston.

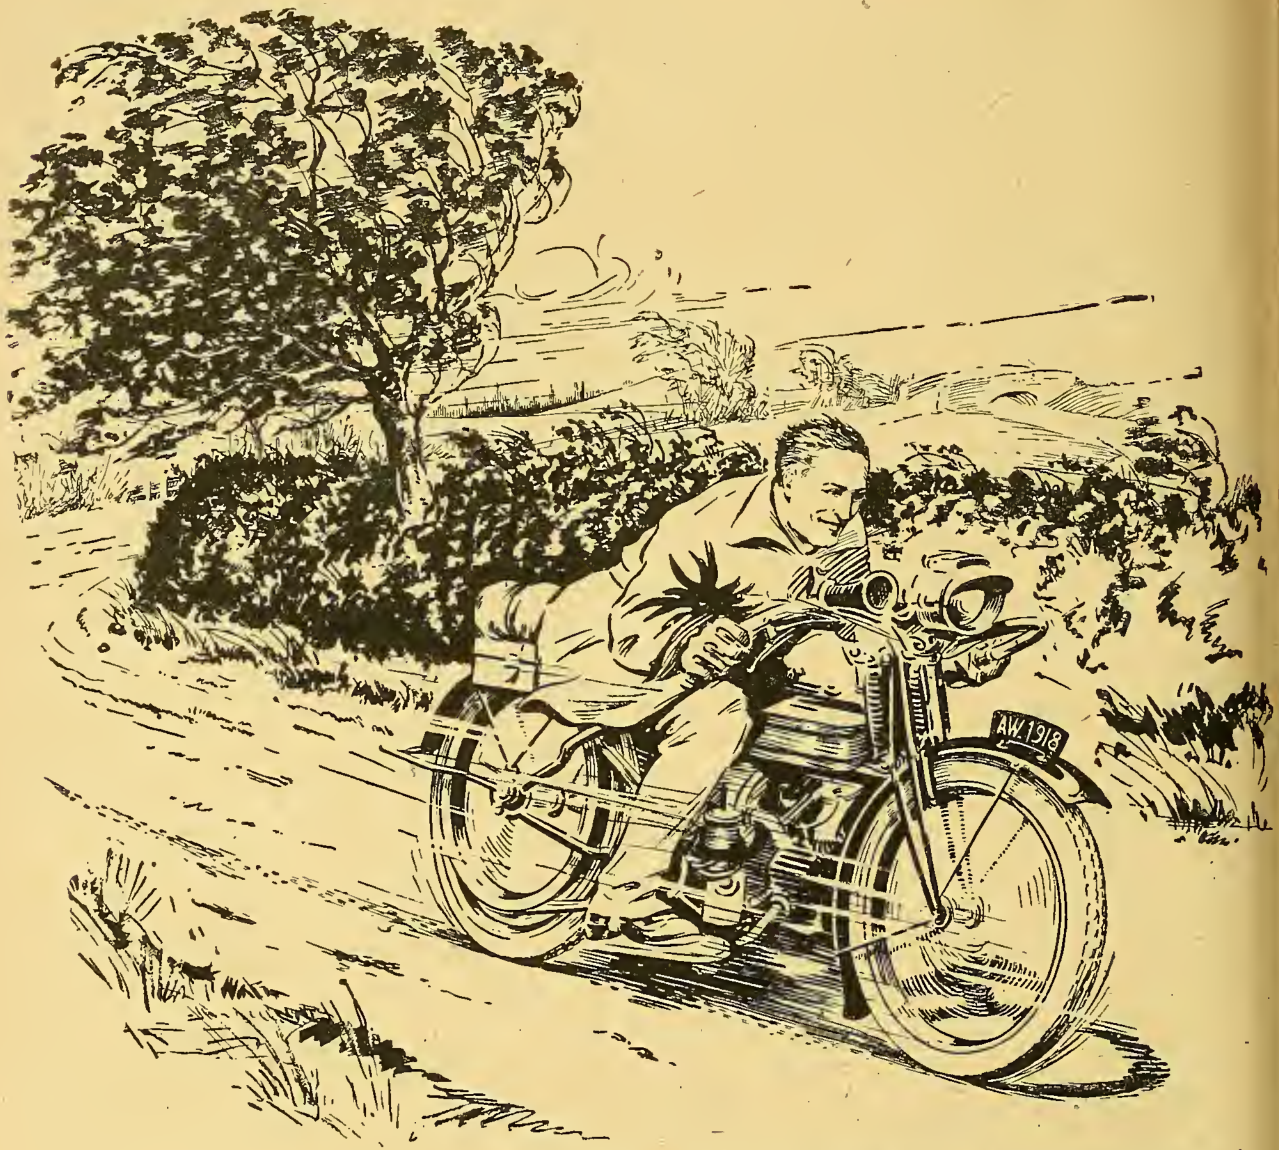
ARIEL WORKS, Ltd., 3, Bournbrook, BIRMINGHAM.

ARIEL



LET me ride with the wind on my forehead,
The beat of the air through my hair!
Let me face the rush of its passing—
The open, sweet, God-given air.

Let me face the wind in the evening,
Let its coolness revive my soul;
Let me pass from the glare of the pavement
To places where God makes men whole.

Let me feel the wind on my temples
When I answer the Last Great Call;
Let my spirit go out in a windstorm,
Clean, pure, on my last ride of all.

DUNLOP
RUBBER CO., LTD.,

he lexible Sidecar in England.—

ne rear view of the machine shows that the comition can take quite a large size bump without nt fering with the level of either sidecar attachment r icycle, both remaining vertical, and another photo-gr h illustrates that when turning a corner both ions bank over just as in the case of a solo mount. t the present time a tray is fitted to the attachment n lace of a seat, so that Mr. Gascoyne's laundry ets can be conveniently carried, and the machine s ow used solely for this purpose.

The Method of Attachment.

he rear attachment to the motor bicycle is made ugh forks swivelling on the back stand bolts, while ear bar is threaded on to a liner tube which runs right through; the front attachment comprises a movable joint made by placing two ball races together secured by double lock nuts. The cross tube from the saddle bolt to the frame, which is usual in sidecar construction, is not employed, but two tension springs take its place, and serve to keep the vehicle upright when stationary.

Negotiating Sharp Corners.

The photographs show clearly every aspect of this interesting machine, while one demonstrates the combination being ridden round a sharp corner by its gallant owner, who is sixty-two years of age. The Rex motor bicycle is fourteen years old, while the flexible sidecarrier depicted is no less than twelve years old, and both are good for many years of service.

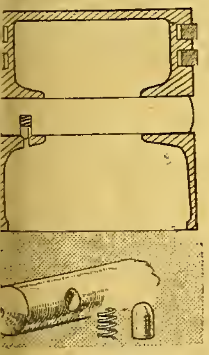
FIXING THE GUDGEON PIN.

Some Remarks on a Motor Cyclist's Bugbear.

I' would be a real boon to motor cyclists if some degree of standardisation were arrived at in the fixing of gudgeon pins. It should be possible in ry design to remove the piston from the connecting as easily as one removes a sparking plug, yet how ny engines have been scrapped or very seriously ured owing to the inaccessible fixings now in use— v many knuckles have been barked in a perspiring l irritable attempt to remove some wretched little ter from the inaccessible and invisible interior of ord the piston? In one notable example of sent-day design a special tool is necessary to get at locking screw of the gudgeon pin. To secure the ew without the use of this special implement is a tter of uncertainty, and in one depot in France, ere a number of these engines are in use, several akages have occurred owing to the locking pin rking loose and falling into the crank case—the ecial tool not being obtainable. Now, when an ificer has occasion to remove a piston he shortens gudgeon pin somewhat before replacing it, and es a thick copper washer at each end, the use of the ccessible locking screw being avoided.

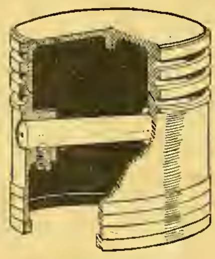
Other Systems.

We have certainly suffered some inflictions with ard to gudgeon pin fixings. First, there is the tapered gudgeon pin, requiring a tap with a hammer to fix it. This system is preferable as regards accessibility to the internal fixing screw, but one seldom knows which way to tap it, and cracked pistons often result from too liberal a use of the hammer. Moreover, the arrangement is not good, for the taper pin is apt to cause the piston to warp —a thing it is ever ready to do without special encouragement —and in careless hands the connecting rod is apt to be strained while removing or replacing the pin.



A gudgeon pin fixing nce adopted by the nakers of a well-known ingle-cylinder engine.

The gudgeon pin, then, should be a sliding fit in the piston, hence the adoption of the various internal locking gadgets. The makers of a well-known single once employed a small internal spring lock, as shown in the sketch—an arrangement which, I sincerely hope, this otherwise excellent firm has since abandoned. The gudgeon pin was drilled to carry the spring and the small shell lock, which, when it arrived opposite the hole drilled to receive it in the piston boss, sprang into position, thus locking the gudgeon securely in place. To remove it a bent spoke and endless patience were required, and very often great difficulty was experienced in inducing it to register. This system, however, was absolutely safe, and excellent in many other respects, its one fault being its inaccessibility. Other systems are equally inaccessible, and in addition unsafe, and the question naturally arises—why employ such systems when, by an absolutely obvious means, perfect accessibility and safety can be acquired? Manufacturers are apt to forget that the ordinary user has to work on his engine while it is in the frame—that he has not the whole thing open before him on a bench with an assortment of special tools for each particular job—and in consequence should study these small but important details.



A gudgeon pin screw designed to be secured by a split pin.

The Piston Ring System.

It will probably go undisputed that the piston ring method of fixing the gudgeon pin is the best. There are other excellent methods, but none quite so obvious at first glance. The ring need not function as more than merely a locking for the pin, so that it might be more easily removed than the rings at the top of the piston designed to hold compression. The locking ring cannot very well assist in holding compression, and if a spring fit inside the cylinder it would merely tend to increase friction. It need, indeed, be nothing more than a spring clip. CHINOOK.

Deserted Roads.

During a cycle ride of over eighty miles at the week-end on Midland roads, one of our staff saw only three cars and not a single motor cycle.

Price of Petrol.

On May 1st the wholesale price of petrol was raised 2½d. per gallon. This advance was considered necessary in order to cover the increased landing cost of petroleum products in the United Kingdom.

A Correction.

Last week, in a paragraph relating to "Industrial Reorganisation," we referred to Messrs. W. A. Bates as the makers of John Bull tyres, whereas these tyres are manufactured by the Leicester Rubber Company.

Stolen Motor Cycle.

Lt. C. A. S. Thornton, M.G.C., Grantham, writes to say that his motor cycle was stolen on May 9th. The machine was a 1915 three-speed B.S.A., T.T. handle-bars, speedometer, horn, lamp, generator, chain-cum-belt drive, the registration number being FC 2227.

D.R.'s and the Liberty Engine.

It has been rather amusing to hear the opinions passed on the new "Liberty" motor cycle by despatch riders who happen to be W.D. Douglas enthusiasts. They do not depreciate the machine in the slightest, but they are emphatic in their assertion that *they* would not like to be confined to a big twin for all classes of work.

Appreciation of a Gallant Airman.

We note with pleasure that His Majesty the King has shown his interest in the commemoration of the work of the late Capt. Albert Ball, V.C., of Nottingham, by accepting a copy of the volume recording the salient features of Capt. Ball's achievements. One of the authors of the work has received the following in a letter from the King's secretary: "I am to assure you of His Majesty's appreciation of possessing this interesting record of the life of a gallant officer of such renown as Capt. Ball."

Special Features.

BRITISH MAGNETOS.
A VARIABLE CHANGE SPEED
A FLEXIBLE SIDECAR.

Shaft Drive.

Judging from the correspon columns of American motor journals, the interest in shaft dri steadily increasing in that country.

"Osten-d-tatiously Vindictive."

We have received a postcard from W. Starley, whose name is well-k to many of our readers as a p inventor of motor cycle improvem which shows that he has developed a patriotic punster. He says: "Ho to the *Vindictive.* Though lost to s she is Osten-d-tatiously Vindictive s

disinterested action in volunteering
assistance for the Allied cause and
Y.M.C.A. in particular.

acuum.

e are asked to explain what causes
"suction" on a piston when it is
ed down a cylinder and creates a
um. Our puzzled correspondent
ts out that in a perfectly sealed
el the movement of the piston only
an inch would create a vacuum which
othing, and wants to know whether
vacuum is "stretched" when the
on is carried, say, half a dozen inches.
answer lies in the fact that it is not
vacuum that causes suction, but the
sure of the atmosphere (approximately
b. per square inch) on the underside
he piston tending to press the piston
. In other words, there is a pressure
5 lb. per square inch on one side of
piston and nothing on the other.

New Distinguishing Mark.

To the already numerous registration letters of cars and motor cycles for the London district LU has been added.

Two-stroke Lightweights on War Service.

It may not be generally known that a large number of Triumph two-stroke lightweights are in use by His Majesty's Services Overseas.

In New Zealand.

According to Mr. J. B. Clarkson, the well-known motor dealer of Wellington, N.Z., the motor cycle business in New Zealand has improved very much during the past twelve months.

Fords and Motor Cycles in the Colonies.

In New Zealand an American 7-9 h.p. motor cycle costs approximately £100, and a Ford car is nearly double the price. A British single-cylinder of well-known make is sold for nearly £100. In Australia the disparity between the car and the motor cycle is even greater, although the prices of the motor cycles are higher than in New Zealand.

"'Tis an Ill Wind——"

"'Tis an ill wind that blows no one any good," a motor cycle manufacturer said to us the other day. "Before the war we were pestered to death by snippet hunters from the motor papers. Now—well, we are resting." Such are the thanks the motor cycling journalist receives who in normal times hunts for news to interest the readers of *The Motor Cycle.*

Rough Rider Grips.

It is a matter for surprise that those American "rough-rider" grips have not caught on more in this country, especially in view of the state of the war-time roads. A springy core projects beyond the metal of the handle-bar, and its flex is a great saving to the wrists, to say nothing of the convenience of the knobbed end, that adds to the security of the grip. A lightweight is greatly improved by these fitments, as we can certify after 3,000 very bumpy miles with them. Occasionally it is necessary to bend the handle-bars upwards and outward slightly (if they are T.T. pattern), but this can be done cold, and is often a great improvement.

What's in a Name?

American motor cyclists appear to enjoy the distinction of being a race apart if their names stand for anything. "Bud," "Tad," "Ed," "Rube," "Art," "Jake," and "Van" are only a few of the many peculiar curtailed names they adopt.

A Motordrome?

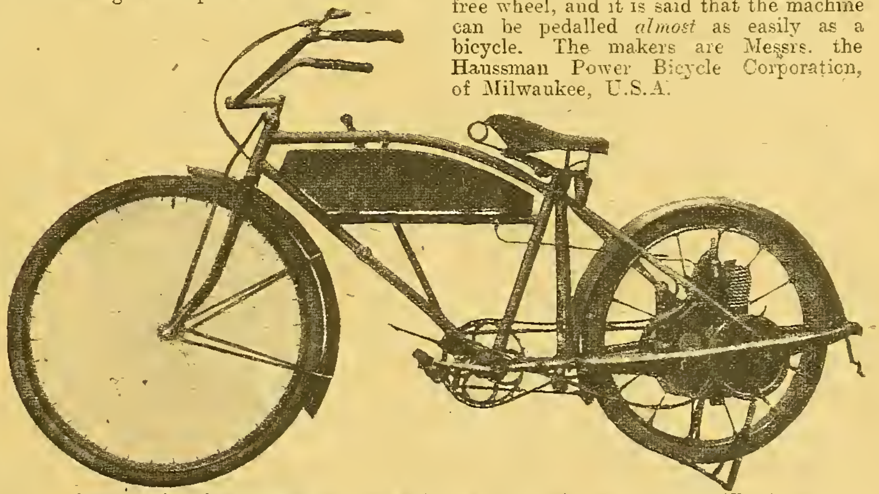
A few years ago a project was afoot to build a motordrome in the Midlands. If track racing is to become popular in this country such a track as was suggested is very necessary. Even the old cycle tracks are disappearing one by one, and while these were not suitable for very high speeds, a certain amount of lightweight motor racing was always regarded as a "draw" by cycle sports promoters. Brooklands is too far away from the Midlands to attract the sporting public, who would attend a track nearer home in thousands.

An Early Morning "Blind."

A motor cyclist in the Midlands, who finds himself with petrol but no permit to use it, recently rose with the dawn and enjoyed a thirty-mile "blind" along the deserted roads. It is stated that he was prepared to pay for infringing the law after his "joy ride," but it would have gone against the grain to be summoned for pottering at normal speeds. No doubt the spin benefited the rider; but it must not be forgotten that the police never sleep, and the early morning spin may result in a prosecution just as easily as one undertaken in the middle of the day.

A Weird-looking Lightweight.

On this page we illustrate America's latest effort to produce a lightweight motor cycle, and, to the English eye, the result is a hybrid. It is known as the Haussman, weighs 110 lb., and consists of a Smith engine built into a 24in. rear wheel with ¼in. steel spokes. The spokes are "off-centred" so that the weight of the power unit is carried in the centre of the wheel. It will be noted that the frame is of peculiar construction; but, to our eye, does not justify the American description as following "graceful, motor cycle-type lines." A free engine clutch, hand-operated, provides an absolutely free wheel, and it is said that the machine can be pedalled *almost* as easily as a bicycle. The makers are Messrs. the Haussman Power Bicycle Corporation, of Milwaukee, U.S.A.



A recent American production described as a "graceful" motor cycle. The frame design speaks for itself.

MILITARY NOTES.

Discharged Men and their Pensions. Experiences with Commissariat in East Africa.

AN UNUSUAL CAUSE OF DELAY.

THE Postmaster-General states that mails from soldiers in Palestine have been delayed by a landslide.

DISCHARGED MEN'S SAFEGUARD.

THE Minister of Pensions states that discharged men need have no fear that because they undertake regular work, and earn the highest possible wages, their pensions will be reduced. Instructions have been issued to Medical Boards definitely forbidding the questioning of men regarding their earnings.

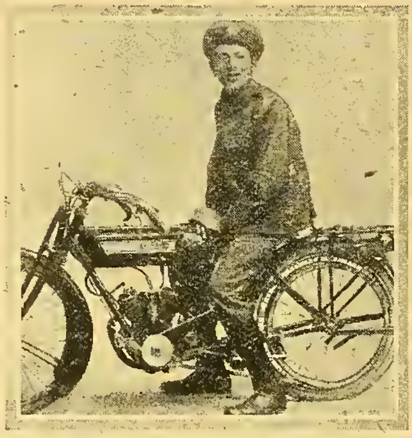
THE GAS BAGS IN ENGLAND.

CPL. KESSELL writes us from Mesopotamia, and sends us a photograph which was taken whilst the Cossacks were in that country. He says: "We who have been out in this part of the world so long are greatly amused with the new additions to motor cycles in England—*i.e.*, gas bags. I dare not think what would be the result had we to use such cumbersome devices on active service in this country. You will notice that our mounts are 1916 Triumphs, and both Cpl. Johnston (Winchester) and Cpl. Kessell (Whitehaven) are confident that they are the only machines that would stand up to the rough work amongst the hills, with which this particular division has to contend."

SEC.-LT. J. H. POUNTNEY.

SEC.-LT. J. H. POUNTNEY, A.S.C., M.T., will be remembered by our readers as one of the foremost Rover exponents in pre-war days. At the outbreak of war, he was one of the first group of motor cyclists to be enlisted by the Editor of *The Motor Cycle* for the No. 5 Battery of the Motor Machine Gun Service—familiarly known as the Coventry Battery—and was quickly promoted sergeant. After three years' service abroad he has been granted a commission in the A.S.C., M.T., and expects to return Overseas at an early date as workshop officer to a Supply Column.

Lt. J. H. Pountney, A.S.C., M.T.



Pte. E. C. Jennings, who, after serving in France, is now in hospital. Before the war Jennings was an enthusiastic owner of a twin Humber, upon which he is mounted.

EAST AFRICAN EXPERIENCES.

WE have received from Pte. G. W. Clark, who is with the East African Expeditionary Force, an interesting letter describing his experiences in that country.

He says: "After nearly two years' campaigning, I am amazed at what an ordinary single can accomplish if well looked after. I have been attached to the S. African D.R.'s for three months, and so had a chance to judge their performances. You will hardly be able to conceive the awful tropical conditions here, the lack of roads and bridges, and labour entailed on most of the journeys undertaken, which necessitate the carrying of rations, cooking pots, blankets, spades, petrol, tubes, etc. A two hundred mile journey is a common one, and this through bush and past an occasional nigger kraal, where, if one understands the lingo, eggs, chicken, fruit, etc., can be obtained. The eggs had to be consumed on the spot, or else an omelette in one's haversack was the result of trying to bring them to camp. I am afraid the chicken, which we often carried suspended by a string hanging down one's back, had a very rough journey.

"The machines were all B.S.A.'s, and the way they took hills and gulleys was truly marvellous. The chief troubles experienced were broken rims, spokes, and saddle parts.

"For some time I have been driving a car, which is bad enough, but was a luxury compared with motor cycling.

"I am sending these few notes to the people at home know there is campaign here. We hear and read big sums being subscribed to send co forts Overseas, also papers and ma zines being collected to send to fight men, but in nearly two years' servic have received only one such comfort, a as regards reading material we sim cannot obtain any. We have now clea the Huns out of the Germans' l colony, and hope soon to be back in d old Blighty."

HOW THE WAR MAY END.

THE opinion has been passed that t war will end in consequence of t demoralisation of Western Germa The enemy will sue for peace wh squadrons of over 200 aeroplanes bo the Rhenish towns weekly. Such happ ings may occur if the American prom of thousands of aeroplanes is kept.

BOY PILOTS.

IT is said that young and expert mo cyclists having technical knowled make the best pilots, and we wish t best of luck to Alex. Auerhaan, the s of Mr. Auerhaan, of the Triumph Cy Co., who in this direction will be w equipped for his new sphere of life a R.A.F. cadet.

TRYING CONCLUSIONS WITH FIFTEEN-POUNDER.

THE MOTOR CYCLE AVIATION SECTION

The enormous importance of the Air Service needs no emphasis; it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National Service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouragement of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

e Boy who Swung the Prop.

sixteen-year-old boy walked into the other day in quite a nonchalant ner, and stated that he had just ed up an aeroplane which had been d to land not far from his home. did not think it at all remarkable. ging a prop, however, is exceedingly erous work for anyone not accusd to aeroplanes, and this rather ng youngster is to be congratulated is nerve. The danger lies in back and the possible inability of the ator to get out of the way of the tly moving blade.

◆

The First Victims.

is not generally known that the first plane to be brought down by another t was that which the heroic Russian, t. Nesteroff, encountered on the 8th eptember, 1914. The attacker, having arms (it was not till later that men up rifles), deliberately headed his chine for the enemy craft; the two oplanes fell, locked, and both pilots e killed outright. Nesteroff was the t man to loop the loop; this he did April 27th, 1913—a few days before goud.

◆

"Tails Up."

t would be difficult to imagine, in scribing the temper of the R.A.F., a re felicitously apposite expression than ails up," apart from the fact that a tle jocular slang lends much colour to n. Salmond's famous message. "Tails " not only suggests the canine expression of happiness and self-confidence, but also connotes the attitude of the aeroane when she is "all out" behind a ll-tuned engine. A machine in which e motor is lagging and sluggish can ly dawdle along "tail down," and has surplus of power to expend on any anœuvres.

AIRMEN MOTOR CYCLISTS

IN pre-war days the late Lt. Graham Price was a well-known private owner competition rider of Bat motor cycles. He joined the R.E. as a despatch rider at the outbreak of war, and was in the retreat from Mons. In the early part of 1916 he was granted a commission in the R.F.C., and soon afterwards news came to hand of Price attacking at the same time three Fokker and two other enemy aeroplanes. The late lieutenant met his death during a fight in the air with an enemy aeroplane.

As showing Lt. Price's fine character, we have abstracted a few lines from a letter he sent to his mother, in which he said: "If I am killed, do not grieve for me, but feel proud that you have had a son to give in the country's cause."

The late Lieut. Graham Price, R.F.C., who, on one occasion, attacked five enemy aeroplanes at the same time. He was killed in an aerial fight.

A Glimpse of Air Fighting.

The following extract is a vivid page from the diary of Adj. Maxime Lenoir:

"In fighting, more than anything else, '*chi va piano, va lontano*' (he who goes slowly, goes farthest). I remember one day, on a job of protecting a reconnaisance, I ran full tilt into a cluster of Boches. We fought with the ultimate energy, but my machine gun jammed after a few shots. *Que faire?* I could not run; 'twould be to leave my comrades at the mercy of the enemy. I bluff; I simulate him who plays with his rivals. A sinister game! There am I, throwing every sort of *volte-face*, swooping like a madman to make them think I am trying to engage. Each time the same thing happened; the adversary, though superior in armament, skipped hurriedly. A real flight of sparrows, but sparrows more ugly than brave. A platonic success."

◆

Replacing Linen Fabric with Metal.

News comes from America that a prominent steel company is filling a large Government contract for sheet steel intended to replace linen fabric as a wing covering. After prolonged experimenting, it is stated that the metal can be rolled as thin as one-thousandth of an inch. When one thinks that a safety razor blade is about 12-1000in. thick, and the elusive cigarette paper exactly one-thousandth of an inch, this seems almost incredible. The difficulty of adequately tensioning the material, and its liability to rust, would also have to be reckoned with. Nevertheless, experimenting of this kind is to be welcomed, as nobody in the aviation business holds the opinion that the present rather flimsy wing and fuselage construction has come to stay. But wings of thin and resonant metal would surely make a sound like the cymbals of a circus band when the engine was running.

FLYING FACTS AND THEORIES.

CONTROL III. "The Immelmann" and Other Stunts.

By W. G. ASTON, A.F.Ae.S, A.M.I.A.E.

BY means of the loop combined with the roll many valuable stunts have been designed, and are daily performed in almost endless variety. Amongst these the "Immelmann," called after the famous Boche pilot, who, if he were not the first to cut this figure, was at least the first to introduce it in air fighting, stands out as a type of what can be done in the way of deceptive and quick turning. We will suppose that the machine is flying normally level as at A in fig. 1. The first operation is to roll the aeroplane through 90° until, looked at from the side, it is as at B. This rolling is now continued through another thirty or forty degrees, perhaps more in some cases, so that the machine is now heeled over and partially upside down. The next movement, C, takes the form of executing the second half of an ordinary loop. This brings the aeroplane right side up again, but facing the direction in which it originally started, as shown at D.

The speed throughout this manœuvre is pretty high, especially as the direction in which the controls are exercised is such that such energy as is lost by the extra resistance imposed during the roll and the looping recovery is, at least partly, regained from the partial dive which takes place. The controls are exercised as follow: For the first part, *i.e.*, the roll, the stick is brought right back and fully to one side (according to the direction in which the pilot desires to roll). The rudder bar is, at the same time, thrust well forward on the same side as the stick is lying, until the second part, the loop, is commenced, when the machine is straightened out according to circumstances.

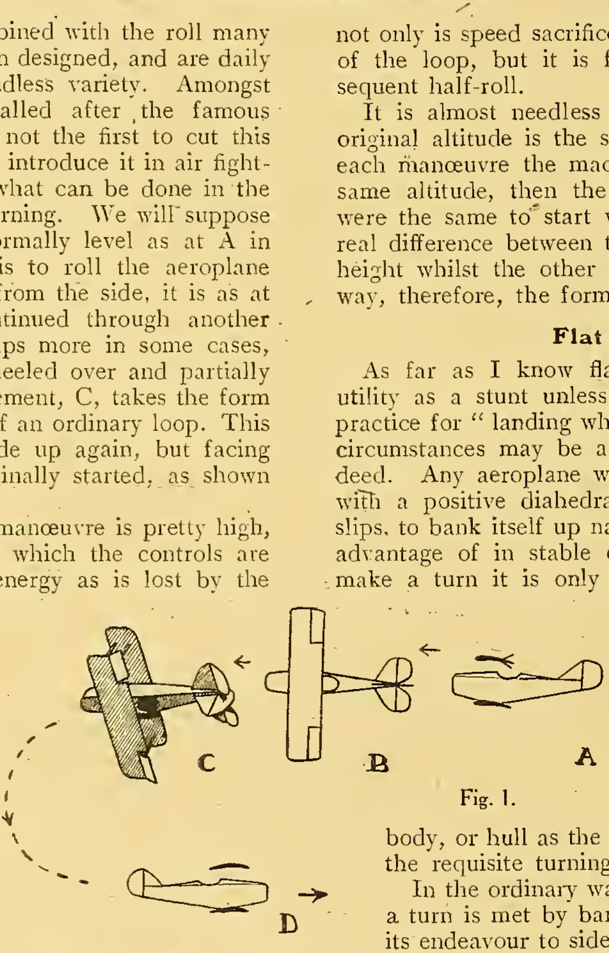

Fig. 1.

The manœuvre can be executed in the reverse direction. First of all, the upward half of a loop is carried out, which faces the machine in the opposite direction and puts it on its back. Next it is rolled over until right side up again. If performed in this manner this figure (I am ignorant of its particular nickname) tends to slow the machine considerably, inasmuch as not only is speed sacrificed heavily by the upward h of the loop, but it is further impaired by the su sequent half-roll.

It is almost needless to say, however, that if t original altitude is the same in both cases, and aft each manœuvre the machine is again brought to t same altitude, then the final speeds (assuming th were the same to start with) will be the same. Tl real difference between these figures is that one los height whilst the other gains it, and in the ordina way, therefore, the former is the faster.

Flat Turning.

As far as I know flat turning has no immedia utility as a stunt unless it be regarded as necessa practice for "landing whilst yawing," which in certai circumstances may be a very valuable manœuvre i deed. Any aeroplane which has its wings set flat with a positive diahedral angle tends, when it sid slips, to bank itself up naturally, and this fact is take advantage of in stable designs, for, in this case, t make a turn it is only necessary to use the rudde control. Now the firs effect of throwing over th rudder is not to make th machine turn, but to mak it side-slip, and the sam conditions exactly occur i a boat. It is this side-sli which promotes a resist ance on the side of th body, or hull as the case may be, and so furnishe the requisite turning couple.

In the ordinary way the tendency to side-slip o a turn is met by banking the machine over, unti its endeavour to side-slip inwards due to gravity i exactly equal to its tendency to side-slip outwards o account of centrifugal force. If no bank is put on or if the natural tendency of the aeroplane to bank itself is neutralised, or overcome, a flat turn will be made, during which it is side-slipping the whole time and so preventing the turn from being a sharp one. The rudder is used as for the ordinary turn, but th stick is thrown over in the wrong direction—that is t say, the aileron on the outer wing is set negative, *i.e.*, pointing upwards, and that on the inner wing positive, or pointing in a downward direction.

ying Facts and Theories.—

Since the manœuvre results in the air passing not raight across the planes, but diagonally, it follows iat efficiency is lost, and that the machine will tend) lose height. In order to maintain altitude and speed uring a flat turn, a considerable amount of reserve ower will have to be drawn from the engine.

Landing whilst "Yawing."

From the above it will readily be perceived that by ıfficiently operating the aps against the rudder the eroplane can be made to avel, whilst still on an ven keel, practically dead ideways, though in doing o it will inevitably lose eight very rapidly.

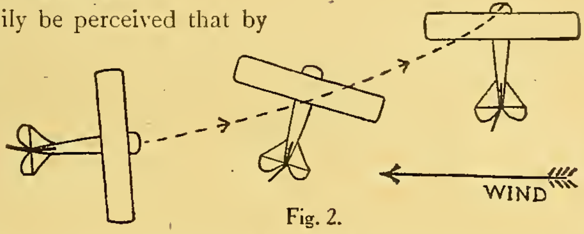

Fig. 2.

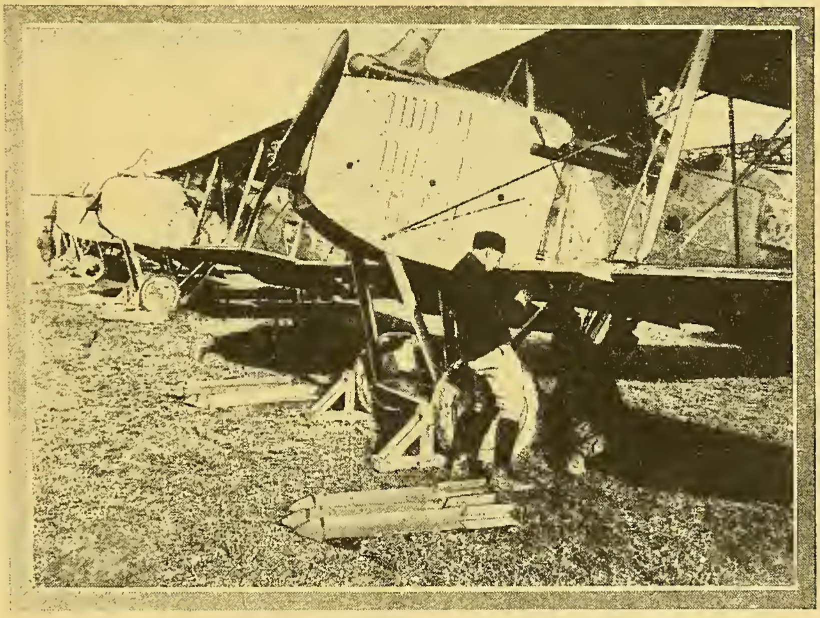
When an aeroplane is brought to ground it is obvious hat no side-to-side motion is desirable, otherwise the vheels, in resenting the skid demanded, will impose ıeavy strains on the landing gear, hence it is usual to and against the wind, or, in fact, anyhow but across t Supposing, however, that the conditions (engine ailure fairly close to the ground, for instance) are uch that the aeroplane *must* be landed across the vind, this ability to yaw (the word, is, to all intents and purposes, interchangeable with "side-slip") is very valuable, as it enables the pilot to drive his machine *into* the wind, whilst still pointing *across* it. To land, the pilot yaws his machine more and more into the wind, so reducing his yawing speed, relative to the earth, to nothing at all, whilst at the same time the forward speed of the machine is also greatly reduced. At the moment of touching ground, therefore, the aeroplane has no motion relative to the earth except a slight forward one, and landing conditions are thus perfectly complied with. The run of the machine after touching will also be very small. Fig. 2 shows the progressive stages of the manœuvre from above, the ground conditions being supposed to be such (as indeed they may easily be) that a landing either against or with the wind is out of the question.

It is almost unnecessary to add that for landings of this description the proportion of yaw applied is naturally dependent upon circumstances—that is to say, the motion of the aeroplane may be anything between dead into the wind and dead across it.

1910 IN AVIATION.

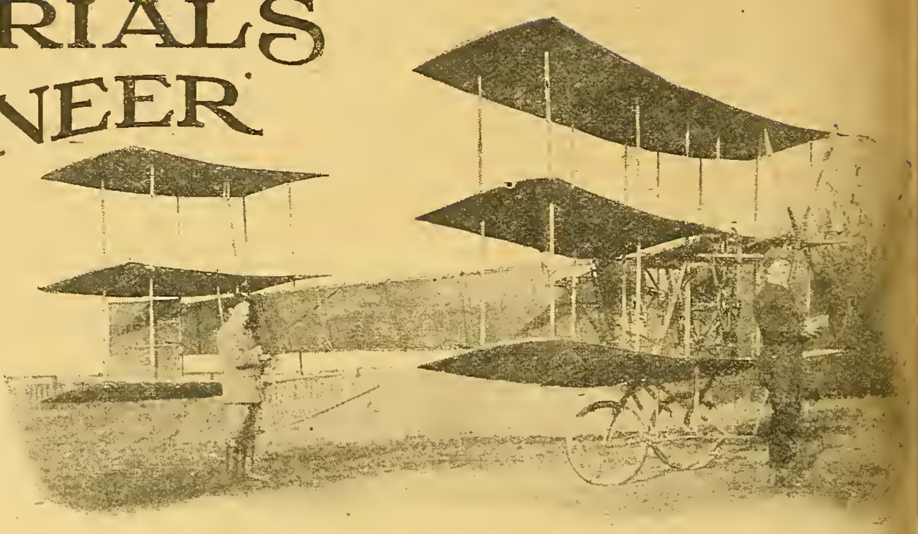
THE year 1910 was, perhaps, the most eventful in the evolution of the aeroplane. In April Paulhan flew from London to Manchester with ıne halt in 4h. ?m., and won :he *Daily Mail* £10.000 prize. In May Glen Curtiss flew from Albany to New York, 150 miles with two halts, in 2h. 54m. In June the Hon. C. S. Rolls flew from Dover to Calais and back without alighting. In July Mamet flew for 1h. 38m. 20s. with two passengers on a monoplane. In the same month L. F. Morane flew twenty kilometres at Rheims at an average speed of 66 m.p.h., and on the same day M. Olieslaegers completed 245 miles in 5h. 3m. 5s. In August, M. Chavez attained a height of 5,850 feet at Blackpool, and a few days later, at Douai, France, Bréguet carried five passengers on his biplane.



At a French aerodrome. Aviators preparing the adjustments of bombs under the wings of an aeroplane.

December was the busiest month, as between the 18th and 31st several record flights were made. At Buc, France, Henry Farman made a flight of 8h. 12m. 54s., and on the same day T. Sopwith flew from Eastchurch, Isle of Sheppey, to Beaumont in Belgium, 169 miles, and won the De Forest £4,000 prize. At Pau, France, Legagneux flew 320.6 miles in 5h. 59m. 59s. on a Blériot monoplane. At Los Angeles, U.S.A., Hoxsey attained a height of 10,400 feet. At Buc, France, Tabuteau flew 362.8 miles in 7h., and at Farnborough Colonel Cody flew for 4h. 47m., covering 189.3 miles, and won the British Empire Michelin prize. From the above it will be noted that to France, Great Britain, and U.S.A. alone is due the credit for the early development of the aeroplane. Germany achieved nothing.

THE TRIALS of a PIONEER



Flying with an 8 h.p.-engined Aeroplane.

BACK in 1907 Mr. A. V. Roe, a versatile English engineer, who had in turn tried his hand at motor, marine, and railway mechanics, became interested in the pioneer work of the Wright brothers. The cycle mechanics of Kittihawk were experimenting busily, and their example, together with the success of Otto Lilienthal, decided Roe to experiment with gliders. Later he constructed a model, driven by the usual twisted elastic strands, which won a prize offered by the *Daily Mail*.

By dint of great effort Roe managed to scrape together enough money to build an experimental biplane. Readers will remember the ridicule with which early aeronauts were covered, and not the least of the difficulties that the experimenter had to contend with was the rasping humour or utter indifference of the public. No record appears to have been kept of the performances of this first machine, but this much is ascertainable; if the machine ever did leave the ground it can have made little more than an extended hop, as there does not seem to be any record of it in the technical press of that time.

The next machine, which is the triplane illustrated, made history, for it actually got off the ground. Motor cyclists who do not happen to have heard of this craft will be interested to learn that it was equipped with a standard 8 h.p. air-cooled J.A.P. motor cycle engine. The machine itself was constructed of various odds and ends, portions of a superannuated pedal cycle playing a prominent part in its make-up. This was not the sort of power unit that one would have selected for so momentous an experiment, but, like most of the pioneers, young Roe was woefully handicapped by lack of cash, and, in the face of the scepticism referred to, it was practically impossible to secure capital for work of this kind.

Flying in the Face of Providence.

In the autumn of 1907 this little 'bus was run out on Lea Marshes, that desolate tract of land in the north of London, an abode of stray cats, tomato tins, and ash heaps. The machine indubitably flew, though its progress was erratic, to say the least of it. The authorities, enraged at this literal flying in the face of Providence, forbade further experiments here on the ground that the grass was being spoilt for grazing!

In the light of his vision, Roe persisted. Another experimental machine left the ground at Wembley Park. The pilot endeavoured to turn sharply, but fell, and the planes were rather badly damaged. This accident was ascribed to recent modifications in the steering arrangements which had been carried out. About this time the veteran Cody was meeting with some measure of well-deserved success, and in an attempt to win the thousand pounds prize offered for a flight from Liverpool to Manchester he succeeded in covering ten miles. An heroic feat in those days!

Roe's Wembley experiments came to an untimely end, as the owners of the enclosure where the flying was done insisted on the machine being lifted over the spiked railings each night and placed outside. Levitation of this kind proved even more disastrous than the regular flying, and the machine was put out of commission through rough handling.

In 1909 matters had progressed so far that a flying meeting was held at Blackpool, and Roe decided to put in his entry. The Frenchmen had secured a very considerable lead in the art by this time, and poor Roe's "grass-cutting" efforts were hailed with unholy glee by the crowd that had become *blasé* with the more showy flights of the competitors from abroad. They unkindly dubbed the Avro, which, like d'Artagnan's horse, was the colour of a buttercup, the "try-try-try-again plane." Nevertheless, in it were the elements of the very successful fighting machines which this concern has turned out since.

A Non-standard Aeroplane.

A year later another meeting was staged at Blackpool, but the train which carried Roe's two machines was wrecked, and nothing was left of them but a mass of burnt scrap! The plucky pilot telephoned his little works at Manchester to extemporise a machine out of anything that was handy. Scraps of mummified aeroplane were hurriedly sorted out, and in three days the machine was ready. Two more days elapsed in anxious waiting until the Green vertical engine which had been wired for arrived; and on the same day that it came to hand Roe flew, accomplishing two and a half circuits of the course. He had to come down because the machine was practically uncontrollable.

In 1911 Roe reverted to the biplane form again, and in 1912 he constructed a totally enclosed type of machine, engined with a 60 h.p. Green. The 1913 machines were powered with an 80 h.p. Gnôme, and since that date Roe has more than held his own in the British aviation world.

R.H.B.

THE MAXIMUM PENALTY.

How a Thoughtless Act might have ended in Years of Imprisonment.

THE leave boat landed me at —— on the day on which motoring for pleasure was forbidden; but ten days' leave to England render ne a little reckless, and it took me some two seconds decide that I would ride my old Triumph and chance it.''

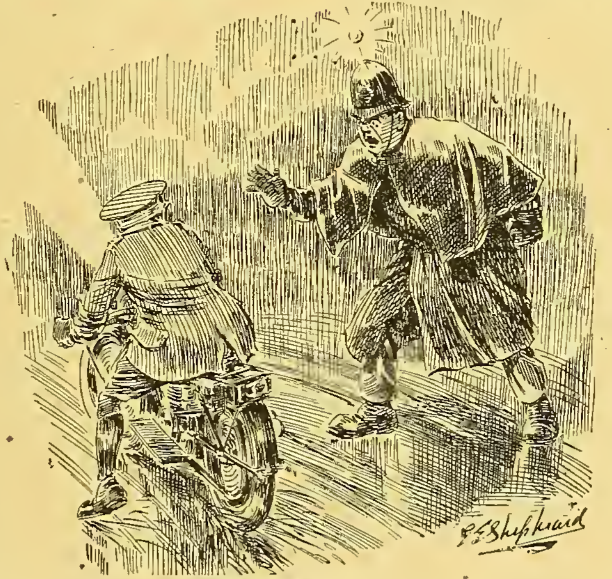
Petrol, that mystic and forbidden liquid, had lain idden in my shed for two long years—petrol, not of iat paraffinish, Government variety, but of the good ld No. 1 Shell brand. The bicycle I discovered be a dust-covered patchy affair of rust and aseline. The jet had choked itself in the velve months that had elapsed since my last eave, and the rocker arm of the magneto was tuck permanently open. But the engine would go ound, and the tyres were in fair condition. A few ninutes' attention to the magneto and carburetter, little Pears soap on an old leak in the tank, a allon of petrol, a pint of oil—and the machine was eady for the road.

My first run finished at a garage in Birmingham, vhere I left the old bicycle intil the end of the evenng. Emerging from a second-house music hall, I sought in vain for a restaurant where I could get some coffee: but cold and defeated, I decided to go nome on a tram rather than skid through the November fog on a smooth-tyred, single-geared motor bicycle. So I reached the tram terminus ten seconds after the last tram had left it.

Taxis seemed non-existent, and had they been in evidence their drivers would probably have refused to take me the distance. A five-mile walk seemed almost more disagreeable than a five-mile "mud-plug," so I went off to the garage and devoted half-an-hour to my ancient lamp. This finally responded to efforts by bursting into a flame which blew out the glass and cracked the reflector; but by this time I was too disgusted to worry, so I shoved the machine from the garage and ploughed off through the filmy darkness.

For a mile or so my journey was without incident, if one excepts a few skids in avoiding late theatregoers and others with a desire for suicide. The engine chugged along well, and the lamp, pointing, like Agnes Wickfield, sweetly skywards, gave a fair imitation of a "miniature mobile searchlight." This glare on the fog cut off my vision, and made steering rather difficult, but by leaning well over to the right and tilting my head a bit further I managed to get a restricted view.

Presently I noticed a red glimmer some twenty yards away to the right, and as I drew nearer I saw that it was a small red lamp. Suddenly it began to bob up and down, and a second later came leaping across the road towards me. Fog, we are told, may penetrate the brain; in this case, at any rate, I had a fleeting vision of a crash as I swerved violently away from the little red light. It was not until I was recovering (with much foot assistance) from my skids that I remembered the Birmingham custom. For, since the darkness of the streets, the learned councillors of Birmingham have supplied the police force with little red electric lamps, set like an apple on a hat-pin above the helmets of the traffic controllers.



"Now then! Watcher ——"

"Now then! Watcher ——" was all that I heard from the sound-box under the lamp before the Triumph had borne me out of earshot; and, being once passed and lost in a world of fog, I felt little disposed to go back and see if he wanted to borrow a match. Policemen at all times are no men to consort with, and a single-geared $3\frac{1}{2}$ h.p. is not pleasant to start on a slippery gradient.

Ten minutes after the incident I had pushed the machine into its garage, where I noticed that the tail lamp had gone out.

Next day I looked over the machine and thought carelessly of the night before. I remembered the little red lamp—and the incident made me smile. Then I thought again, and saw in it a more serious light. Supposing the "arm of the law" had shouted me to stop? Supposing, after all, he had not wanted to borrow a match to light his—er—slide lantern? What if he had imagined I was driving to the danger of the public? Policemen's imaginations were, as I knew

The Maximum Penalty.—

to my cost, of a most remarkable and elastic nature. *If* he had ordered me to stop—and in my pessimistic mood I would not give myself the benefit of the doubt —I had committed a "crime." I laughed and told myself I should be back in France. I felt the front brake, thought of the extinguished tail lamp, remembered the petrol licence—and fled into the house for a sheet of paper.

The First Step in a Career of Crime.

Hurriedly I enumerated my crimes and shivered to myself as I thought of them. I had started, twenty-four hours before, on a harmless motor cycle run of some twenty miles in length. I had finished it and had slept, as I thought, the sleep of a just and weary man. Now in the cold, clear daylight I realised my "frightfulness."

Here is the list of my misdeeds:

(1.) Driving to the danger of the public.

(2.) Disregarding the policeman's signals.

(3.) Carrying a head lamp which could be swivelled up and down.

(4.) Riding with number plates not illuminated. (Head lamp pointed at sky.)

(5.) Riding with number plates which, even if illuminated, were quite illegible.

(6.) Riding with number plates which, even if illuminated and legible, were fictitious.

(7.) Carrying too powerful a head light.

(8.) Carrying no rear light.

(9.) Driving a motor cycle fitted with a silencer cut-out.

(10.) Driving a motor cycle without an instrument (except the engine!) capable of giving "audible warning of approach."

(11.) Driving without any sort of licence to obtain petrol.

(12.) Driving for "pleasure" after prohibiting law.

(13.) Not being in possession of an Inland Revenue licence.

(14.) Carrying no licence to drive any sort of motor vehicle at all! (Old licence had expired two years ago!) And

(15.) Driving a motor cycle not fitted with two independent brakes.

Having enumerated the offences I placed them in two classes:

Class A.—Offences under the Motor Car Act. Nos. 1, 2, 4, 5, 6, 8, 9, 10, 13, 14, and 15.

Class B.—Offences under the Defence of the Realm Act. Nos. 3, 7, 11, and 12.

A Fugitive from Justice.

I now observed myself to be a criminal of the most hardened and pronounced type. Even a hurried return to the zone of hostilities could scarcely save me from fifteen different offences committed at the same moment—four of which offences came under that most stringent of all Acts, the Defence of the Realm. The Passchendaele Ridge was no health resort, but its dangers seemed slight to those of the police court and the dock. But there was one saving point: *I had not been caught.*

I returned to the shed, locked the doors, and threw away the key.

Then I felt that I was fairly safe, but I was interested in the matter, so I settled once more to my slip of paper and worked out, very roughly, the maximum penalty. (Natural modesty—and a sneaking fear—prevented me from going to the local police and discovering from them the accurate greatest fines or terms of imprisonment which could be imposed by a stern judge or magistrate.)

"Driving to the danger of the public" might be rewarded by a £50 fine or several months' imprisonment. Disregarding the policeman's signals might be taken as a terrible offence, and met by a similar punishment. The number plate offences were not so serious—except the last, which I had read in the papers once cost a cycle repairer twenty pounds. Nos. 8 and 10 were comparatively slight affairs, but in respect of a silencer cut-out I had already suffered twice. Nos. 13, 14, and 15 might between them run to about £100 fine or a year's imprisonment.

Safe at Last!

Then I turned to Class B, and as I thought of the possibilities in that direction "the sweat poured down my brow" (as the novelists would say). Carrying too powerful a head light—and a swivel one at that—was an offence which could only be connected with German spies and aeroplanes, and the penalty might be "death or some such lesser punishment as is hereinafter mentioned."

Here I fainted (almost).

The last two offences, for which I might reasonably have been prosecuted, could scarcely have cost me more than £100 or a year's prison, and they therefore seemed trivial to those which I had already committed.

The total amounted to some few thousand pounds in fines, about thirty years' hard labour, or, in atonement for all, death!

* * * * * *

A few days later I was back in London with my ten days' leave near its end. The horror of the police had gradually left me, and as I walked about Piccadilly I was filled with a vast contempt for their trivial authority. Smoking a cigarette, I crossed the street boldly and swung my cane perilously near an immovable limb of the force.

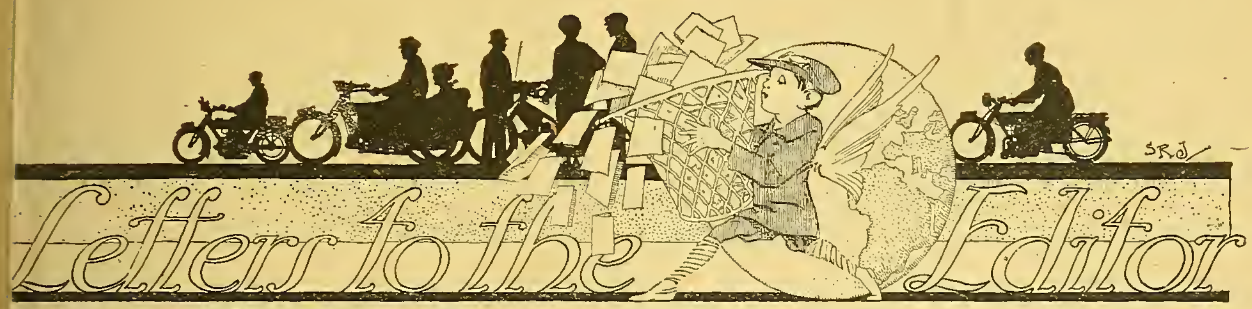
Then I ran into an A.P.M., who wanted to know (1) why my shirt and collar were nearly white, (2) why I was wearing shoes instead of boots, and (3) my name, address, and unit?

Truly are the police like the poor, for in some form or other they are ever with us!

But, thank heaven, I am now back in the Line, and can write this and think over my misdeeds in safety and peace. G.D.

OVERHEATED GUDGEON PINS.

SOME months ago we published an article dealing with the crown of the piston as the hottest spot in the average engine, and it is common knowledge that special designs of aluminium piston have been framed to conduct heat away from this very warm spot. Now the talk is of overheated gudgeon pins. The new radiation systems have proved so successful that the piston crown has degenerated into a refrigerator, but the conducted heat has dried up all the oil in the gudgeon pin bush, which promptly shows its resentment by seizing.



The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address

EAVY WORK FOR A TWO-STROKE.

Sir,—There must be many owners like myself of the 2¼ h.p. o-stroke Enfield who would like a little more information the feasibility of adding a small sidecar to the machine. There appears to be power enough, and a sidecar would aterially increase the usefulness of the machine as a run-out and carrier, and in my case would, in all probability, but rarely used to carry a passenger.

I was not aware that there was a sidecar with 24in. wheels the market.

Hoping to hear the experiences of riders and readers,

Birchington-on-Sea. BUNGALONIAN.

ACKRESTS FOR MOTOR CYCLISTS.

Sir,—I had occasion lately to undertake a ride of 200 miles, d, being doubtful about supplies, took a tin of petrol on e carrier. I placed a cushion of straw between the saddle d the tin, and was astonished to find the comfort it gave. usually feel backache for a few days after a long run, but this occasion it was entirely absent. In future I intend tie a tin, empty or full, on the carrier for the sake of mfort on long runs, though perhaps it does not look beau-ful. The problem presents itself: Would it not be possible devise a spring back on the saddle or on the carrier?

Milford, Donegal. CUSHION.

[There are several backrests already on the market.—Ed.]

YDROGEN FROM WATER.

Sir,—The subject of petrol substitution is at the present ime a very important question, and therefore a very interesting one.

It has occurred to me that if water could be decomposed n a sufficient quantity and speed to supply the engine with ydrogen a very good substitute might be thus obtained.

The decomposition of water by means of electrolysis first resents itself to the mind, but this method would be too low on account of the limited amount of current that could e generated on a cycle. Could not the hydrogen be liberated y some chemical means? Perhaps some of your readers who are chemists will give this matter some attention, if it is worth it. AN INTERESTED READER.

Newcastle-on-Tyne.

CONCRETE ROADS.

Sir,—*Re* your article on concrete roads, in the issue of 9th May, I should like to ask, "Why concrete?" The majority of London roads (those that are not wood blocked) are of Val de Travers asphalt, which seems to me to make a very smooth and lasting surface. I should like to see figures comparing these two methods—from the points of view of expense and life.

To put forward a suggestion. Would it not be possible to roll sheets of steel to the required camber, and lay them on a secure foundation?

If this could be done, I think that half the accidents arising from pure inability to pull up in the distance given (wheels skidding and so on) would be obviated, because vehicles could have a magnetic brake, which, of course, is the most powerful form of brake known.

This may probably cause you to smile, but I think that you can but agree that the idea is reasonable, and that it would lessen the number of accidents. It seems to me that the construction of the steel plates should be an easy matter.

L. W. E. HARTLEY.

GAS TRACTION.

Sir,—In your leading article in *The Motor Cycle* of May 2nd, you discuss the Gas Traction Committee's interim report, wherein the Committee gives its unanimous opinion that the substitution of coal gas in place of petrol for the propulsion of motor cars can be effectively, safely, economically, and promptly carried out.

You, however, have taken very little notice of that part of the report dealing solely with gas bags, wherein the Committee states that "the working life of a gas bag made in accordance with its specification may be considered to be, normally, about eight months; while gas bags made of inferior fabrics may leak after being in use only one month, to the extent of losing as much gas as they use."

This seems to me to condemn absolutely the gas bag as a commercial proposition, as, even when employing the best possible fabric for making the bag, the capital outlay has to be repeated at the end of eight months; while the waste of gas when using a cheaper bag is already 100% of the amount consumed in the engine before it has been in use five weeks. Such a waste of gas is unpardonable in war time, and it is quite probable that this is the reason for the sudden cessation of the issue of fresh gas permits.

I understood that this interim report was originally intended only to review the employment of gas in flexible containers, but no doubt, owing to the waste of gas reported as above, the Committee has already investigated the question of compressed gas, and its report in that respect is most satisfactory, for the Committee says in paragraph (17) Metal Cylinders, "It is desirable to encourage forthwith a limited number of experiments on a commercial scale with compressed gas in rigid metal cylinders at pressures of 1,800 lb per square inch (120 atmospheres)."

The 3 ton Wolseley lorry fitted up on the Flugel compressed system for the M.T. War Dept. was fully tested by the Senior Inspector of Army Transport and inspected at work by the Gas Traction Committee, and gave entire satisfaction; but it is evidently now desired that this high-compressed system should be taken up *on a commercial scale*, so that its marked superiority to the flexible container can be fully demonstrated.

I understand that (if necessary) a special licence will be granted for this purpose by the Board of Trade, but that gas permits already granted to users of gas in flexible containers can be used for this purpose. I shall therefore be glad to get in touch with any firm who is considering the question of using compressed gas for essential transport purposes. The cost of driving on gas is only about one-third of the cost of driving on petrol, so it is quite certain that after the war commercial firms will all use gas. One large municipal authority whose petrol motors have been converted to the compressed gas system tells me that it saves 25s. per day per vehicle by substituting gas for petrol—no small advantage.

Having felt certain for a long time that the only solution of the fuel shortage problem is the use of compressed coal gas at medium or high pressures, I, in my capacity as director of Messrs. Flugel and Co., Ltd., have made preparations in good time, so that at the moment we hold in stock for immediate delivery all the necessary material, including compressors, steel bottles, reducing valves, gas carburetters, high-pressure tubing, pressure gauges, and everything else necessary to make a start forthwith upon a commercial scale.

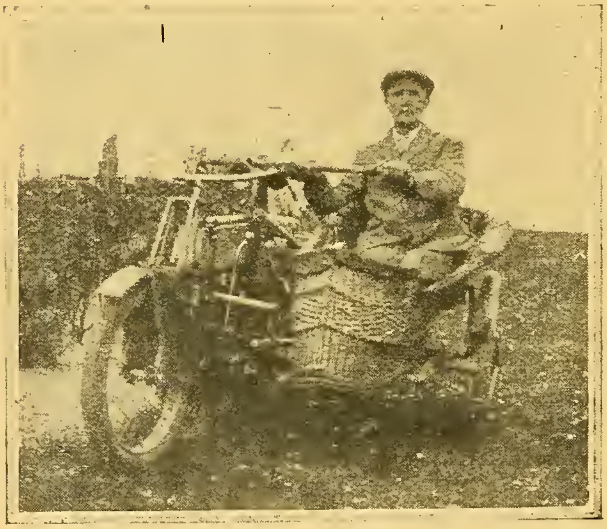
B. FLUGEL.

PETROL FOR MUNITION WORKERS.

Sir,—I, for some time, applied for petrol to go to and from a plantation, involving a distance of ten odd miles per diem. At last, in despair, I gave up, and found I could manage quite well with the pedal cycle. I have no grudge against the munition worker and his petrol, but surely a man can manage to cycle two or three miles, even if he has been standing on his feet for twelve hours. I consider digging all day just as tiring to the feet as standing. Much as I like the push bicycle, the motor bicycle is, obviously, better still; but the former involves no great strain to propel, and provides exercise as well. C. McCLELLAND.

MOTOR CYCLING FOR THE MAIMED.

Sir,—I am sending you a photograph which, I think, will be of interest to any of your readers who are maimed. For the last few years I have only been able to walk with difficulty for a few yards, and in your issue dated March 13th, 1913, you reproduced a photograph of me being driven by my wife. Since the war my wife has driven a motor 'bus for three years, and is now serving in France in the W.A.A.C.'s as a motor driver. I was compelled either to alter my machine and drive from the sidecar or else give up the pastime, which I had found of great benefit to my health as an invalid. The photographs show the result of my attempt, and will also prove me to be more of a sailor than a mechanic. Anyhow, the thing is a great success. My first long ride driving myself was from Deal to Southend, crossing the Thames by the Tilbury Ferry, and all went well both out and home. The machine is an old Chater-Lea-Jap, and has been running almost daily since 1912 without attention except from myself. The design of the whole outfit lends itself to very easy control from the sidecar. The two-speed gear, which combines a clutch, is close to my right hand, all the controls and the brake are at hand, and I start the engine by a handle attached directly to the engine-shaft. I have been riding the machine for some years now, and feel quite at home on the road.



An old Chater-Lea outfit converted to control from the sidecar.

F. R. BALCHIN, Lt. R.N.R. (retired).

THE SPRAG BRAKE.

Sir,—Judging by the issues for the last few months of your world-famous journal, this is a time of improvements both in the design and fitments of motor cycles.

I write to endorse a serious "want" in the sidecar class. I speak from personal experience, having owned several heavy outfits. The brake levers on a sidecar should be capable of being locked on as on a car.

How ridiculous it seems to have to back your outfit into a gutter when stopping on a hill. When there is no gutter one looks around for a brick—if there is a brick, how are you to get it, if it is out of reach? Sometimes it is an embankment against which you back the machine. I found the mudguards too weak for this purpose. Sometimes a kind friend left his car on a hill properly braked to come to my assistance while I got away on low gear.

I am aware you prefer constructive criticism to the destructive species, therefore I submit one or two ideas, that may be of value to manufacturers and others as a means of surmounting seemingly impossible obstacles. Material required: A brick and some cord. One end of the cord is tied to the saddle, the other end to the brick, the cord passing from the saddle over the back stand. Thus, the brick can be lowered by undoing the cord at the saddle, when the brick will reach the road just behind the back wheel, the only disadvantage of this "ingeniosity" being that it is only available when the stop is made facing up a hill.

However, the following may be a better idea (although improvement seems doubtful).

By name, "Sprag-brake," consisting of a centrally pivoted footboard, having a steel spike at each end, which can be let down either way into the road most effectively.

A simpler way than either of those stated is that "She" can have ready in the sidecar with her an ordinary domestic broom. She will soon learn under which wheel it is necessary for her to put the head (the broom's head).

TOP-HEAVY.

A BAFFLING EXPERIENCE.

Sir,—Referring to the letter from Mr. F. W. Chapman in your issue of April 18th, may I take up a little of your space in order to air my views?

1. *Plug.*—No plug is immune from breakdown, but I have never yet in my motor cycling experience handled a plug which, after giving up the ghost, cured itself without external assistance. Mr. F. W. Chapman's second plug, after reposing all night in his pocket, among the dirt and *débris* that a motor cyclist's pockets usually contain, consented to deliver a spark in the morning at the first depression of the kick starter, after refusing to do so at midnight the previous night while *in situ* in the cylinder. I therefore submit that the *plug* was not at fault.

2. *Magneto.*—Magnetos have their little aberrations, and chief of these, methinks, is a sticking rocker arm on the contact breaker. Since Mr. F. W. Chapman failed every time to obtain a spark with the plug in the cylinder, and succeeded every time when the plug was placed outside, I think that the succession of coincidences required to make his failures and successes agree with the stickings and normal workings of the rocker arm is far too remotely improbable to be given serious consideration.

Moisture in the magneto spells one of two things—either total temporary breakdown of the ignition system, or so weak a spark at the plug that its puerility may be observed, particularly at night time, when the plug is placed on the cylinder and tested in the usual manner. Since Mr. Chapman obtained a healthy shock every time he held the high-tension terminal, we may therefore exonerate the magneto from all blame.

We are thus driven to conclude that a short circuit exists between the magneto and the plug, appearing only when the plug is in position in the cylinder. My solution of the mystery is based upon the assumption that Mr. Chapman has, tied or strapped round his tank, either knee-grips or bags of some description, the underside being in close proximity to the central electrode of the plug when the latter is in position. In normal circumstances, leather is a fair insulator, but at night time, owing to dew deposit, it gradually becomes a good conductor, and may easily become the source of baffling short circuits of this nature.

Many years ago, in the Golden Age, I had a similar experience when riding an old single-cylinder Fafnir with coil ignition. I used to carry the coil on the top of the tank, secured in position with leather straps. Late one night, when miles from anywhere, the engine gave up the ghost, and it was only after much trouble that I discovered a short from the coil to the tank *viâ* one of the straps, moist with dew.

I should be pleased to know whether Mr. Chapman has a hooded terminal to his Lodge plug, or whether he is employing the ordinary metallic terminal. I should also like to know whether my assumption as to the existence of straps, etc., round his tank is correct or not.

I conclude with every wish for the continued success of your splendid journal. F. G. PEASNELL, D.R.
B.E.F.

CURIOUS CASE.

Sir,—The case of a $2\frac{3}{4}$ h.p. flat twin starting readily from d and firing evenly and regularly, with the rear brush-lder on the magneto (Thomson-Bennett) in position, but void of carbon brush, seems to merit notice.

This occurred recently with a borrowed machine. The ush had been deliberately removed—a curious precaution ich missed its object—and I verified this, to my surprise d that of the canny one, on returning.

Could you give this the benefit of your publicity? I am t guessing, as the end of the high-tension wire could not ve closely approached the collector ring.

Flanders. HAROLD C. COUSINS, R.M.A.

POST-WAR IDEAL.

Sir,—I agree with "S.C.C." in every respect as to the tual type of engine, but think a series of powers from out 900 c.c. to 400 c.c. in range would be advisable, a vo-speed gear box, with fairly close gear ratios, and nstant mesh.

I myself favour the elliptic springing and cantilever forks, ntrol by twist grip, but not by wires inside the handle-ars. I nearly got "bent" by one of this type rusting up. mple adjustment should be allowed both for gear box and ack wheel to keep the chains as requisite.

Also I think that solo, as a method of getting about, is referable to sidecar, and has the advantage that the frame an be made much lighter. C.G L S.

R.N.

ONG V. MEDIUM STROKE ENGINES.

Sir,—I was much interested in the article by "Mohandis" n the above subject. I think it ought to dispose of the idely held fallacy that because an engine has a long stroke, *pso facto* a more powerful turning effort is exerted on the ywheels. "Mohandis" shows that the total thrust on the iston of his short stroke engine is one and a half times the hrust exerted in his long stroke engine.

But the thrust in the long stroke engine is applied at a oint (the big end) which is one and a half-times the distance rom the centre of the flywheels as compared with the short troke engine. Consequently the total turning effort exerted n the flywheels is the same in each instance. I have only ouched on the question of mechanical advantage or leverage quite apart from the respective frictional losses, etc), as his is the point on which I have had many an argument n the past.

I greatly sympathise with the R.A.F. motor cyclists, as I myself served for nearly three years in the old R F.C., mostly in France with artillery squadrons. I always found that we motor cyclists were never appreciated by the R.F C. like the D.R.'s in the Signals were by their corps—in fact, one of the C.O.'s under whom I served told me that "any fool could ride a motor bike." I wish I had had a chance of taking him in my sidecar round the batteries on my visits to the wireless stations (especially during the winter!)

However, after much perseverance and waiting (fourteen months to be exact) I managed to get my application through for a commission in the R.G.A., so six months ago I bade goodbye to unpleasant fatigues, guards, etc., and entered a fresh and very interesting field of work.

I expect I shall be going out again in a few weeks, but I shall never under-estimate the abilities and troubles of the R.A.F. motor cyclists whom I encounter.

I have been a keen motor cyclist for nine years, and I have read your excellent paper regularly for longer than that. May it ever flourish! CLINOMETER.

Sir,—Your contributor "Mohandis" in his article "Long *v.* Medium Stroke Engines" concludes by saying, "The secret of the popularity of the *short* stroke engine must be sought in a region inaccessible to the mathematician."

May I be allowed to express my opinion on this subject? The popularity of the short stroke engine is due to the facts that it is lighter per unit of horse-power and more compact than the long stroke engine of equal capacity. If the mathematician likes to dissect matters he will find that, theoretically, the short or medium stroke engine holds its own and to spare.

"Mohandis" compares two engines of equal capacity—one with a bore and stroke of 85 × 88, the other 69 × 132—and arrives at the conclusion that the bearing pressures due to inertia or centrifugal force are practically identical in both cases, and I would here add that both these engines, being of the same capacity, must theoretically run at the same r.p.m. in order to give the same h.h.p. Therefore, the torque is the same, and, this being so, the average load on journal or crankshaft bearings must be the same, so that we may cancel the question of bearing loads and consequent wear of bearings from the argument.

"Mohandis" proceeds to show that in the matter of "mechanical efficiency" the short or medium stroke engine scores. He then goes on to say that the long stroke engine has 11% more cooling surfaces than the *short* stroke engine.

Now "Mohandis" will perhaps correct me if I am wrong, but my impression for some time has been that the engine with the least area per unit of volume in contact with the burning gases will have the highest thermal efficiency. Therefore, it appears to me that the short, or medium, stroke engine is popular, and quite rightly so, for the following reasons:

(1.) Higher mechanical and thermal efficiencies.
(2.) It can be made to weigh less per unit of power.
(3.) Is more compact.

All of which can be deduced from the article referred to, and yet the writer thereof appears to think that the fashion in short or medium stroke motors is based on individual prejudices and opinions. J. T. CLARKE.

LEAKAGE OF MAGNETISM.

Sir,—I would like to let my fellow readers of your journal know of a rather peculiar experience I have just encountered on the road, and I trust you will excuse me if I treat of it at some length, as I believe it will be of real value to some other poor sufferer.

I am one of the few fortunates who are still permitted to ride, and am up on a $4\frac{1}{4}$ h.p. 1916 B.S.A. countershaft combination with Dixie magneto, my former mount being a 1913 $3\frac{1}{2}$ h.p. solo B.S.A., Bosch magneto, and I am a hard rider to boot. When my $4\frac{1}{4}$ h.p. was about eighteen months old, it began to get "woolly," lost power, and continually missed fire whenever a bit of hill was met. I tried all the plugs on the market, and, being an engineer by trade, I tried everything I knew about motor engines on the machine. Finally, one day after a run of about thirty miles in wet weather, I stopped in a shelter to take some Bovril, and that was the finish. No more did that cycle go, despite everything I tried. I pushed it four miles to a garage, and immediately I told the garage proprietor my trouble and informed him that it was a Dixie magneto, he asked how it was driven. On telling him that it was a steel sprocket wheel and chain, he told me point blank that it would never go, as the magnetism was being drained through the steel wheel, as the Dixie is made the reverse way from any other. He had had to convert seven other machines for the same defect.

He was good enough to offer me the use of a Bosch off another machine, and to get mine done up and a brass wheel made instead of the steel wheel. The first kick made it roar with the Bosch, and, whereas my consumption had dwindled down to forty-five miles per gallon with the Dixie, I got then about eighty miles with the Bosch.

I have had a brass wheel put on the Dixie, and the magneto is improving, and seemingly getting stronger, but there is not nearly the same flexibility about the running of the engine as with the Bosch magneto. The peculiar thing was that when I took out the plug and tested it on the cylinder I got a spark, though not a fat one, but immediately I tried it in the cylinder the compression seemed too strong for the spark to jump.

This experience has cost me a few pounds, and I would advise anyone who fancies that his engine, driven by a Dixie magneto, is going "woolly," to look to the drive, if it be steel or brass, as the brass wheel stops the leakage of the magnetism through the Dixie shaft. Perhaps the Dixie or B S.A. people may have something to say in reply to this.

Kirkcaldy. W.A.

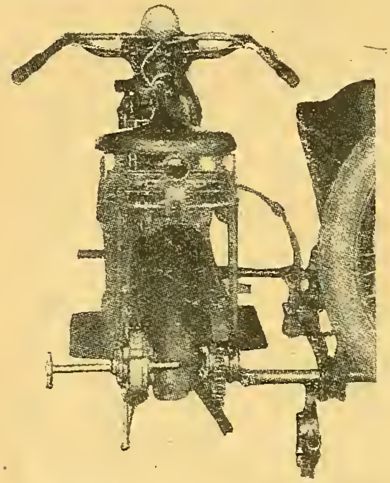
SUMMARY OF CORRESPONDENCE.

A Birmingham reader who works on munitions and has lost a son in the war suggests that *bonâ-fide* night workers who worked through the Easter holiday should be allowed to use their motor cycles at Whitsuntide to obtain a little fresh air and change of scene, and that a licence should be granted to them for that purpose at a cost of 2s. 6d. or 5s. on production of a note from the firm for which they work.

INTERCHANGEABLE WHEELS FOR "LIBERTY" MOTOR CYCLES.

INTERCHANGEABLE wheels form part of the specification of America's standardised military motor cycle used for sidecar work, a spare wheel being carried in the sidecar.

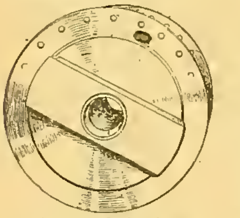
The chief problem in connection with the design of such a demountable wheel is, of course, to provide means for the transmission and braking mechanism in the rear wheel. All the wheels have annular ball bearings, which denotes a new departure in motor cycle construction in America.



The rear of the American "Liberty" motor cycle, with wheel detached. The brake, sprocket, and chain remain in place. Note central bolt partly removed.

There are essentially three parts to the rear wheel construction, *i.e.*, the central part which forms the hub, the left-hand part which carries the driving mechanism and is supported in the left-hand chain stay, and the right-hand part, which carries the brake drum, and is supported in the right-hand back stay.

The central part consists of an outer hub shell mounted on two annular bearings in a sleeve. The hub shell has an inward flange at one end, and a ring nut is screwed into it at the other end. The flange and the ring nut have grooves for felt packing, so as to keep dust out of the ball bearings and retain the lubricant. The ball bearing at the right-hand end of the hub shell has both the inner and the outer race clamped tightly, and therefore will take thrust loads, whereas the outer race of the left-hand bearing is free in the shell.



Showing hub of interchangeable wheel, with spindle removed.

Each of the side members of the hub construction also consists of an outer shell and an inner sleeve. In the case of the left-hand part the shell is supported on the sleeve by two adjacent ball bearings, while the right-hand part has one ball bearing only.

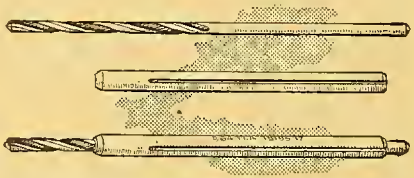
The driving connection between the central member of the hub construction and the two outer members is secured by the former having a dog or key transversely across its face at each end, and each of the outer members is provided with a corresponding groove.

The whole assembly is held together by means of a central bolt. When this bolt is removed the wheel can be drawn laterally from the two end parts.

The rear guard of the machine is hinged. It is claimed that a wheel may be changed in less than a minute.

A DRILL PROTECTOR.

ANYONE who has used drills of small diameter knows how easily these bend and break, especially when they are of more than average length. He will therefore welcome the little device put on the market by the Central Drill Protector Co., Holborn, E.C.1. This consists of a brass tube, which fits very closely to the drill near its tip, and has a slot cut from the bottom for about two-thirds of its length, thus allowing it to be compressed in the drill chuck sufficiently to grip the drill firmly. The protectors are made in various small sizes up to $\frac{1}{8}$in., and users of hand drills should find them a great economy.



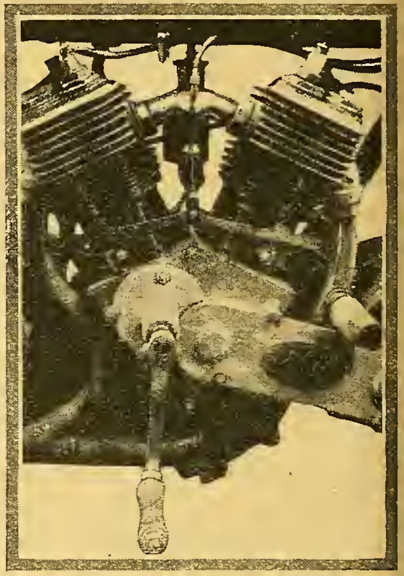
Showing how the drill protector fits over the drill.

A HANDLE STARTER FOR ZENITH MOTOR CYCLES.

THE accompanying photograph and description show how the difficulty of starting the big engine of a Zenith variably geared machine was overcome. To owners of Zenith models that lack a clutch and countershaft, this idea will make special appeal. The device is patented by Mr. H. Broadway, of High Wycombe, who describes the arrangement as follows:

The starter is operated in a similar manner to the starting handle of a car, and the engagement is secured by the following means. The existing cam wheel is used, having an extended shaft of a diameter of not less than $\frac{5}{8}$in.

The length of the shaft would need to be approximately $1\frac{1}{2}$in. long. The shaft is drilled and a $\frac{3}{16}$in. pin is inserted, which provides the medium of engagement of the starting handle. A suitable bush is fitted in the timing case, in which the shaft would run, and a quick release spring is fitted for throwing the dog clutch of the handle out of engagement. The whole is covered by a neat aluminium casing, which prevents the ingress of dirt. The casing is about 4in. in width at the flange, and tapers to a diameter of $1\frac{1}{2}$in. at the portion where the handle enters the cover. The entire projection from the timing case is approximately 4in. The handle is constructed to fold back neatly out of the way.



A patented device for the starting of old pattern Zeniths by means of a handle fixed to an extension of the camshaft.

This device could be adapted to suit almost any type of machine, and the expense of production would be quite small. The method of operation is such that a sure and easy start is obtained with a minimum of exertion. It is hoped to put this device on the market.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

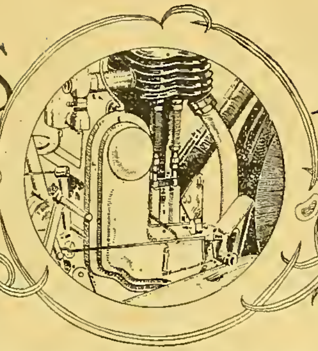
The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

CHEAP AND USEFUL.

NOW that we all do our own repairs, there may be some who will be interested to hear that a trip to one of those vermillion 3d. and 6d. stores on the American plan (which sell everything from dream books to rubber heels) might pay them. For a derisory sum one can obtain a hammer, centre and cotter-pin punches, files (flat, half-round, and triangular, medium and smooth-cut), cheap brushes, most useful springs, any number of bolts, hinges, and what-not, black weatherproof hats as effective as a sou'wester for the passenger, and quite good enough for occasional use, and, *mirabile dictu*, a perfectly practicable hacksaw—this last 6d., and really excellent.

QUESTIONS AND REPLIES



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Petrol for Use when on Leave.

Please inform me if there is any possibility of obtaining a petrol permit when on leave, and, if so, how much petrol is obtainable?—B.W.H., Lt. A.S.C. (B.E.F., France).

You should apply to the Petrol Control Department, 19, Berkeley Street, London, W.1, if possible at least a fortnight before you obtain leave. You will then in all probability get an allowance of two gallons for a motor bicycle and a permit to use it when on leave. If you cannot write well in advance of your leave, it is desirable to apply personally when coming home on leave.

Joining the Army as a D.R. Sale of Motor Cycles to the Government.

Please inform me if there are any vacancies for despatch riders in the Royal Engineers or in the Motor Transport, A.S.C. What qualifications are wanted to join either? Are the Government authorities buying motor cycles from private owners?—L.W.

Your proper course will be to apply to the nearest recruiting officer, who will give you the requisite information and state the qualifications. The Government are not buying motor cycles from private owners at the present time. This was only an emergency measure at the beginning of the war.

Aids to Cooling.

Will you please help me with a few queries concerning a 1914 a.c. 8 h.p. Morgan-Jap with *non*-adjustable tappets? (1.) Should I obtain any advantage by fitting Harcourt radiators (I go long fast runs)? Could I get them to fit my engine? (2.) About the tappets. I have been accustomed to the adjustable type, and the non-adjustable tappets on this J.A.P. engine rather worry me. I do not mind the noise much, as I have a fairly open exhaust, but I want to be sure the "lift" is not late. (3.) I have had a new B. and B. pilot jet carburetter, and find the makers' instructions as to setting rather complicated. The engine starts well on opening the pilot jet, and I am not particular about slow running with throttle closed. Is it all right to use the pilot only as a starter?—M.D.

(1.) Yes, we think Harcourt radiators would be an advantage. (2.) The tappets are adjustable by means of loose plates or discs of steel, and are quite satisfactory. We can suggest nothing better. (3.) Allowing the engine to tick over does not necessarily waste petrol, unless you allow the engine to run for any length of time with the car at rest. The adjustment of your carburetter appears correct. The pilot can be used as a starter.

Electrical Queries.

(1.) I have an accumulator, four volt twenty ampères, slightly sulphated. I propose to empty out the acid, rinse, and fill with distilled water, having dissolved in it a small lump of common soda, then to charge lightly till the sulphate falls off to the bottom of the case. Finally, rinse, add acid, charge, and expect to have the accumulator in perfect condition again. Is this feasible? (2.) Can I rectify alternating current for charging by passing it through a series of aluminium plates in a strong salt solution? Plates $\frac{1}{16}$in. apart; wires connected to the outside plates only. Current 200 volts alternating to 4 volts 1½ ampères continuous.—W.F.J.

(1.) The treatment suggested might be successful, but the result is uncertain, and it would seem to be unnecessary considering the battery is only slightly sulphated. In that case, all that is required is a long slow charge, say half ampère, continued till the cell gases freely and the voltage is well up. This can easily be arranged from a house lighting circuit in series with a lamp or two lamps in parallel with each other. If all the sulphate does not disappear after the first charge, discharge at the normal rate and repeat the slow charge. (2.) The two problems of rectifying a current from alternating to continuous and transforming it from a high voltage to a lower one seem to be confused in this query. A resistance or transformer is necessary in the latter to bring the voltage down, and for this purpose a bank of lamps may be used just as in charging from direct current mains. The simplest form of rectifier consists in two plates—one aluminium and the other lead or iron. These plates are put in a glass or other suitable jar filled with strong alkaline solution, such as common soda or potash. This rectifier is wired in series with the lamp resistance and the iron or lead pole joined to the negative terminal of the accumulator. Current will then only flow in the required direction.

Licences.

In your edition of February 28th, you informed the purchaser of a second-hand motor cycle of the conditions under which he might obtain petrol for testing it. Will you kindly tell me if, for such a purpose, it would be necessary to (1) take out a driving licence (5s.) and (2) register the machine?—R.D.A.

It would be necessary to take out a driving licence (5s.), and, really, you ought to register the machine (5s.), as this step must be taken some time or other, and when once done the registration lasts as long as the machine is in your possession, also when the machine has been used on the road, you render yourself liable for taxation.

Disc Wheels, etc., on a Morgan.

(1.) I have disc wheels on my machine, and in mending a *front* tyre puncture I remove the outer disc, but the inside one is wired on. How can one get leverage enough to get the covers *off* with this disc in position? Usually I used to force over the lever to almost a right angle through the spokes. To remove the inner disc would be a long job also. (2.) Will you please tell me how to take up any side play in the front wheels? (3.) Is it advisable to carry a butt-ended tube for the rear wheel, and cut the old one out and have it re-jointed (in case of a bad puncture)? (4.) Do you consider Duco valve stem lubricators would be any real advantage on this engine? (5.) Is it practical to remove one cylinder at a time, and so leave induction pipe and carburetter standing?—G.A.R.

(1.) We cannot see that the inside disc interferes with the removing or putting on of a cover in the slightest degree. If the correct levers are used and a third hand or fitter's "stop," there is certainly no need to turn the lever so far as you describe. (2.) Remove the dust cap, and when this is done the nut and adjusting cone will be disclosed. The bearing is then adjusted in the ordinary manner. (3.) The idea of using a butt-ended tube is an excellent one, and we should advise you to carry one. If you like, you can remove your present endless tube and get it made into a Rich detachable type by the Thames Rubber Co., Ltd., 199, Upper Thames Street, London, E.C.4. (4.) Yes; the valve stem lubricators prevent air leakage at worn guides and lubricate and quieten the valve motion. (5.) Yes; but when the engine has to be dismantled there is no reason why you should not remove the whole induction pipe and carburetter. There is no advantage in leaving the carburetter standing.

Why a V Twin Magneto has no Distributer.

(1.) If a spark can be obtained at the plug points, twice per revolution of the armature, why is a distributer necessary for a car? It seems to me that there is a continuous current from the slip ring. (2.) Is a V twin of the J.A.P. type timed from the front cylinder (No. 1), and is a distributer used in this case, and how is the firing of No. 2 cylinder obtained so soon after No. 1 unless a continuous current is given out by the magneto, and not only at each maximum position of the armature?—G.R.T.

(1.) The construction of a four-cylinder car magneto contact breaker provides two sparks every engine revolution. In the case of a four-cylinder car, these sparks must be conducted one to each of the two cylinders in turn each revolution, and the distributer serves this duty. (2.) A distributer is not used in a V twin motor cycle engine because the armature revolves at half engine speed, and the contact breaker allows for the provision of a spark for each cylinder, because there are two cams, and contact is made and broken twice for each armature revolution. It does not matter whether the magneto is timed from the front or from the rear cylinder. Incidentally, the rear cylinder is conventionally described as No. 1. (See also next reply.)

Direction of Magneto Rotation and Width of Contact Gap.

(1.) Does the magneto of the average 3½ h.p. single turn at half engine speed? (2.) That is, does a spark occur at the plug at every maximum position of the armature, *i.e.*, twice per complete revolution, and if this is more often than every compression stroke there must be an unused spark occurring at the plug? (3.) When the current has been generated in the primary winding, and until the contacts break, does it complete its circuit through the magneto to the rocker arm, across the points (which at this time are together), and so to the primary winding again, and on the points breaking with the armature at its maximum position the complete circuit, *viâ* the magneto, is destroyed, and the sparking current is forced to complete its circuit *viâ* the plug? (4.) But if this is so, and that the points (platinum) are only for destroying or breaking the magneto circuit, why is it necessary that they should only open .4 mm. as in practice? Is it on account of their closing in time for the next maximum position of the armature?—G.R.T.

(1.) Yes. A magneto of a single-cylinder four-stroke engine revolves at half-engine speed. The two-stroke single-cylinder magneto revolves at engine speed. (2.) The spark only occurs when a break occurs at the contact breaker. Consequently, there is not an unused spark at the plug at any time. (3.) Yes. (4.) The distance .4 mm. is to prevent undue hammering of the points. If the distance were much greater the hammering action would be increased. Another reason is that if the gap were greater the period of contact might be reduced too much.

Making an Engine.

(1.) I have a cylinder 76 mm. bore and 7⅛in. long (internal measurements). The piston is 3in. long. The valve chambers are 1⅝in. diameter and ¾in. deep. What will be the best compression ratio I can get? (2.) What will be the best lengths to make the connecting rod and the stroke? (I am in a position to get materials to make up this engine, hence my asking your advice.) (3.) Would Hoffmann ball bearings, pattern L10 or LS10, be suitable for main bearings? They are 1in. bore and ⅝in. on face. (4.) If the answer to above is negative, can you recommend phosphor bronze for plain bearings? (5.) What c.c. and h.p. should this engine develop, assuming it was made as well as by a first-class motor firm? (6.) What would be approximately the weight of a flywheel for this engine for fairly fast work on the road? Is it not possible to have two outside flywheels, say, a foot in diameter, one at each side, with the drive mounted inside one of them?—L.W.

(1.) The best compression ratio depends on the use of the engine and the design of the cylinder. You say later in your letter you require the engine for speed work, therefore you will want fairly high compression; but, on the other hand, the design of your cylinder may be such that it will not stand this, and, moreover, the interior form may also present difficulties in this direction. It is extremely difficult to advise you without an examination of the cylinder itself. Probably, if you arranged for a ratio of 4½ to 1 you would be safe. (2.) The of course, depend on a number of fact which you do not mention, and in c nection with your scheme generally, first thing you should do is to plan the engine roughly on paper and see h the parts work in. You will proba find when you have done this that s dimensions as those for which you will settle themselves by reference other matters. (3.) The bearings mention are rather light for the purp but would be preferable to plain be ings. (5.) The c.c. depends upon stroke selected; the horse-power upon formula used. By R.A.C. formula y cylinder would be rated at 3½ h.p. The weights of the flywheels might anything from 10 lb. upwards. Outs flywheels, of course, could be used.

To Overcome the Difficulties Imposed by the Paper Shortage

□ □ □

At the present time, owing to the shortage in the supplies of paper for printing purposes, the production of newspapers is beset with difficulties, but by eliminating chance sales—with the consequent risk of copies remaining unsold, which leads to paper being wasted—it is hoped that the weekly demand for *The Motor Cycle* can be met, and all *regular readers* supplied with copies.

To those readers of *The Motor Cycle* who have given a definite order to their newsagents, the publishers tender their appreciation and thanks.

To those who have not yet done so, the publishers again make their urgent request that a definite order be placed at once.

Please give an order for "The Motor Cycle" to your Newsagent To-day.

Lubrication.

My motor cycle is a two-sp Allon. The country here (Henl on Thames) is very hilly, but to a fortnight ago I was able tackle all the hills on top g without the least trouble. In fact never opened the throttle fully. Ab a fortnight ago, on the eve of a l run, I found the following conditio (1.) The engine ran passably on level, but wanted the throttle m more open than previously for same speed. (2.) It knocked very m for ten yards when changing fr bottom to top or when picking (3.) It misfired and stopped sudde when opening the throttle fully at bottom of a hill when on top gear. It would not take any hill on top, l needed bottom gear. (5.) The sp was very slow compared with its pre ous speed. After a struggle to st it, and after a run of half a mile, suddenly shot away and climbed very stiff hill very fast on top ge After a ten minutes' stop it returr suddenly to conditions 1 to 5. T last few weeks I have used F Castrol lubricating oil, being unable obtain any other. The jet is compos of seven jets, and enables me to only about 40 m.p.g. The carburet is an Amac. I have never taken t engine to pieces. Would you kin tell me what, in your opinion, is wro with the engine? Is it *(a)* the oil, lack of grease in the gear box, *(c)* broken piston ring, or *(d)* too large jet?—J.M.A.F.

(a) The trouble is possibly due to t oil. Use only oil for air-cooled engin if possible. *(b)* Engine oil in the ge box. *(c)* You cannot tell this unless y take down the engine. Probably t rings are stuck up, and the engi requires to be decarbonised. *(d)* T general symptoms seem to indicate th the jet is choked, and the fact that t engine ran better on one occasion w probably because the partial obstructi cleared itself and then again chok the jet.

RECOMMENDED ROUTE.

A·J·S

THE USE OF THIS BADGE

BRITISH · ASSOCIATION OF BRITISH MOTOR AND ALLIED MANUFACTURERS

is an indication that this Firm has been accepted as genuinely British by a Tribunal of Trade Competitors

To the query of "origin"

respecting the A.J.S.—the reply of "the man who owns one" would convey—additional to its being Best British—the fact of many original design-features which are responsible for uncountable awards, and high testimony from thousands of satisfied owners.

Original design-features common to each A.J S. model include Scientifically built Straight Tube Frame; Powerful, Silent, and Vibrationless A.J.S. Engine: All-enclosed Weatherproof Chain Transmission; Kick-starter with enclosed mechanism; Special Three speed Countershaft Gear; Patent Gate Change; Handlebar-controlled Perfect Multiple Plate Clutch; Forced lubrication direct to main bearings and big-ends; Internal Expanding Rear Drum Brake; Patent Spring Forks; Interchangeable Detachable Wheels; Ample-protective Mudguards; Weatherproof finish.

Owing to our being fully engaged on supplying Government requirements, we regret our inability to accept orders for delivery at present, but suggest that you place your name on our "Waiting List" for our earliest possible attention.

A. J. STEVENS & CO. (1914), Ld.

Combines great steadiness with ample elasticity.

SATISFACTION!

"Satisfaction"—what does that mean in buying a second-hand machine? People's ideas of satisfaction vary. Let us tell you what we mean when we state that we give satisfaction. Let us reconstruct a deal, any of the 250 sales we have conducted this year:

1. **You write to us** in answer to our advertisement. Your letter receives prompt and courteous attention. You ask perhaps for our advice in choosing a mount. We give it willingly to the best of our ability, and we recommend the machine we think the most suitable to you, **not** the one that shows us the greater profit. Perhaps you ask for details of a machine advertised. You do not receive in return a scanty note saying that the machine advertised is in "good condition." Instead, you receive a comprehensive printed report—giving a detailed description of every part of the machine—the make and condition of engine, gears, tyres, carburetter, magneto, controls, etc.; the condition of plating and enamel, the maximum and minimum speed, the consumption, the engine and frame numbers for verification of date—in fact, an absolutely comprehensive and exact detailed description of every part of the machine. Write to us for the specification of any machine advertised, compare it with the specifications given by other firms, and judge us by the results.

2. **You place an order** for a machine—perhaps without seeing it. You want to receive the machine in good order; we want you to have it in good order. Therefore we have instituted a comprehensive test report. Every part of the machine is checked before despatch, and the machine is tested for ease of starting, flexibility, hill-climbing, etc. In fact, it passes as complete a test as a new machine prior to leaving the works. The mechanic who carries out the test signs a report on it before the machine is despatched, and you may rest assured that the machine will arrive complete and ready for the road in every way.

3. **You receive the machine.** We have assured ourselves that it is as perfect as can be before despatch. But perhaps after you have got it, you think you would have preferred some other type. Buying a second-hand machine is often a difficult matter if you are not sure of the exact kind of machine you want. That is where our **exchange service** comes in. No matter however perfect the machine we have sold you, we are always ready to exchange it entirely free of charge for any other of not less value on our list **within three weeks of purchase.** Thus, when you buy from us, you can be sure of getting what you want—if not the first time, then the second or third time.

4. **After you have bought the machine** our interest in you does not cease. You have become a customer of ours, and we want to keep you a customer of ours. We shall at all times be willing and glad to assist you with our advice or help in any way regarding motor cycling; we have in the past given you the best of our service, and with every new client we make, we try our best to make it a case of "Once a customer, always a customer."

5 **Present circumstances.** Under War conditions motor cycling is not easy. Restrictions abound at every turn. But, after the War, the shortage of machines will be enormous. Be wise—place your order in time. Write to us for details of how to reserve a New or Second-hand Machine of any make for after-the-War, and how to pay for it now—whilst you cannot use it—by means of small instalments. Below we give a selection from our Stock, every machine being ready for immediate delivery.

SELECTION FROM STOCK:

1.	**A.J.S.,** 1915, 2¾ h.p., 2-speed, clutch, kick-starter	**39 gns.**
2.	**ALLON,** 1916, 2-speed, 2-stroke	**27 gns.**
3.	**ALLON,** 1917, 2-speed, 2-stroke, clutch, run 250 miles	**36 gns.**
4.	**AMERICAN EXCELSIOR,** 1917, 8 h.p., 3-speed, dynamo lighting Combination	**85 gns.**
5.	**ARIEL,** 1916, 3½ h.p., 3-speed, countershaft	**49 gns.**
6.	**BAT-J.A.P.,** 1914, 6 h.p., 3-speed, 2-seater Sidecar	**39 gns.**
7.	**B.S.A.,** 1915, 4¼ h.p., 3-speed, chain drive	**45 gns.**
8.	**B.S.A.,** 1916, 4¼ h.p., 3-speed, chain-cum-belt	**53 gns.**
9.	**B.S.A.,** 1913, 3½ h.p., 2-speed, clutch	**25 gns.**
10.	**BRITISH EXCELSIOR,** 1916, 2-stroke, 2-speed, clutch	**25 gns.**
11.	**CALTHORPE,** 1915, 2-stroke, 2-speed	**23 gns.**
12.	**CALTHORPE,** 1915, 2¾ h.p., 2-speed, clutch, J.A.P.	**24 gns.**
13.	**CALTHORPE,** 1915, J.A.P., 2-speed, clutch, renovated	**24 gns.**
14.	**CAMPION-J.A.P.,** 1915, 4¼ h.p., Jardine gear-box	**37 gns.**
15.	**CLYNO,** 1915, 2-speed, clutch, 2-stroke, renovated	**28 gns.**
16.	**CRESCENT,** 1916, 2-speed, 2-stroke, very fast	**26 gns.**
17.	**CARDEN MONOCAR,** 1915, 2-speed, de Luxe, very smart	**59 gns.**
18.	**DOUGLAS,** 1913, T.T., 2-speed	**27 gns.**
19.	**DOUGLAS,** 1914, 2¾ h.p., 2-speed, clutch, kick-starter	**33 gns.**
20.	**DIAMOND,** 1916, 3 h.p., 2-speed, clutch, 4-stroke	**29 gns.**
21.	**ENFIELD,** 1915, 3 h.p., 2-speed	**32 gns.**
22.	**ENFIELD,** 1916, 3 h.p., 2-speed, as new	**41 gns.**
23.	**ENFIELD,** 1916, 6 h.p., Colonial model Combination	**72 gns.**
24.	**ENFIELD,** 1916, 6 h.p., Standard model Combination	**69 gns.**
25.	**F.N.,** 1913, 5-6 h.p., 2-speed, clutch	**29 gns.**

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns First 12 words or less 1/6, and 3d. for every ɔ words after. Each paragraph is charged arately. Name and address must be counted. ies discounts, conditions, and special terms regular trade advertisers will be quoted on plication.

Postal Orders sent in payment for adverements should be made payable to (& Co.) FFE & SONS Ltd., and crossed

All advertisements in this section should be companied with remittance, and be addressed the offices of "The Motor Cycle," Hertford eet, Coventry. To ensure insertion letters ould be posted in time to reach the offices of The Motor Cycle," Coventry, or London (20, dor St., E.C.4), by the first post on Friday rning previous to the day of issue.

All letters relating to advertisements should ote the number which is printed at the end of cb advertisement, and the date of the issue which it appeared.

The proprietors are not responsible for clerical printers' errors, although every care is taken avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be dressed to numbers at "The Motor Cycle" Office. en this is desired, the sum of 6d. to defray the cost of istration and to cover postage on replies must be added the advertisement charge. Only the number will appear the advertisement. All replies should be addressed No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons y deal in perfect safety by availing themselves of our posit System. If the money be deposited with "The tor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the ods is three days, and if a sale is effected we remit the ount to the seller, but if not we return the amount the depositor, and each party to the transaction pays riage one way. For all transactions exceeding £10 in ue, a deposit fee of 2s. 6d. is charged; when under the fee is 1s. All deposit matters are dealt with at ventry, and cheques and money orders should be made yable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an lication that the advertiser is willing to avail himself of e Deposit System. Other advertisers may be equally sirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no swer to their enquiries are requested to regard the ence as an indication that the goods advertised have ready been disposed of. Advertisers often receive so any enquiries that it is quite impossible to reply to each e by post.

Accumulator Electric Lighting

Complete Set, 100/-

For Solo Machines. This set contains head lamp and tail lamp of the latest approved design, with adjustable handle-bar fittings. The box to fit on the top tube contains a 4-volt accumulator and a switch, giving sufficient light for the two lamps for approx. 10 hours at one charge. It, without doubt, fills a long-felt want for solo machine lighting.

Douglas.

1912 2¾h.p. Douglas, 2-cyl., clutch, Bowden trols, 2 speeds, excellent condition, tyres goo Carleton and Tulloch, 15a, Down St., Piccadilly, 'Phone: Mayfair 1037. [0

DOUGLAS 1915 4h.p. Combination, 3 speeds kick start, all accessories, bargain, £60; four 1 2¾h.p. models, all in excellent condition, from £32 —Maudes' Motor Mart, 100, Gt. Portland St., Lon W.1. Tel.: 552 Mayfair. [5

1917 4h.p. Models A. and B. Douglas, 2¾h.p. M W., also U. and V. 1916 specification, absolu new; immediate delivery against Priority Permit doctors, farmers, war and munition workers.—How where to apply, full particulars, write Douglas Special Robinson's Garage, Green St., Cambridge. [5

Enfield.

1914 3h.p. Enfield, 2-speed, nice condition; £2 86, High Rd., Lee. [5

ENFIELD 3h.p., 2-speed, twin, overhead val Model 140, new, run 80 miles; 50 gns.— L6,207, c/o *The Motor Cycle.* [5

1916 Enfield Combination, all brand new Palmer ty Lucas lamps, speedometer, perfect conditi £70.—Grove, Llanthony Abbey, Gloucester. [X4

ENFIELD, 3h.p. 2-speed twin, £57/10; ditto spe G.T. Model, £57/10; delivery from stock.—Ex Motor Cycle Co., Ltd., Bath Rd., Exeter. [3

1916 Enfield Combination, 6h.p., lamps, horn, sp did condition throughout; £75.—Elce and 15-16, Bishopsgate Av., Camomile St., E.C. [0

1915 3h.p. Twin Enfield, Lucas lamp, rear la horn, and tools, done 2,000 miles only, gua teed as new; £29.—Missin, Cottingham, Hull. [X4

ENFIELD Late 1915 Combination, £75; 1916 c bination, splendid order, 80 gns.; E.P. or changes.—The Service Co., 292, High Holborn, W. [X4

2¼h.p. 1916 Enfield, 2-stroke, 2-speed model; ha little machine, mechanically sound as n £37/10; guaranteed.—Wauchope's, 9, Shoe Lane, L don. [5

ENFIELD 3h.p. Twin, late 1915, little used, new coachbuilt sidecar; £48, including lan tools, spares.—Gregg, 19, Clifford Rd., E. Finch London. [5

ENFIELD 6h.p. Combination, July, 1916, mile about 2,000, Lucas lamps, latest Enfield scr not used since October; any examination; £75.— Bromsgrove Rd., Redditch. [X4

ENFIELD Combination, 1913, 6h.p., complete w lamps, horn, speedometer, and full kit of to thoroughly overhauled; best offers.—S. Brooke, 4, W acre St., Deighton, Huddersfield. [5

6h.p. Enfield Combination, 1916 model, with dyna lighting set and speedometer, has not been u much, and is in beautiful condition; will deliver road up to 60 miles to purchaser; £79; at Mansfiel Box 1,939, c/o *The Motor Cycle.* [X4

FOR Sale, Royal Enfield motor cycle and coachb sidecar, 6h.p. twin-cyl. J.A.P. engine, late 19 self-starter, electric lighting, Hans Renold chains, m age 2,500, perfect condition.—Price and full particul apply, Moody Bros., Blyth Motor Garage, Blyth, No umberland. [0

6h.p. 1915 Royal Enfield Combination, Lucas dyna lighting set included, £77/10; also a 1917 mo combination, fitted with all accessories, £87/10; 1 model combination, £35; also a 3h.p. 2-speed solo mo £32/10; all guaranteed.—Wauchope's, 9, Shoe La London. [5

F.N.

2¾h.p. F.N., C.A.V., B. and B.; £12.—80, Gra moor Rd., Higher Openshaw, Manchester. [X4

Grandex.

GRANDEX-PUP, 2-speed gear, in good order; £ or will exchange for lathe or milling machine.— Goldhawk Rd., Shepherd's Bush, London. [5

Harley-Davidson.

1915 7-9h.p. Harley Combination, very good ord £54.—86, High Rd., Lee. [5

1917 Harley-Davidson, De Luxe sidecar; of wanted.—27, High St., Doncaster. [5

HARLEY-DAVIDSON Combination, 1916 model, beautiful condition; £65.—Pepper and Co., Si St., Enfield. [5

HARLEY-DAVIDSON Combination, 1915, elec model, Swan sidecar, excellent condition; £6 46, Hillcrest Rd., Acton. 'Phone: 1578 Chiswick. [5

1915 Harley Combination, in excellent conditi mileage under 3,000; this outfit is a good gain at £65.—Whale, 56, Townshend Rd., N.W.8. [X4

1917 Harley-Davidson Combination, 7-9h.p., n model, lamps, horn, unscratched condition; £1 —Elce and Co., 15-16, Bishopsgate Av., Camomile E.C.3. [0

HARLEY-DAVIDSON, single-cyl. 2-speed mo £68 model, never used; what cash offers? or change Ford modern car.—Buckingham, Rindal Chelmsford. [5

Balance and Torque.

An interesting discussion has been started in our pages on the respective merits of balance and torque. This was begun by a contributor who in our issue for March 21st sang the praise of the vertical twin with a single crank throw. As our readers know, this engine has even firing intervals, one per revolution, as in the case of the flat twin or single two-stroke. On the other hand, the balance is the same as in a single-cylinder engine, or perhaps slightly worse, owing to the fact that the double number of reciprocating parts, which rise and fall together, must be of greater weight. There is, however, no couple which is found to excess in the vertical twin with cranks set at 180°, and in a less degree in most flat twins, the exceptions being those engines which have a three-throw crank and a forked connecting rod. Some flat twins are built with narrow roller bearings which enable the cylinders to be almost in line and consequently reduce the couple to small proportions, but nevertheless it is there.

Our contributor compared this engine with both the V and flat twins, very much to its advantage in each case. Some of the claims may be admitted. It has more even firing than the V twin, is more accessible than the flat engine, and more easily fitted into the usual diamond frame. Also we may grant that it is better cooled than either of its competitors. The disadvantages are stated to be greater width and less perfect balance, but it is suggested that in the case of the V twin this disadvantage is theoretical only. This is incorrect—it is actual; the least possible unbalanced mass being something like half as much again as in the V twin, depending upon the cylinder angle of the latter. We refer, of course, to the angles generally in use, say 60°: in a 90° twin the difference is much greater, for a 90° twin can be very well balanced.

The writer then contends that torque is better than balance, and gives as an example a twin with one cylinder firing intermittently. This can hardly be considered a good argument, for it is not likely that any machine will be comfortable to ride when it is running imperfectly. The balance is not affected, but the torque is. Granted! But similar discomfort might ensue were the balance to be entirely upset and the torque allowed to remain constant.

Another contributor (May 2nd) contends that this discomfort is due to the snatch which is naturally present with a light flywheel, and says that the more even the firing impulses the lower may be the effective weight of the flywheel. This is true in part only, and that is when a given number of explosions are taking place per minute. The minimum flywheel weight must depend upon the longest interval between explosions. Thus a lighter flywheel can be used on a V twin than on a single, and a still lighter one on a flat twin. Suppose the engines to be running at 1,000 r.p.m., the firing intervals will be .12 second in the single, .07 and .05 in the 60° twin, and .06 in the flat twin. As the longest interval controls the situation, the flywheel weight of the V twin must be calculated for .07 second.

With regard to torque, there seems to be some confusion between evenness of firing interval and rapidity of explosions. Would those who favour evenness of torque assert that the torque of a single is superior to that of a V twin with its slightly uneven intervals? If so we cannot agree.

Of course, torque may be greatly improved by increasing the weight of the flywheel, but in motor cycle practice, as distinct from the stationary gas engine, there is a limit in size and weight which is very soon reached; moreover, while a heavy flywheel improves the steady pulling of an engine, it detracts very much from its powers of rapid acceleration, which is not required in a stationary engine.

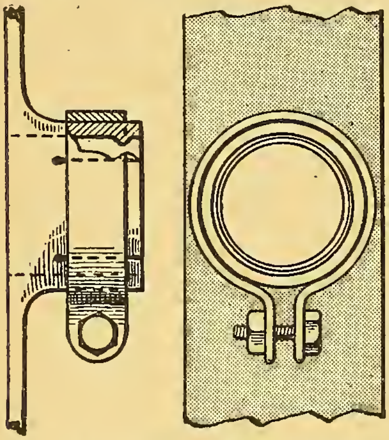
Our first contributor returns to the attack in our Correspondence columns, but we should like to have the views of other readers. The subject is an interesting one, and doubtless there is much to be said on each side.

An Index to the advertisements in this issue will be found on the page facing the back cover

IDEAS: Useful and Ingenious.

REMOVING MAGNETO BEARING.

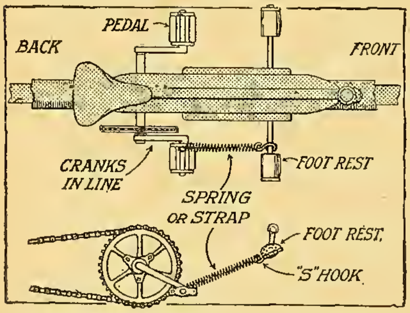
I RECENTLY had difficulty in removing the hardened ball race from the spindle in the bearing of a well-known magneto. The sketch of a tool made for the purpose almost explains itself. A split boss is shown with lugs to rest on the vice jaws, the boss being bored with a bead to spring into the annular groove of the ball race. A clip ring holds the boss in position. The spindle can then readily be knocked out.—J. W. Riley.



A tool for removing a ball race in a magneto.

SPRING FOOTRESTS.

MOTOR cycles with pedalling gear usually have only one pair of footrest, and these are generally placed too far forward to afford really comfortable support. One or other of the pedals may also be used as a footrest, but these also are not very suitably placed for this purpose. The writer has effected a radical improvement by unkeying the combined chain wheel and crank and turning it to face forward, thus bringing the pedals in line instead of at 180°. The chain wheel crank must be the one that is unkeyed and fixed in the new position.



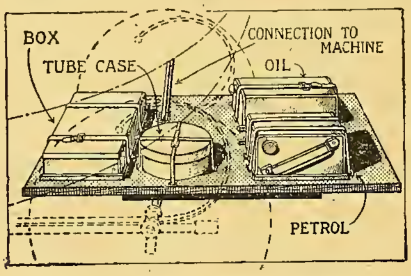
Showing how the pedals were utilised to form comfortable footrests.

A stout S shaped hook is secured to the pedal on the chain wheel side, and a heavy and springy piece of leather strap is cut to the right length to connect the pedal to the front footrest bar. The result is to support both pedals at such an angle as to afford all the comfort of an extra pair of footrests, plus the advantage of a certain amount of "give" obtainable by the use of slightly yielding leather. Alternatively, a very strong coiled spring can be incorporated to produce the same effect with, if need be, slightly more "give." The strap or spring can be detached in a moment when the engine has to be started up on the stand. It is impossible to wheel the machine backwards without first detaching the strap.—J. W. G. Brooker.

SIDECAR REFINEMENTS.

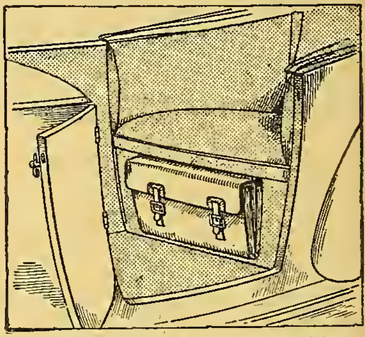
AS most sidecars are deficient in room for carrying spares, etc., perhaps two little fittings which I put on my machine would interest many sidecar enthusiasts.

First of all, I obtained a small waterproof schoolbag of the shoulder strap variety. This was placed on the front portion of the seat behind the passenger's legs, and, as my car was a wicker one, the straps were passed through the wicker and buckled up tightly beneath the sidecar, thus keeping the satchel in place. If a coachbuilt car, it could be tacked to the wood. Quite a lot of small things, such as plugs, maps, gloves, small spanner, etc., can be carried.



Showing how the luggage grid is bolted in position on the chassis.

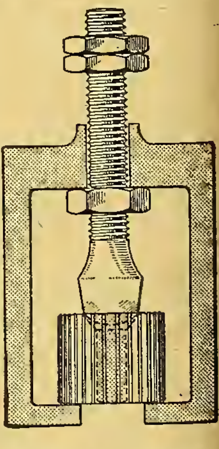
I then made a luggage grid extending right underneath the sidecar, and projecting out at the back for about eighteen inches. I obtained a piece of strong board the width of the chassis between the springs, and length as stated. This was bolted to the chassis by two pieces of strip iron, bent to fit round the chassis tubes, and extending the whole length of the board for strength. The board was then covered with a piece of rubber matting, or linoleum would do. A narrow wooden beading was put round the edge of the board to make it neater. A small lock-up box was bolted to the board beneath the car to carry spares, such as valves, etc. On the opposite side of this a leather air tube case was screwed. Various slots were cut in the front portion of the board extending behind the car, to take straps for luggage, etc. When the grid is not required for a suit case, a tin of oil and one of petrol were easily carried on it.—W. Robb.



The waterproof school bag in position.

REMOVING A TIMING PINION SCREW.

WHEN taking down a Triumph engine, it is often an extremely hard job to remove the screw that holds the timing pinion on the mainshaft. By following the method as shown in the sketch, the work is fairly straightforward. The frame of a small wheel puller is used, the centre screw being removed. In its place a short screwdriver blade is fixed, the reverse end of which is screwed for about 2in. This screwdriver should be a perfect fit in the slot of the pinion screw, and should slide easily in the wheel puller frame. Three nuts are needed, the lower one being adjusted until the blade of the screwdriver beds down hard into the slot of the screw, the two top nuts being locked. The pinion screw can then be undone easily.



A device for facilitating the removal of the timing pinion screw.

Occasional Comments by Ixion

A Novel Flat Twin.

IT used to be granted that the overhead valve flat twin was a "beast to house" from the frame designer's standpoints. I hear of a new pattern, which overcomes two nasty snags in the general layout of a motor cycle. It has o.h.v. inclined at about 45° to the cylinder axis and mounted on the upper side of the cylinders. Valves of this design demand no greater overall clearance in the frame than a side valve flat twin, as they clear the down tubes of the frame. Further, the dynamo and magneto can be accommodated above the crank case without hoisting the tank above the usual level. If dynamos and overhead valves are to become standard the flat twin may yet prove one of the most easily housed engines.

Yet Another Transmission!

ANOTHER tame inventor has had a brain wave in the way of transmissions. This is claimed to be rigid and flexible yet employs no universal joints. Imagine a square shaft, made up of thin laminæ of spring steel, and you have it. I am not going to say that this type of drive will ever transmit high horse-powers or be efficient across broad gaps, but it is conceivable that it may make a practicable, cheap, and simple variation from the F.N. type of shaft so far as small motor cycle engines with short transmissions are concerned. I like to hear of all these new ideas bubbling in the motor cycling world. Many of them may prove absolute washouts, but they indicate that originality is abroad at last, and when we reflect that the 1914 motor cycle engine was in essentials a very near relation of a 3½ h.p. Minerva which startled the cognoscenti at a hill-climb thirteen years ago, it is evident that we had got into a groove.

In My Old Age.

I USED to dream dismally in my darker moments of the inevitable day when increasing age should disqualify me from using even a baby two-stroke with an electric starter. But yesterday I was hoisted into rosier views of my octogenarian years. I met a sportsman in a cripple chair of the sort which is normally propelled by doing a kind of treadmill stunt with the fingers on dummy belt rims affixed to the spokes. At first I fancied the occupant had been gassed, for a staccato barking cough seemed to emanate from him. Closer attention showed that he had an Auto-Wheel gummed to the back axle. I fell a-musing as to what he did if the engine stopped, and imagined that he appealed to the kindliness or cupidity of the first passer-by to get a fresh push-off. As I thought deeply on the subject the staccato bark ceased. A taxi had all but rammed the sportsman at four cross roads. I turned and rushed to offer my services. [Kindliness or cupidity?—Ed.] Not needed. His fingers slithered fiercely along the belt rims and the Auto-Wheel burst into renewed song. I thank that unknown motorist. Memories of him will brighten all my future birthdays.

A Raleigh Point.

I DARESAY many readers missed an interesting detail of the Raleigh F.T. engine, illustrated on page 357 of *The Motor Cycle* for April 11th. I place no great value on the gap left for cooling draughts to percolate under the magneto to the rear cylinder. No great draught would get through: and in any case it would impinge on the inlet pocket, which probably requires warming to procure a level circumferential temperature for the cylinder head, and so avoid distortion. Oddly enough, the designer has heated the centre of the inlet pipe by enclosing it bodily in the timing gear compartment of the crank case; but as he is doing his best to cool its extremities for some reason, it must feel like a camper sitting over a fire out of doors in winter. If such an engine belonged to me I should wad up the draught gap under the magneto, lag the whole of the exposed run of the inlet pipe, and expect to get rather nice running. We have travelled some distance since I saw the first Raleigh, which had a vertical single-cylinder engine mounted over the front wheel, and driving the rear wheel by *a crossed flat belt!*

The Ideal.

AS individual tastes vary in the selection of accessories, the production of "ready for the road" machines would be unpopular. Henry Ford turns his car out completely fitted for immediate use, and, though his clients are mainly drawn from a class which cannot afford to be fastidious, numerous firms make a fat living out of supplying Ford gadgets, and their catalogues are almost as portly as the "Encyclopædia Britannica." It follows that if the Triumph Co., for example, were to turn out a 'bus ready equipped with hooter, lamp, watch-holder, and speedometer, many of their clients would specify the naked model. On the other hand, it would be the easiest thing in the world for the manufacturers' association to standardise a set of accessory mountings for the several types of bicycle, and leave the accessory people to design a variety of patterns all furnished with the same size of clip. For example, the hooter might be clipped between two collars brazed to the bar before plating or threaded on a bolt projecting from the bar, etc. The combined brackets for acetylene lamps and generators might drop over a couple of studs mounted in the centre of the bar by its manufacturer. The hub gear wheels for driving speedometers could be standardised with consummate ease, and so forth. A day's work by the technical secretary of the manufacturers' association and a two-hour meeting of the members would settle such matters.

TIMING MECHANISM.

THE FIRST OF TWO ARTICLES DEALING WITH VALVE MECHANISM.

This Instalment treats of Timing Gears in Single-cylinder Motor Cycle Engines; the Second will be devoted to Twins.

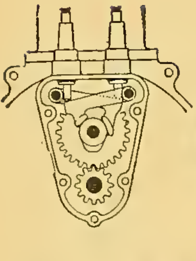


Fig. 1.—The valve gear of the single-cylinder J.A.P., using a single cam.

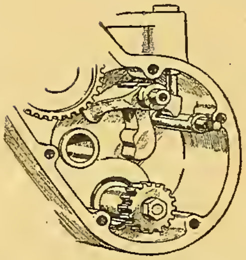

Fig. 2.—The 1915 Premier, with single cam and two rockers on one shaft.

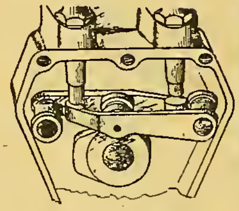

Fig. 3.—Blumfield engine, having two cams on a single wheel.

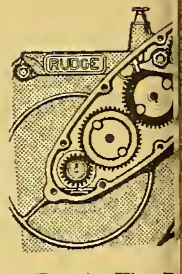

Fig. 4.—The R timing gear. Two on the last wheel c magneto drive trai

To the casual observer, most single-cylinder engines of the four-stroke type closely resemble each other. In a few cases, an unconventional disposition of the valves slightly alters the general appearance; but, generally speaking, all are so much alike that it may come as a surprise to many to know that at one particular point nearly every engine differs from its contemporaries. This is the lay-out of the timing mechanism, and, considering that its functions and the aims of the designer are almost identical in every case, the differences in applying the mechanism to carry out these functions form a most interesting subject.

One would imagine that the differences would be more numerous in the case of the twin-cylinder engines. It is, therefore, all the more surprising to find that divergences in the design of timing gears of V-twin units are considerably fewer in number than in the case of the single-cylinder engine of conventional design.

Broadly, we may divide the timing gears of single-cylindered engines into seven groups, employing the following:

(1) A single cam wheel and a single cam.
(2) A single cam wheel and a double cam.
(3) Two cam wheels with external cams.
(4) Two cam wheels with internal cams.
(5) One cam wheel and a camshaft.
(6) A camshaft for both cams.
(7) Unorthodox mechanism.

Most of these groups can be subdivided in connection with the rocker mechanism, under which heading we can make up the following groups:

(A) Those designs embodying no rockers.

(B) Those designs with "slipper" or approximately straight rockers.
  (*a*) Opposed.
  (*b*) Crossed.
  (*c*) Placed in tandem.

(C) Those with bell-crank rockers.

(D) Those with centrally pivoted levers.

From the above it will be seen that there are quite a large number of different ways of arranging timing gear on the comparatively simple four-stroke single-cylinder engine.

It is interesting to divide the best-known makes in the different groups mentioned in the first list.

In Group 1 we have the 3½ h.p. J.A.P., the 5-6 h.p. Excelsior, and the 3½ h.p. Premier.

Group 2.—4 h.p. Triumph, 3½ h.p. Rudge, 4¼ h.p. Star, 3½ h.p. Blumfield, 3½ h.p. Brown, 3½ h.p. Blackburne, 3½ h.p. T.D.C., 2½ h.p. O.K., and most of the American singles, including Indian, Harley-Davidson, Excelsi Miami, and Emblem.

Group 3.—3½ h.p. Ariel, 1912-14 3½ h Premier, 3½ h.p. B.S.A., 4¼ h.p. Jam 3½ h.p. Norton, 2¾ h.p. Orbit, 3½ h Alldays, 3½ h.p. Bradbury, 3½ h.p. and M., 3½ h.p. Humber, 2½ h.p. Calc 3½ h.p. New Hudson, 2¾ h.p. Villie 3½ h.p. L.M.C., and 3½ h.p. Rover.

Group 4.—3½ h.p. Triumph, 3½ h Sarolea, and 3½ h.p. Abingdon.

Group 5.—3½ h.p. Quadrant and 4 h M.M. (American).

Group 6.—2¾ h.p. Diamond, ? h Puch, and 2¼ h.p. Precision.

Group 7.—2 h.p. Motosacoche.

In the second list of groups s dividing the different methods of us rocker levers between the cam and tappet rods, the makes are rearrang as follow:

Group A.—1912-14 h.p. Premier, 3½ h Humber, 3½ h.p. Qu rant, and the Puch.

Group B.—(*a*) 4¼ h James, 3½ h.p. Allda 3½ h.p. Sunbeam, 3½ h L.M.C., 3½ h.p. Orb and 3½ h.p. Norton. (4 h.p. Triumph, 3½ h Blumfield, 4 h.p. St 5-6 h.p. Excelsior, a 3½ h.p. J.A.P. (*c*) 3½ h Ariel.

Group C.—3½ h. Triumph, 4 h.p. Bradbury, 3½ h Abingdon, 3½ h.p. Sarolea, 3½ h. B.S.A., and 3½ h.p. New Hudson.

Group D.—3½ h.p. Rudge (exhau valve only).

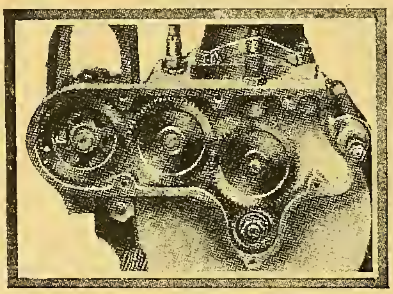

Fig. 5.—A design embodying cam wheel and camshaft. The Quadrant.

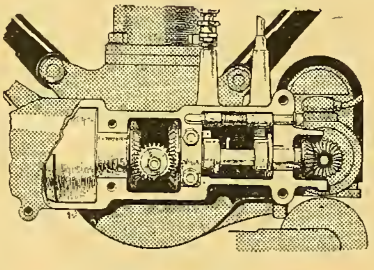

Fig. 6.—The Diamond, with cams on a bevel-driven shaft.

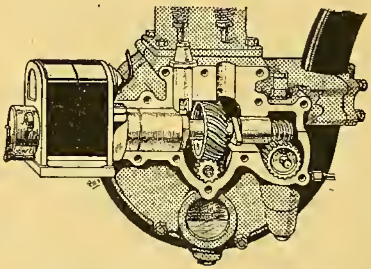

Fig. 7.—The Continental made Puch, with worm-driven camshaft.

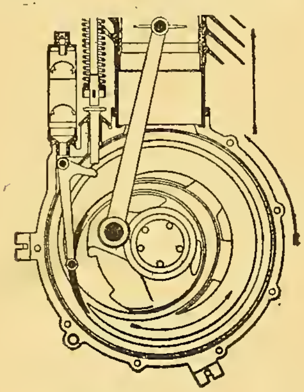

Fig. 8.—A unique valve mechanism. The single-cylinder Motosacoche

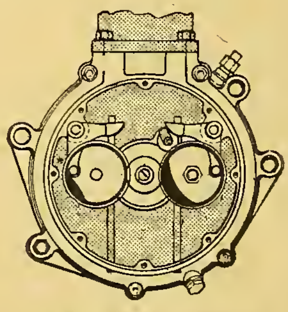

Fig 9.—The Abingdon design with internally cut cams

ONE-LEGGED MOTOR CYCLIST

WINS CHAMPIONSHIP ON

B·S·A

MOTOR BICYCLE

Christchurch, N.Z., Red Cross Motor Cycle Carnival,
23rd February, 1918.

Event 1.—LIGHTWEIGHT HANDICAP:

B.S.A. FIRST and SECOND

(WOODMAN, the one-legged motor cyclist) (KARTON)

Event 4.—MIDDLEWEIGHT CHAMPIONSHIP:

B.S.A. FIRST and SECOND

(WOODMAN) (KARTON)

Event 9.—OPEN HANDICAP:

B.S.A. FIRST and SECOND

(BONNINGTON) (WOODMAN)

In this event, B.S.A. 4½ h.p. competed against 7 h.p. machines.

RELAY RACE:

WOODMAN on a B.S.A. won the Race for his Team by beating his rival by over 600 yards.

CONSOLATION EVENT:

The accessibility of the Post-War CLYNO

Pre-war it was famed for its "get-at-able-ness." Post-war these features will emphasize that fame—

CYLINDER HEADS AND VALVES DETACHED IN A FEW MINUTES—
BACK AND FRONT CHAINS ADJUSTED IN TWO MINUTES—
ANY ONE OF THE CLYNO INTERCHANGEABLE WHEELS DETACHED AND REPLACED BY SPARE IN ONE MINUTE.
MAGNETO DRIVE—GEAR BOX CONTROL—TAPPETS—ADJUSTABLE WITH THE GREATEST EASE.
SIDECAR DETACHED IN A FEW MINUTES.

And all this will make for your greater pleasure, comfort, and convenience!

Your agent is booking after War deliveries in rotational order NOW.

Ask him about it and u

iming Mechanism.—

In all these different engines the aims f the designers have been to secure the ame ends—*i.e.*, to open the valves of eir engines as quickly as possible. Another aim should be to secure comparative silence in the mechanism employed, but this is a point where few designers have secured complete success, as many motor cycles are notoriously noisy, and in the majority of cases the timing gear and valve mechanism generally are the greatest offenders in this respect.

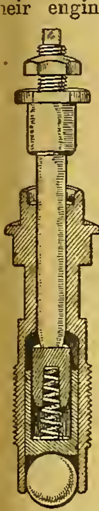

Fig. 10.—A ball-ended tappet guide with which cam rockers are not used.

The employment of a single cam to operate both inlet and exhaust valves apparently has the advantage of simplicity. In fig. we illustrate the J.A.P. design, which, t will be noted, is extremely simple. As s known to almost every motor cyclist, he lift required is not exactly the ame on both valves—the exhaust valve emaining open a little longer than the nlet valve. This difference in the ength of the lift is obtained by the hape of the rockers.

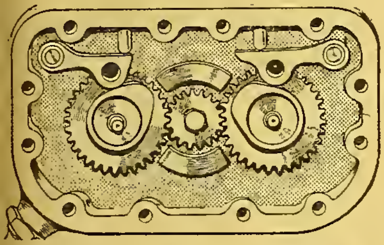

Fig. 11.—The Sunbeam engine showing opposed rockers.

This type of valve mechanism is further implified if both rockers are worked rom one shaft, as in the case of the 915-16 Premier shown in fig. 2. In this esign, it will be noted, the half-time wheel is not directly over the mainshaft inion, as in the J.A.P. design, but is laced to the side of it, and forms one f the train of gears for the magneto.

An engine with a single cam wheel having two cams side by side probably is quite as simple to manufacture as the types referred to above, as in this case, illustrated in the Blumfield engine (fig. 3), the simpler design of the rockers compensates for the work in forming the extra cam.

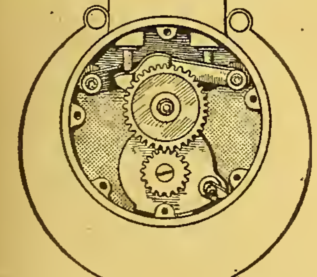

Fig. 12.—The Triumph "4," with crossed rockers.

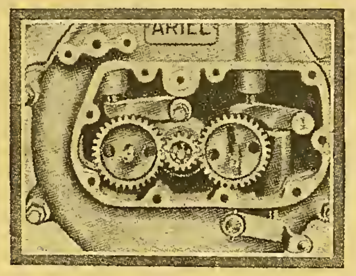

Fig. 13.—The Ariel engine, with "tandem" rockers. Note exhaust lifter lever below timing case.

The single cam wheel per cylinder is almost general practice on V twin engines, and, since it is so satisfactory, one is constrained to wonder why so many makers introduce another half-time wheel. Probably this is due to the fact that with a single cam or two cams on one half-time wheel it is impossible to re-arrange the timing of the inlet and exhaust valves independently—that is, if the timing is altered in any way, both valves are affected in like ratio. If the inlet valve is made to open earlier, then the exhaust valve opens earlier also, but with independent gears for each valve one may be changed without interfering with the other.

Single-cylinder engines with two cam wheels are more numerous in this country than any other type, and we illustrate here several examples.

Unorthodox Timing Gears.

The remaining types more or less are unconventional. For example, the Rudge engine (fig. 4) has two cams on one wheel, which is the last of a train of four forming the magneto drive. In the Villiers engine, the first and third in a train of five wheels are utilised.

There are several engines employing both a cam wheel and a camshaft. The Quadrant (fig. 5) is an example of this practice, the necessity for which is brought about by the unusual location of the inlet valve to the rear of the cylinder. The M.M. (American) engine has similar valve mechanism, the inlet valve in this case being actuated by a cam on a wheel, and the exhaust by a cam on a shaft that extends across the forward end of the crank case.

Then there are designs embodying a camshaft similar to that which is orthodox in car engines. The Diamond (fig. 6) is one of the few British examples of this practice, while the Puch (fig. 7) is a Continental design on the same lines.

There are several engines with what can be described as "freak" valve mechanism, but so few are known to be efficient that they cannot be regarded as anything more than experiments. There is one design, however, which, fitted to a small engine of well-known make, is so unconventional that it can be placed under this heading. This is the 2 h.p. Motosacoche engine (fig. 8), in which neither cam wheels nor camshafts are employed. It will be noted from the illustration that a double elliptical groove is cut in the face of the flywheel, in which runs a curved metal strip secured at the end of a long rocking bell-crank. This actuates the exhaust valve tappet, the inlet valve being of the automatic type.

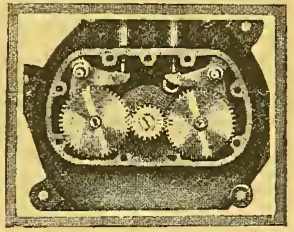

Fig. 14.—B.S.A. timing gear, using bell crank rockers.

External and Internal Cams.

Reverting to the conventional engine designs, there are two kinds of cams: the external and the internal. The external is the most popular with engine designers, but a few engines embody the internal type, among which we have mentioned the 3½ h.p. Triumph, Abingdon, and Sarolea. We illustrate this form of cam, as applied to motor cycle engines, in fig. 9.

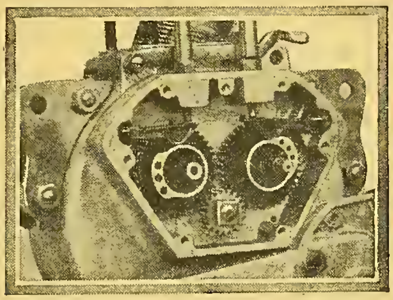

Fig. 15.—The Norton timing gear, illustrating the neat exterior exhaust valve lifter.

We have now come to the question of the different types of rockers in use, but here we can only deal broadly with the subject, as probably it is true that no two engines are alike in this respect. Previously we have divided the types into three groups, and one of these groups into four smaller groups.

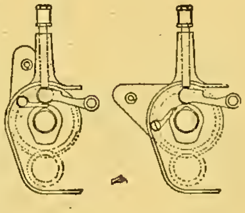

Fig. 16.—The P. and M. decompressor cam.

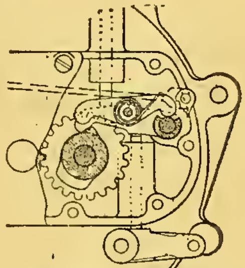

Fig. 17.—The Ariel decompressor mechanism.

Timing Mechanism.—

Under this heading it is permissible to refer to those designs which have no rockers between the cam face and the tappet rod. At first sight it would appear that the designer who eliminates the rockers has succeeded in considerably simplifying his design; but when the means employed to substitute the rockers are examined, it is admitted that there has been little, if any, saving in the cost of manufacture. Fig. 10 shows in detail a section of a tappet guide with the extra parts necessary to transmit the cam action to the tappet rod. A design such as this cannot be made so quiet in action as one embodying a rocker. The action in the former case may be likened to a train of loosely connected railway trucks being shunted as compared with the smoother effect produced with a passenger train in which all components are caused to move together. There are so many points of contact.

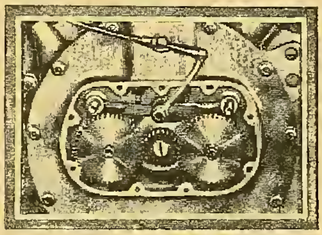

Fig. 18.—The Bradbury design, showing the neat exhaust valve lifter.

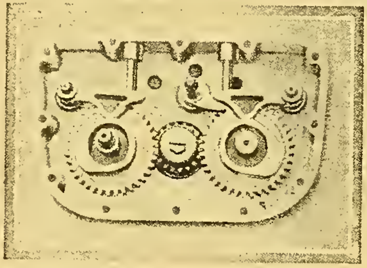

Fig. 19.—Rover timing gear, showing exhaust lifter mechanism.

In some designs, approximately straight rockers are interposed between the cam and the tappet rod; others are more complicated. There are several ways of arranging these rockers, which may be termed (*a*) opposed, as in the Sunbeam, fig. 11; (*b*) crossed, as in the Triumph, fig. 12; and (*c*) in tandem, as in the Ariel engine, fig. 13.

In many other designs, bell crank lever rockers are used, as in the B.S.A. engine, fig. 14, which have certain advantages over the slipper type of rocker. In some designs, bell crank rockers have been embodied to secure compactness.

The slipper type of rocker is not called upon to withstand very great strains, depending, of course, upon whether it is merely a member interposed between the cam and the tappet rod as the mechanism for the inlet valve (left side) of the Sunbeam engine (fig. 11), or one which is used to increase the lift, as in the exhaust valve (right side) mechanism of the same engine.

The bell crank lever actually transmits the power, taking it from the cam at one end and giving it to the tappet rod at the other. By means of the leverage obtainable with bell cranks, the movement of the tappet rod can be made larger or smaller than the cam would give if a rocker of the pure slipper type were used. But, of course, straight rockers could be used in a similar manner, though perhaps not so conveniently.

In many of the more modern designs two other functions are demanded from the timing gear, and the timing case is made to include a decompressor cam and an exhaust lifter cam. The P. and M., Ariel, Triumph, James, Humber, Excelsior, and Star are among those embodying a decompressor, while the Triumph, 1915-16 Premier, Abingdon, Sunbeam, James, Star, Alldays, and Bradbury are among those embodying exhaust lifter mechanism in the timing case.

Usually the decompressor is a third cam on the exhaust valve, which, when desired, opens the exhaust valve slightly on the compression stroke. The P. and M. device is illustrated in fig. 16, and in fig. 17 the Ariel system is shown.

The mechanical exhaust lifter is usually an idle cam, which, when turned slightly, is made to hold up the exhaust valve rocker. This will be seen in fig. 9, while a neat outside exhaust lifter is fitted to the Norton engine, shown in fig. 15. Fig. 18 shows the exhaust lifter mechanism of the Bradbury engine, while fig. 19 illustrates the Rover device.

There are two other points worthy of mention in connection with individual designs. The shaft of the half-time gear wheel on the Excelsior single-cylinde engine is carried in ball bearings—a mos unusual and perhaps very desirabl feature. This is illustrated in fig. 21.

The other unusual feature which ha many good points to commend it is th method employed on the Calcott an a few other engines to retain th train of gears within the timing cas (fig. 20). Those readers who, in remov ing the timing cover, have inadvertentl withdrawn all the gears from their inne bushes, and so disturbed both valve an ignition timing, will appreciate this littl convenience, to which so few designe appear to have given consideration.

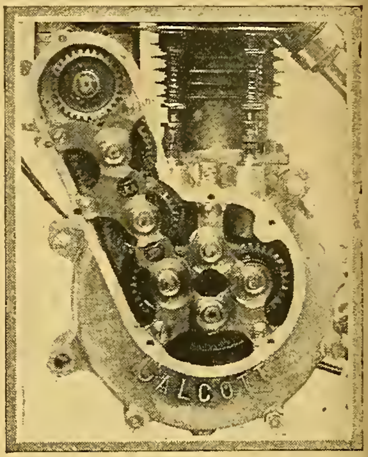

Fig. 20.—The Calcott timing gear, with means for retaining the train of gears when the cover is removed.

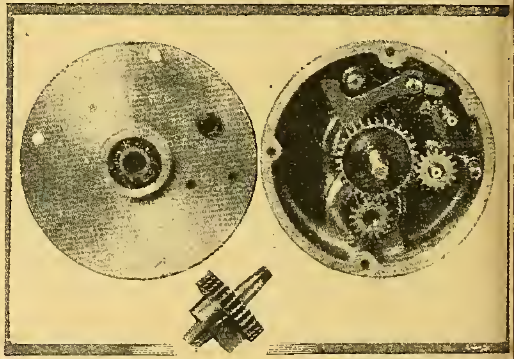

Fig. 21.—The Excelsior timing case and cover, showing the ball bearing in the latter for the half-time wheel.

Red Cross Motor Carnival at Christchurch, N.Z.

THE 1918 Red Cross motor carnival was held at Christchurch, New Zealand, on February 23rd, in aid of the local Red Cross funds. Large crowds attended, and the meeting was a success.

AUSTRALASIAN HEAVYWEIGHT CHAMPIONSHIP, FIFTEEN MILES.—For machines over 600 c.c.

S. Coleman (7 Indian) 1
H. R. Crawley (7 Harley-Davidson) 2
L. Maugham (7 Harley-Davidson) 3

These were the only starters. Time, 13m. 50s.—an Australasian record.

TEAM RELAY RACE, NORTH *v.* SOUTH ISLAND, FIFTEEN MILES.

South Island team:
Howarth (2¾ Douglas), Woodman (4¼ B.S.A.), and Crawley (7 Harley-Davidson) ... 1
North Island team:
Sweney (2¾ Douglas), Dawber (3½ Indian) and Coleman (7 Indian) 2

Time, 15m. 55⅕s.

OPEN HANDICAP, EIGHT MILES.—Ope to machines which could do 45 m.p. or better.

C. Bonnington (4¼ B.S.A.), 90s. start 1
A. Woodman (4¼ B.S.A.), 30s. start 2
H. R. Crawley (7 Harley-Davidson), 20s. start ... 3

Time, 8m. 55⅗s. There were five othe starters.

The track was an ordinary racecourse and not banked.

The Trend towards Mechanical Luxury.

Has the Evolution of the Motor Cycle progressed as it might have done?

IT is of more than passing interest to note how the perfecting of the motor cycle is following along lines similar to those which led to the evolution of the modern car.

The original single-cylinder De Dion car enjoyed a great share of popularity and gave rise to many other makes following the same principles. These in turn gave way before the two-cylinder class, which was again superseded by the four-cylinder type. Before the outbreak of war six and even eight-cylinder engines were being tried, and it is hard to say just how far matters would have progressed had "Willy" refrained from studying the map. It was very evident in those days, however, that car manufacture was branching into two distinct paths: the perfected four-cylinder, with all necessary refinements for the owner-driver, but designed with a view to reliability, long service, and easy manipulation, and the elaborate four or six-cylinder types embodying every luxury the mind could dictate, where comfort and splendour were paramount, mechanically and otherwise.

Transmission and Tyres.

In the field of transmission the chain was ousted by the cardan shaft drive, and three-speed gears were likewise supplanted by four ratio gear boxes. The necessary machinery was invented to enable mathematically correct gear wheels to be produced with marvellous precision, thus reducing noise and wear of the wheels when in operation. No car worthy of the name remained unequipped with either detachable wheels or removable rims, and earlier models were brought into line by means of the Stepney rim and similar fitments. To have to repair a puncture on the road was a very unfortunate *contretemps*, and a rightful occasion for much bemoaning of luck, whilst engine troubles appeared to have become as dead as the dodo, and tuning an art known only to and cultivated by certain prominent engineers or sporting young men who adorned Brooklands and other speed centres. *Apropos* of this, a car-driver friend of mine boasts of having driven a hundred thousand miles without even removing a tyre—his spare wheel and the talent of the local garage have solved his puncture worries—and only this summer he travelled over fifty miles with an annoying misfire on one cylinder, which proved to be caused by an oily sparking plug, and was cured by means of a rag and some petrol inside a few seconds.

"The Long, Long Trail."

There is a "long, long trail" to face before the motor cycle arrives at such a state of perfection that it can equal the car in reliability and convenience—and possibly some of us, who delight in tinkering with special jets and freak timing, fondly hope it never may—but the signs are not wanting that the hoe has been started on the furrow, and, however long and difficult the task may be, the evolution of the perfect machine will become an accomplished fact.

"Dreams and Realities."

One has only to recall the incessant outcry against the single-cylinder, the even more recent disparaging remarks anent the V twin, and the carefully worded advocation of the flat twin, to realise how uncertain the outlook really is. Belt drive is waning in popularity, and must eventually succumb before the universal adoption of the chain or shaft. Single lever automatic carburetters are quietly trying their strength before an open challenge is issued to the two-lever semi-automatic type, and even our tried and trusted friend, the magneto, seems destined to become mixed up in the fray to evolve later in a form known at present only to the gods.

Prejudice may hold back some of these improvements for a time, for motor cyclists as a class are more mechanically inclined than the car drivers of the corresponding pre-perfection period, and consequently may hold the opinion that improvement sometimes spells deterioration—therefore "well" is better left alone. Facts, however, are the best antidote for prejudice, and when some of the little bird whispers we have all heard at times materialise, and the spring frame, three or four-speed shaft-driven, four-cylinder motor cycle graces the road, one's nerves will vibrate with all the old-time enthusiasm, and prejudice will fly to the winds.

Waiting for the Perfect Motor Cycle.

The factories may resound with the hum of the shell lathes, but deep down in the brain of the man in charge may lie a little mental picture of the perfect motor cycle we are all pressing for, only waiting the lifting of the "control" and the release of the plant and materials for a chance to spring into being. It would be a bold man, however, who would attempt at the present moment to dictate the specifications of the Triumph, Sunbeam, Norton, or A.J.S.—to name only a few—for the third year following the signing of peace, but the most simple-minded amongst us can safely say it will not be the pre-war model.

FRANCIS E. SCHOFIELD.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

,, 29th	... ...	9.31 ,,

Change of Address.

The Petroleum Executive has removed from 8, Northumberland Avenue, to 12, Berkeley Street, W.1—to be nearer the Controller at No. 19, perhaps.

The Late Mr. James Gordon Bennett.

Mr. James Gordon Bennett, the American newspaper millionaire, whose name is associated with the classic motor race for the "Gordon Bennett cup," died in France on the 13th inst. Mr. Bennett was in his seventy-seventh year, and with his death passes one of the strongest of characters and a unique sportsman. He encouraged motor racing by the institution of the Gordon Bennett cup, he introduced polo into America, revived coaching in France, and owned a yacht, which was aptly named *Lysistrata*. This magnificently appointed vessel violated all the rules of yacht design. It resembled a tramp steamer more than a luxurious pleasure vessel, and was perhaps the key for the world at large to judge his character. Mr. Bennett owned, among other papers, the *New York Herald*, and it was he who sent Mr. H. M. Stanley to Central Africa in search of Livingstone. In 1914 he married the Baroness George de Reuter, widow of the second son of the founder of Reuter's News Agency.

Petrol Licences Issued.

The number of licences issued by the Petrol Control Department to each class of user of motor spirit up to 4th May is shown in the following table:

	3rd issue.	4th issue.	5th issue.
Private cars	70,452	59,620	13,001
Private cycles	34,462	29,152	16,005
Doctors' cars	10,698	11,701	
Hackney vehicles ..	16,351	15,291	
Commercial vehicles	38,880	31,772	
Industrial processes	60,104	57,438	
	230,947	207,974	29,006

We published the figures for the first four issues in *The Motor Cycle* of March 21st. The figures of the third and fourth issues above are different from those previously published, but no explanation of the discrepancy is given in the *Board of Trade Journal*, from which we take the information.

Progress of Licence Issues.

The first issue of licences to "private cycles" was 95,098; the last is 16,005!

Special Features.

VALVE MECHANISM.

A NEW 500 c.c. TWO-STROKE.

SIDECAR DESIGN.

The Holiday.

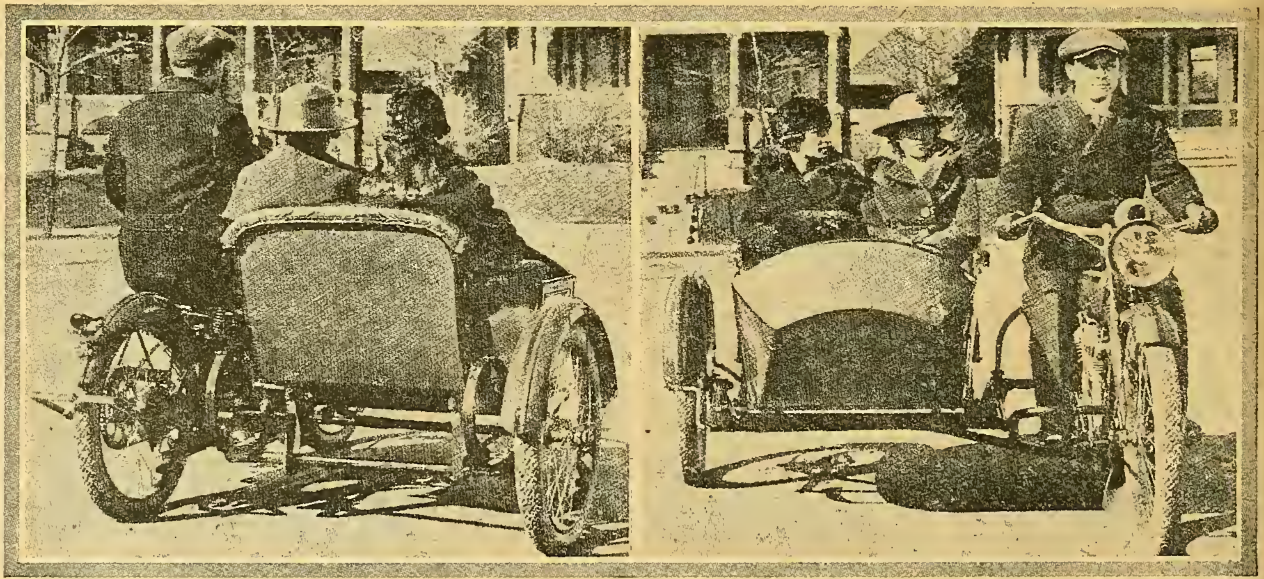
What a Whitsun! How many of ou readers must have made this comment a they looked longingly at the shinin highway? Hardly a motor cycle was t be seen, however, and a member of ou staff who lives near a country inn that i ordinary times is the resort of literall thousands of motorists on a Bank Holida saw one motor cycle and two cars.

The Pedal Cycle.

No one can deny that the war ha been a good thing for the push cycle Monday was almost like a pre-moto Bank Holiday. Thousands of pus cycles were on the roads.

Cruelty to Animals.

Why does not some daily that spend much time and money in conducting a anti-motoring campaign devote an occasional column to the cruel overloading o horses that goes on at holiday times? I is a common sight to see one horse tugging a load of ten passengers some twent miles or more.



Two views of the new two-seater Harley-Davidson sidecar. Such practice is not new by any means in England, though it has not "caught on" to much extent. Just previous to the war, however, it seemed as though the idea might become more popular, as several sidecars of this type were seen about.

oad Transport.

Under the new Defence of the Realm egulation the Board of Trade is to re-rganise road transport, and will be able o restrict the use of horses and vehicles, ake possession of them, or require them o be placed at the disposal of any speci-ed person.

New Two-stroke.

A vertical two-stroke with two cylin-ers having a common combustion space ay be tried as a lightweight engine fter the war. In this design, the pistons ork in unison, and the transfer and xhaust ports are in different cylinders, he new gas having to travel up the one ylinder and down the other before it an escape *viâ* the exhaust port. An ngine on these lines is fitted in the well-nown Valveless car, which is, by far, the ost successful two-stroke car that has een placed on the market.

he Auto-wheel in France.

An American, who is a member of the ed Cross, uses a Smith motor wheel, hich is the American Auto-wheel, in rance in the execution of his duty. hortly after the restriction forbidding he use of private motor vehicles in that ountry he had occasion to make a long ourney, and not having any authorisation o use his motor at the time decided to risk t. On one occasion he was stopped by a rench soldier, who said to him: "I must old up all automobiles, but I have no rders to catch insects; besides, I have o net, anyway." He has found the ttachment to be of extreme value in iew of the scarcity of fuel in France uring the last few months.

Motor Cycle Recruits Wanted.

The 1st Battalion County of London Volunteer Regt. has vacancies for recruits owning motor cycles and sidecars. Particulars can be obtained from the Recruiting Officer, 231, Oxford Street, London, W.1, between the hours of noon and 8 p.m. The headquarters of the regiment are the Imperial College Union, Albert Hall, South Kensington, London, W.8. Hours of attendance are Mondays and Wednesdays, 7 to 9 p.m.

A Malicious Prosecution.

We recently received a letter from a young reader, a schoolboy in the West Country, who, during his holidays hired a motor cycle and sidecar for the purpose of attending a sale and calling upon various of his father's clients in the surrounding district. His father is in the furniture business, and, owing to shortage of staff, his mother is at present acting as buyer, and she was taken by him as passenger. While in the pursuance of business he was stopped by a policeman, who, having seen the usual licences, pointed out that there was a station two and a half miles distant from the place of call, and although he agreed that the train service was most awkward, he, nevertheless, issued a summons for the illegal use of motor spirit.

Acting on our advice, the young defendant immediately took steps to become a member of the Auto Cycle Union, and by placing the facts of the case before them he was able to get their legal department to get him represented by a solicitor, free of charge, with the satisfactory result that when the case came up to be heard it was dismissed.

The Latest Idea in Pistons.

A piston in which the skirt has an expanding ring was mentioned to us recently. It is claimed that the conventional piston ring is eliminated.

The "Win-the-war" Spirit.

"See that a win-the-war spirit gets into your business letters" is the slogan of a movement just launched by the Department of Commerce in America.

A Long Stroke Two-stroke.

A twin-cylinder two-stroke with cylinders 60 × 100 mm. bore and stroke respectively, and embodying a sleeve valve, is in its experimental stage. It is intended for sidecar work.

Motor Cycle Racing.

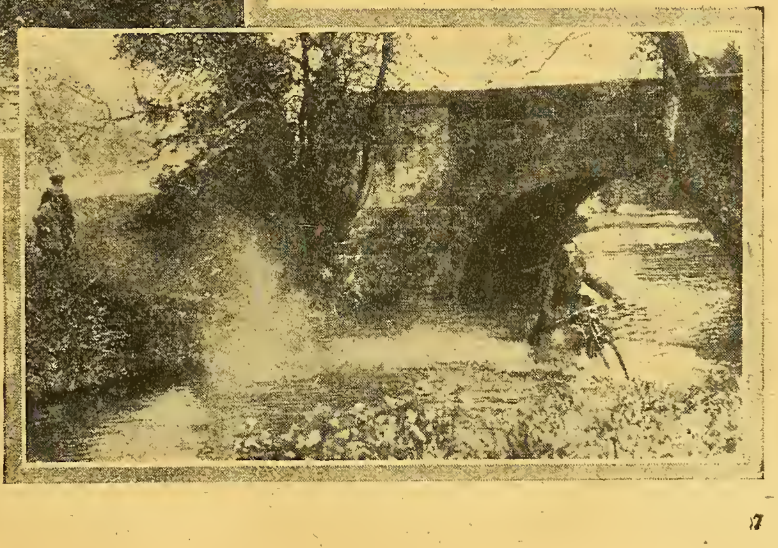
It is strange that a nation of sportsmen such as the British has not given greater attention to motor cycle racing as a sport. In pre-war days tens of thousands of men visited football matches every Saturday. Would not motor cycle track races prove an attraction and a financial success?

The 4 h.p. and Sidecar.

It was interesting to hear the opinions of a few men very closely connected with the motor cycle industry on the question of their mount after the war. Although admirers of the four-cylinder shaft-drive, three out of the four were unanimous in their choice of the 4 h.p. single-cylinder. The other man's vote was for a powerful V type twin. It would seem that, in spite of the attention being given to big and powerful sidecar outfits, the 3½-4 h.p. single-cylinder will not easily be displaced.

"Storing" Motor Cycles.

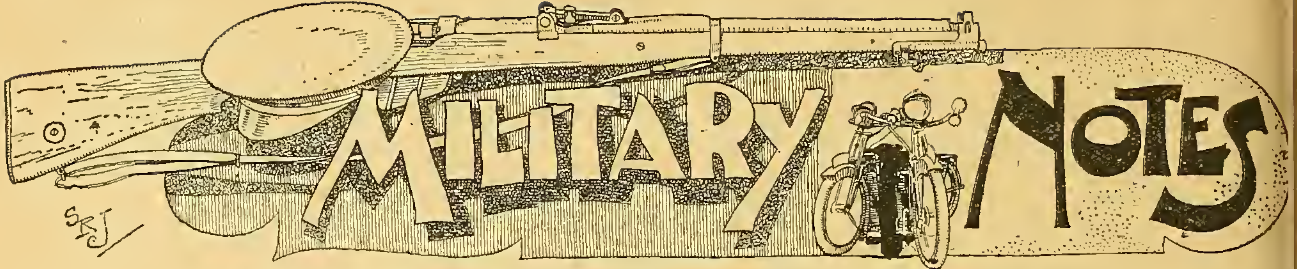
To those men who are in a position to look after their motor cycles, we would give a note of warning. Quite recently we passed through a private garage, in which there were stored at least a dozen motor cycles. The state of the machines generally was appalling, only three or four being in a clean condition; the rest were covered with mud and oil, and in a bad condition generally. One or two of these machines were owned by men serving Overseas, but in the other cases it was simply carelessness.



A Triumph tester on a stunt. It is not an ordinary negotiation of a watersplash, but a demonstration of the waterproof qualities of the M-L magneto, which stood the test without a misfire.

The Double-seated Sidecar.

We hear from America that the Harley-Davidson factory is now turning out a special sidecar provided with a body carrying passengers side by side. The new double sidecar is to be made to order only. The sidecar seat is 30in. wide inside, so there should be enough room for two people.



Addressing Letters. Four-cylinder Motor Cycles. Promotions.

LETTERS AND PARCELS FOR THE TROOPS.

TO avoid confusion by the use of initial letters only to represent the title of the force with which the addressee is serving, the public are strongly advised to write the titles of the expeditionary forces in full when despatching letters and parcels.

* * *

DISCHARGED SOLDIER WANTED AS SERGEANT-MAJOR.

THE strength of the Central Group of the Middlesex Motor Volunteers is still minus a sergeant-major. Such a position requires a man who, besides being fully experienced in all that pertains to soldiering, possesses a good general knowledge of motor vehicles. If any of our readers know of a discharged soldier possessing these qualifications, will they ask him to communicate with the C.O., 19, Queen's Parade, Muswell Hill, London, N.W.I?

* * *

LEAVE AND PETROL.

WE have received an interesting letter from Dvr. Reginald Samson, who before the war was for some time managing director of Reg. Samson, Ltd., Islington Row, Birmingham, and well known in motor cycling circles in the Midlands as a competition rider.

He makes some very caustic remarks on the Petrol Control Committee. He says: "I have been home in England for my first leave in just over three years, and, although the owner of a motor cycle, and having some petrol at my command, I could not get the necessary permit from the Committee. The time being short, I gave up the matter. I called on the Ministry of Munitions in Birmingham, but they could not do anything.

"The food question did not affect me much; I got plenty.

"Generally speaking, I am not favourably impressed with the England of to-day, and am glad to be back again in the Balkans. I told my friends to expect me back in England in 1921. I expect I shall not be far out when the time comes, and then probably only on leave.

"The last eighteen months or so I have been driving a heavy lorry in Salonica, but have now moved up on the Serbian front. It might be of interest to you to know that my present O.C. is Capt. Chater-Lea. I am now miles away from civilisation, and the country is most hilly and desolate. It is a land of mountains, rocks, and ravines. The motor cyclist is more or less a *rara avis*, as, once the telephone wire is down, there is not much for him to do; but light Ford lorries are as abundant as mosquitoes."

WITH THE INLAND WATER TRANSPORT. A CHEERFUL NOTE.

SAPPER THOMPSON, I.W.T., R.E., writing from Mesopotamia, says: "It is just grand to be able to get the 'Blue 'Un' out here fairly regularly. We are rather away from the old game now, inasmuch as we are floating about on the river instead of the land. It will be a case of port your helm, or hard to starboard for us in future instead of the old road terms. It is surprising how we the little Douglas stands the gruelling gets out here and in *such* heat. Th roads here put whiskers on a fellow; suc a lot of second gear work necessary. Nev mind; when all is over we will be on more in our element with a decent roa on which to have a little 'blind.' I a sorry to hear what a trouble it is to g petrol at home. Here we live almost o the top of an oilfield, so we have it wit our meals so to speak.

Sapper Thompson, of the Inland Water Transport in Mesopotámia, aboard the launch "Amara."

Sappers Thompson and Cummings in Arab dress. In the background on the right is a mud church. Thompson tersely describes it as "some" church.

"Rather pleased to see the intere taken in four-cylinder motor bicycles i your last few issues. Undoubtedly th is *the* touring mount. I am for Henderson after the war, *but not* wit the twist grip. I hope I have offende no one by running the American control down.

"Good luck to the best all-round pape for the motor cyclist. I do not mind you attitude *against* German goods one bit Oh! that other poor fellow. He *will* mis his paper, won't he? But he will buy a odd copy or two when no one is looking

"Keep smiling in dear, old Blighty We will soon *all* be back, and then——

* * *

EXCHANGE OF PRISONERS.

WE understand that the Governmen is considering what steps can b taken to effect a wider exchange o British and German prisoners. Negotiations have not yet been opened, and it i not known whether Germany woul agree to any proposals.

* * *

A MOMENTOUS DATE.

A REPORT from The Hague says tha the date fixed by the Germans fo the occupation of Calais was unti recently Whit-Sunday. We have n information as to whether another dat has yet been fixed.

* * *

MOTOR CYCLISTS PROMOTED

WE notice in a recent *Gazette* tha Temporary Capt. J. Chater-Lea jun., A.S.C., has been promoted t the rank of Temporary Major, and tha Temporary Capt. S. W. Carty, M.C. A.S.C., has also been promoted to th rank of Temporary Major.

J. Chater-Lea, of course, is wel known to our readers as the son of Mr Chater-Lea, the manufacturer of moto cycles and sidecars, motor cycle component parts, engines, and cycle cars Chater-Lea, jun., took part in numerou important competitions.

S. W. Carty is best known to ou readers as secretary of the Mersey Moto Club and a member of the A.C.U committee.

THE MOTOR CYCLE

AVIATION SECTION

The enormous importance of the Air Service needs no emphasis; it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National Service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouragement of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

Bombs.

In April, British airmen on the estern Front dropped 23,900 bombs on e Huns.

◇

An American Airman's "Bag."

An American airman named Beyer has ougbt down on the Western Front ven Hun planes, two of them in e day.

◇

First Government Mail.

Gustave Hamel carried the first bag of O. letters by aeroplane from Hendon to indsor in 1911. He covered the nine-en miles in thirteen minutes.

◇

Larger Gothas.

A recent official *communiqué* says that a large enemy aeroplane" has been ought down. It has been known for me time that the Germans have lately oduced some big machines, including a tha, to carry a considerably larger load an the ordinary Gotha.

It has four 260 h.p. engines, with two opellers in front and two behind. Its dth is about 130ft., and it has a crew five. The ordinary Gotha has two 0 h.p. engines, with two propellers, a dth of about 80ft., and a crew of three. *Daily Mail.*

◇

Australian "Sang Froid."

Conspicuous bravery was displayed by Queensland officer on the Western Front st week. At dusk, a British airman as forced to descend after a fight. The achine turned over, and the pilot was able to unstrap himself. The Germans ened fire and splinters flew from the eckage, and the airman, freeing him-lf, lay down for cover. The Queens-nd officer led a stretcher party in full ew of the Germans across several ndred yards, and brought in the air-an. This bravery apparently impressed e enemy, who refrained from firing.

Aerial Posts.

An aeroplane mail service was commenced last week between Washington and New York with a stop at Philadelphia. The distance between the two cities is about 220 miles. Two airmen started simultaneously from both these cities on planes capable of carrying 600 lb. of mails.

It is not proposed to inaugurate an aerial postal service during the war between Stavanger and Aberdeen.

◇

AIRMEN MOTOR CYCLISTS

Lt. Alan Jerrard, R.A.F., who before the war was a keen motor cyclist, has been awarded the Victoria Cross. When on an offensive patrol he attacked five enemy aeroplanes, and shot one down in flames. Later he engaged single-handed nineteen Hun machines, destroying one. Lt. Jerrard had greatly distinguished himself on five previous occasions. A recent report states that he is now a prisoner of war in Austria.

Lt. Alan Jerrard, V.C., R.A.F.

Gift to Royal Air Force.

Lt.-Col. Sir A. E. Bingham, Bart., has presented an aeroplane to the R.A.F.

◇

A Single-handed Attack.

A patrolling seaplane under the command of Pilot Capt. Patterson attacked a Zeppelin over the North Sea for thirty-five minutes last week, and forced her to retreat to the German coast.

◇

A Vivid Pen Picture.

That the French pilot can lend as much *entrain* to his pen as he can to his control lever will be seen by the following description, taken from *La Guerre Aerienne*:

"The four of us mount to 3,000 metres. There, oh happiness, we find several Boches. Doubtless feeling a call to safer places, when they see us they flee. This was neither kind nor polite on their part, so we give chase to recall them to their manners, and, thanks to the speed of our avions, are able to overtake and turn them.

"I attacked a Fokker, which fled like a rabbit, but my Baby Nieuport had the wings of him. Not wishing to prolong the pleasure unduly, I drew up to within several metres, and spat the whole drum at him. A second or two later he was in flames, finished! My motor chooses this instant to fail, I lose height, and another Boche comes surging at me. I let myself slip, keeping in an impeccable straight line so as not to deviate a metre uselessly, for fear of falling on the wrong side of the lines. A moment later—why? I do not know, but what joy!—the Hun abandons the chase (perhaps he sights one of my companions), and I pass the lines lower than three hundred metres. A new fusillade, but without consequences, and I land at last. Ouf! My avion had received five bullets; as to me, nothing worse than fear, but *what* a fear!"

STUNT FLYING

PART III. By "Torque."

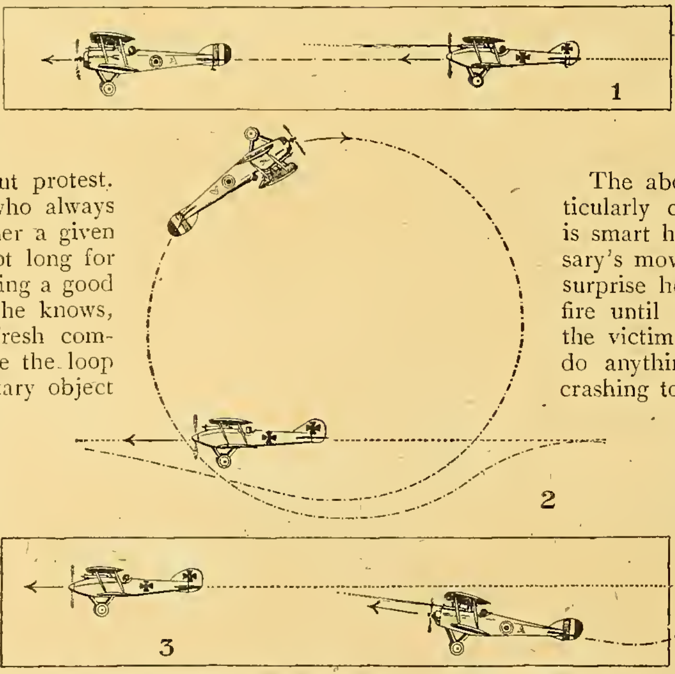
In the following article our contributor describes the "loop" and shows its tactical value in aerial warfare.

In the early days of the war, when stunt-flying was in its infancy, this article might have brought Dora hotfoot on my trail; to-day it is devoid of interest to any Service pilot. I should preface it with the explanation that I have isolated a single stunt—the "loop"—in order to give some idea to readers ignorant of aviation that stunts are of distinct offensive and defensive value in aerial fighting. In air fights, as in all warfare, the element of *surprise* is vital in tactics. If a foe of average intelligence can guess what you are going to do, and has an adequate counterstroke at his command, you had better keep quiet or resign yourself to die without protest. So in stunting, the pilot who always adopts the same stunt under a given set of circumstances, is not long for this world. In actual fighting a good pilot employs every stunt he knows, and weaves it into ever fresh combinations. I merely isolate the loop for the sake of an elementary object lesson.

Fig. 1 shows a Boche machine on the tail of a British machine. The British pilot is helpless for the moment, and will be dead in ten seconds unless he takes rapid counter measures. He has been taken by surprise. Perhaps the Boche has dived down out of a cloud. Perhaps the Britisher was dazzled by the sun, or watching anothe machine miles away, or had a splodge of lubricating oil on his glasses, or was trying to tighten an oi joint. The exact cause does not matter. We wil pretend he did not know there was a Hun scou within miles, and suddenly he has heard the tack tack of a machine gun punctuating the sustained roar of his engine, and seen a white splinter fly from some adjacent woodwork. Fritz is shooting at him and he cannot shoot back, for his own guns are rigidly fixed to the fuselage before him, and will only fire forwards. We must further suppose that Fritz is a fool, and is not expecting a loop on the part of the Britisher; actually, Fritz is no fool: he is watching like a cat, and out of his bag of tricks he will produce some dangerous counter move, whatever the British machine may do. But we will suppose that Fritz is a fool, and holds straight on.

An Actual Aerial Combat.

Fig. 2 indicates that the Britisher promptly loops the loop, and that Fritz keeps straight on. Fig. 3 shows their respective positions a few seconds later. Fritz is now in front; Fritz's guns are blanketed, because they too only fire forward; the gap between the two machines has widened a little, because the Britisher lost a little distance while he was chasing his tail; but at any rate, he is now top dog. He can use his guns if his sights line up at any moment; he occupies for the moment the commanding position.



1. A British aeroplane chased by a Hun. 2. The chased loops the loop, leaving the chaser to continue his horizontal flight. 3. The chased now becomes the chaser and can use his gun.

The above is not, of course, particularly convincing. If the Boche is smart he can follow all his adversary's movements, and in effecting a surprise he would probably hold his fire until his aim was perfect, and the victim would have no chance to do anything, because he would be crashing to earth miles below. Still, the conditions shown have actually occurred. For example, if the attacking airman has swooped down in a long dive, with his engine fully on, he cannot pull out of this dive instantaneously without subjecting his machine to a stress of many more tons than it will bear. The dive must continue while

Stunt Flying.—

the victim loops. When the loop is complete the distance between the two machines will have widened considerably, as Fritz on the dive is always very fast, and a loop is comparatively slow.

Fig. 3 would then show the machines widely separated with the Britisher on top: and an imaginable fig. 4 would depend on whether both men were equally full of fight. For example, Hun machines are generally slow climbers compared to ours, and if Fritz found himself underdog over his own lines, and without any support at hand, he would probably break off the fight: our man might hesitate to go down, with the chance of being coaxed over a nest of Archies: and the fight would be over for the time. Now that formation fighting is the rule rather than the exception, actual aerial battles practically defy analysis: and the above can only be regarded as rather an artificial object lesson.

Strategy in the Air.

The loop, however, is still a good sound stunt, because it may or may not be completed. It begins with a very steep climb: and so do several other stunts. Immelmann slaughtered many of his victims by inventing a special type of turn (described in "Flying Facts and Theories," Control III., May 9th), which began like a loop. As he climbed, creating the illusion that he was going to loop, and tempting his prey to fancy he knew Immelmann's probable position ten seconds later, the Hun would wrench his machine round just before his tail pointed vertically downward and come back at his enemy. Thus he gained height, instead of losing it: and when the manœuvre was complete, his machine and its guns pointed in exactly the opposite of that direction which a loop would have given them. This was very disconcerting, as long as it was new. In like fashion, a pilot may dip his nose slightly, and begin the fierce upward rush which looks like ending either in a loop or an Immelmann turn: but it may develop into something quite different. Instead of coming back at you in an Immelmann turn, he continues a spiral climb, and keeps above you, ready for a second dive when a chance occurs. Or, if he wishes to break off a fight, he may bank over after executing the first third of the loop, and stand his machine with a wing tip pointing vertically downwards. If he holds it long enough on this course, the machine must stall, because its planes are not designed to "lift" in this attitude. In a very few moments he will have wing-slid a thousand feet or so, and unless you have avoided the three or four false deductions which were open to you when he pretended he was going to loop, he is now far beneath you, and your guns are probably pointing in quite a different direction.

Where the Danger lies.

It is the combination of stunts which is dangerous either in attack or defence: and obviously the move which looks like one thing, or one of two things, or one of three things, and develops into something utterly different within ten seconds, supplies that element of surprise which is so vital to successful tactics.

The time factor deserves underlining. Broadly speaking, British scouts possess a better "performance" than German scouts. They can climb faster, because they are aerodynamically more efficient, and their engines are lighter in proportion to h.p. If you particularly wish to "crash" a German machine, and know you can outclimb it, it may sometimes pay to let him snatch the upper position. Provided he is given no opportunity to reach your blind spot, and shoot you down, you cut off his retreat to a certain extent by being below him. On the other hand, his machine is heavier than yours, in all probability, and will therefore dive faster. Consequently, you must be careful about letting him get altitude: for he can then dive, to attack or escape, as he may prefer, and he can outpace you on the dive. Thus you must decide whether your superiority on the climb is, at the moment, of more value than his on the dive, and having decided you must act—quickly.

* * *

WITH THE AMERICAN EXPEDITIONARY FORCE IN FRANCE.

An aviation field where Americans are schooled in combat flying before going to the fighting line.

THE EXPERIENCES OF A "HUN."

I.—Impressions of an Observer on controlling an Aeroplane for the First Time.

By "PITOT."

THE majority of pilots are trained as such from the very beginning, but nevertheless there is always a percentage of observers who have served (and survived !) their time in France, and come home for the purpose of changing their single wing for the double one.

I am lucky enough to be numbered among this happy band, and recently joined an elementary squadron, where, with many others, I mastered the intricacies of the jovial Rumpety.

The Rumpety is, indeed, a fearful and wonderful machine. No one seems to know the reason for its name, though some suggest it is derived from the "Rumpety-rumpety rump" of its song in the air. The nickname is, none the less, expressive.

A walk round the hangars on reporting to my new squadron proved a most edifying and surprising tour.

Instead of the sleek, speedy-looking machines which had hitherto graced my vision, huge and unwieldy looking monsters smote my outraged retinæ. There was no form or beauty about these leviathans as they crouched there in their hangars on squatty little under-carriages, graced with four "super-scooter" wheels. Each seemed to leer in a superior manner, as much as to infer, "Wait till I get you in *my* nacelle."

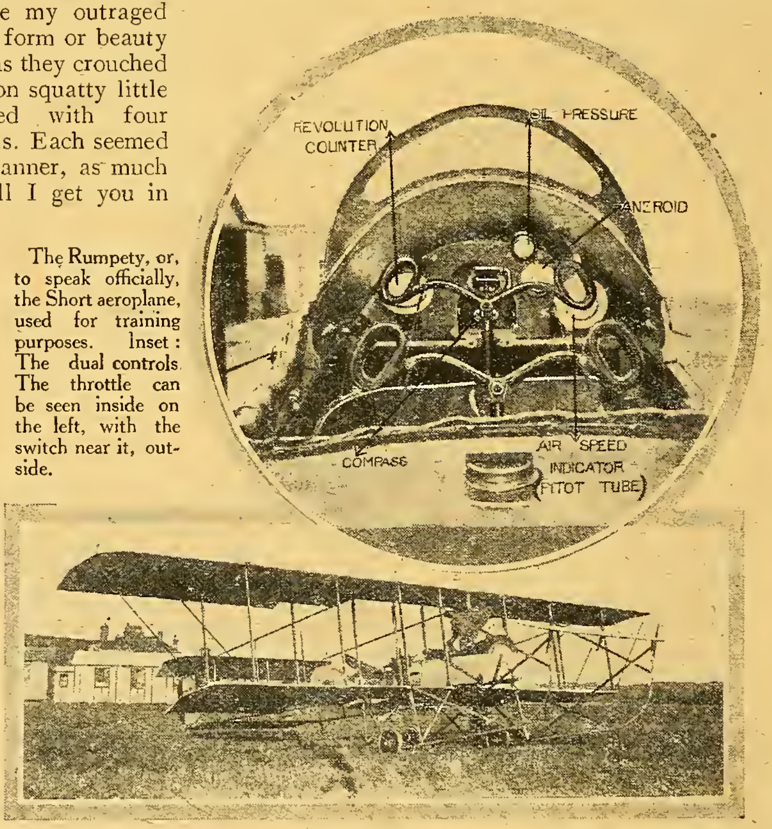
Their span was enormous, and from between the upper and lower wings projected a snout, in profile much like a rhino's head, with a totally inadequate-looking engine and propeller adorning its rear extremity.

An intricate ascent through, over, and around this very greasy jungle, rewarded the inquisitive one with a view of the intestines of the machine; the seats for instructor and pupil and the controls.

What controls!

Rearing its head in place of the usual neat "joy-stick" was a lever with two outward sprouting growths from its head, culminating in grips uncommonly like scissor handles, the whole thing strangely reminiscent of a pair of spectacles balanced on the end of a walking stick.

Moving the whole concern forwards or backwards makes the machine dive or climb.



The Rumpety, or, to speak officially, the Short aeroplane, used for training purposes. Inset: The dual controls. The throttle can be seen inside on the left, with the switch near it, outside.

Twisting the handles up and down makes it "bank" either way. Directional control of the beast is assured by two pedals strongly resembling those of a harmonium. These move the rudders—for this weird contraption possesses two!

A day or so later the clouds were chased away by a brisk breeze and flying began. The mastodons were hauled out, their engines primed and started, forthwith they lumbered majestically along the ground, and lo! they rose into the air and flew.

That is to say, if the cavortings of such colossi can be likened unto the airy grace of birds, they flew!

At length I was seated in the back seat with pilot in front and engine behind, surmounting my head a so-called "crash-hat" like unto an inverted and abbreviated drain-pipe, and around my corpulent middle a belt—"just in case," you know!

A few preparations, "contact," and the beast belched forth its roar just behind my ear. To one unaccustomed to "pushers" the noise was unpleasing.

The man at the wheel being satisfied with the "revs.," the machine began to move along the ground, so as to get into wind before taking off. One final wave of the hand, a roar from the exhaust merging into an ear-splitting crackle, a rush over the grass, and the flight was begun—the strangest I ever had.

It was "bumpy" and had begun to rain again. Round and round the aerodrome wallowed and snorted the beast at a mere "00" feet!

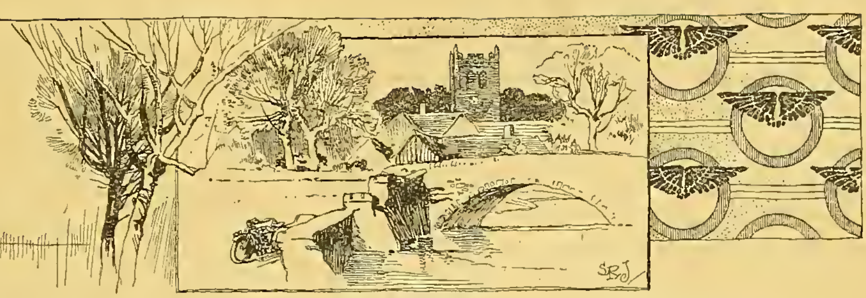
Suddenly the engine ceased its cacophony of clamour, and began to spit and splutter in sullen muffled rage. The machine set its nose for the green fields beneath and glided down, "bumping" as it glode. It flattened out, skimmed along, and landed itself gently upon the aerodrome.

With feelings of relief, not unmingled with respect, I clambered down to *terra firma.*

The machine merely leered at me.

(To be concluded.)

SIDECAR DESIGN.



Should the Sidecar be Convertible and Detachable? Suggestions for Reducing its Cost of Production if made as a Self-contained Vehicle.

As one who is interested, largely from a manufacturing viewpoint, in the future of the sidecar combination, I should like to add a few remarks to your article of May 2nd. The article in question deals with the type of engine that will be most popular in the, let us hope, near future. There are good arguments for the single, the twin, and the four-cylinder, but what I think far more important is the design of the combination as a whole.

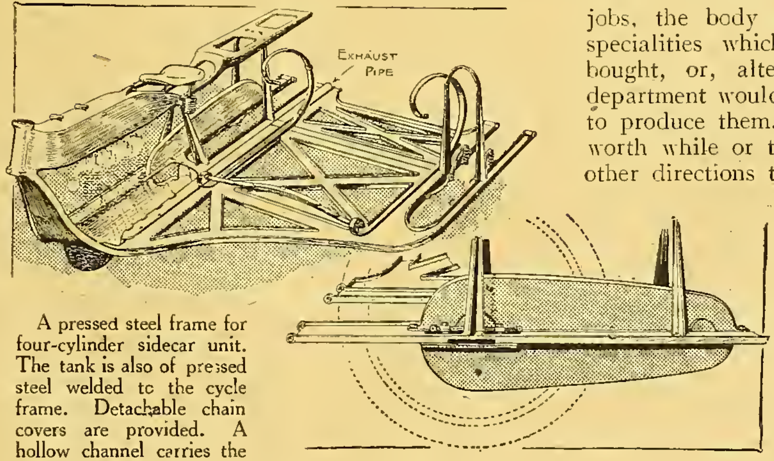
How the Sidecar Combination was Evolved.

The sidecar combination, whether single or multi-cylinder engine be employed, is an evolution. Originally introduced as an attachment, the sidecar has become in reality a fixture. No sidecar owner contemplates detaching a sidecar for convenience of storage: it is too irksome and sometimes too lengthy an operation, and when this method is adopted the sidecar is seldom in line with the cycle after one or two attachings and detachings.

I know many sidecar owners who garage three-quarters of a mile and a mile away from their homes in preference to taking off the sidecar and replacing it in the street. To all intents and purposes, therefore, the storage question is approximately the same as that of a small car.

Manufacturers recognise this, and possibly it explains the reason why so many motor cycle makers laid themselves out to design and produce sample cycle cars when the little four-wheeler was revived some years ago. They recognised that they had sold a great number of sidecars, and thought probably that the cycle car would be a serious rival, quite 50% of their sales of motor bicycles being due to the facility of attaching a passenger-carrying machine to the solo vehicle.

Time has proved that they have so far had no reason to fear competition from cycle cars. This brings me to my line of thought in connection with sidecar combinations, and I am going to ask a somewhat hoary question: Why should the sidecar be detachable? Afterwards I will explain the reasons why it has been so made up to now, and make a few suggestions for making it a self-contained vehicle in future.



A pressed steel frame for four-cylinder sidecar unit. The tank is also of pressed steel welded to the cycle frame. Detachable chain covers are provided. A hollow channel carries the exhaust to the back.

Motor Cycle Makers and the Sidecar.

We will begin with the question, Why should the sidecar be detachable? It has been so made because its introduction and manufacture were and are in the hands of specialist firms. It received its first encouragement, from a manufacturing standpoint, from firms who, previously to the sidecar, made trailers and forecarriages. It came to them originally as an adjunct to their business, something to be encouraged and exploited for their benefit as well as of advantage to motor cyclists, their wives, sisters, and sweethearts.

The motor cycle manufacturers left it severely alone, as they do almost to this day. It was not suitable for their machinery, the profits were inconsiderable, the assembling and manufacture generally occupied a lot of valuable space, and only the wheel and frame were cycle makers' jobs, the body and upholstery being specialities which would have to be bought, or, alternatively, a separate department would have to be organised to produce them. Finally, it was not worth while or they were too busy in other directions to bother with it.

The next reason why it remains an attachment is because motor bicycles are standardised, so far as individual manufacturers are concerned. It is cheaper to produce motor bicycles in quantities in an organised factory and equip them afterwards with a sidecar than it is to redesign a machine completely.

Directors and works managers dislike alterations in design. Once started on production they can go on reducing cost year by year, provided there is no fundamental alteration. Introduce a new thing altogether and the production organisation is upset.

Sidecar Design.—

This largely explains the success of the unmechanical makeshift which, despite its drawbacks, is the most economical, fastest for the power employed, and most enjoyable form of passenger motor cycle extant.

I have had a lengthy experience of cycling, motor cycling and motoring, and if the fairies were to come to me and present me with a first-class car, heaps of petrol, and free garage, I should still occasionally yearn for a good sidecar on which to go for a ride, in lieu of sitting at the wheel of a car with only the accelerator pedal to push.

This interlude is to explain that I have no quarrel with this type of motor, even when compared with the best car that money can buy.

Outline of the Suggested Three-wheeler.

Having set forth some of the reasons why, in my opinion, the sidecar has remained an attachment so long, I will now give an outline of what might be done with this type of machine to render it more of a self-contained vehicle and less of a convertible article. By adopting my suggestion in some form or other, the production of sidecar combinations would be reduced in cost and strengthened at their weakest point, viz., the method of attachment.

Reference to the sketches accompanying this article will show that the broad suggestion consists of a pressed steel frame built up of two or more parts, which would be riveted together. The part on which would be assembled the engine, gear box, tanks, etc., consists of one steel pressing, which would extend from the front to the rear of the bicycle. Riveted to this pressing, which, for want of a better name, I will term the cycle frame, would be another pressed steel section of triangular shape, on which would be placed the sidecar body, C springs, and the wheel, which could be either of the rigid or sprung variety.

There is no doubt that this design would be cheap to make, once the necessary tools were made for the pressings. These would be costly, and it would be impossible to make pressed steel sections of the shape required with one or two sets of dies. Several sets would be required. However, to make an experimental model it would be best to make the shapes wanted from ordinary sheet steel, cut, formed, and riveted at various points.

The ball steering head to carry the front fork could be welded to the frame by the electrical or oxy-acetylene process; the reinforcing flanges, thrown up at the edges for securing the necessary strength to a flat section, could be riveted or welded on; and the portions which required cutting away for the attachment of the engine, gear box, rear wheel, etc., would, in the case of an experimental model, have to be chiselled out by hand and filed up to shape.

When completed, if a trial machine proved satisfactory and the necessary dies were made to produce in quantity, imagine the saving in the cost of frame building, brazing and filing-up innumerable joints, and machining a number of intricately-shaped lugs. The bicycle part of the pressing could combine, in the process of shaping one half of a chain cover, a sort of well in which the lower half of the transmission would be made to run; if such a well presented difficulties in production for the steel presswork makers, it could be pressed separately and riveted on. The top half could also be pressed in the same way and fitted over the trough or bottom half, thus forming a completely enclosed case for the chain transmission.

The pressed frame of the bicycle portion would form an efficient mudguard and under-pan or shield dispensing with the usual mudguard and stays. The same pressing would form a firm support for the rider's feet; no separate footrests would be required. Attachments for such points as speed gear levers, oi pipes, stands, silencer pipes, magneto, etc., would be simplified, for the reason that a pressed stee section presents facilities in the way of ready attachment of such parts by riveting or bolting, whereas a tubular steel frame must have lugs designed to be built into the frame, or clips for the securing of such parts. A tubular steel frame is most unsuitable for the attachment of anything except by brazing, and every brazed joint weakens the frame; or, to express it another way, the gauge of tubing employed requires to be very much thicker to withstand so many brazings.

The Disadvantages are Two.

What are the disadvantages of such a design? Reduced to practical limits they are only two:

(1.) The sidecar is not detachable, and when the machine changes hands the sidecar must go with it.

(2.) In some cases it is easier to get at the transmission of a motor bicycle with the sidecar removed.

The first is relatively unimportant; sidecar combinations usually change hands in a complete state.

For the second, I have owned innumerable sidecar combinations, and have only once had to detach the sidecar to facilitate adjustment of the transmission, and then only for convenience sake; I could have got at all the parts without removing the sidecar. Does a car owner take off the body to get at the universal joints? Of course not; he either uses a pit or crawls underneath the chassis—either is more irksome than access to the transmission of a sidecar with the body *in situ*.

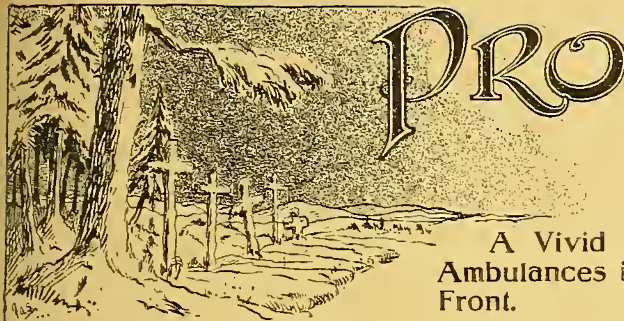
The motor bicycle frame is an evolution of the pedal bicycle; and a marvellous piece of work is the latter: I would not disparage it. It combines lightness with great strength, but when it comes to sidecar combinations I regard the pressed steel idea as cheaper, quite as strong, better for assembly of parts, greater rapidity of production, and a more mechanical and stronger method of combining the two frames without tubular stays and joints.

So far I have not touched on the question of seating. When a three-wheeler is made as a self-contained vehicle it is not surprising to hear suggestions for side-by-side seats. It is a natural desire, but as it entails springing the whole machine to provide a reasonable degree of comfort, I propose to retain the usual saddle seat and separately sprung body and wheel.

The sidecar combination must be cheaply produced, and one cannot introduce springing and hosts of complications without increasing expense, and then the purchaser turns his attention to a small car.

I suggest at least a 3in. tyre and 28in. wheels, having tried both 26in. and 28in., and found the 28in. more comfortable and better in many ways than 26in.

I now leave the idea to the tender mercies of my critics, who, I quite expect, will have some weighty arguments to bring against it. MECHANICUS.



PRO PATRIA.

A Vivid Description of Work with the Sidecar Ambulances in the Mountainous Part of the Western Front.

"IT is not cold to-night, Monsieur. You rest *couché* in the sidecar!"

The *Maréchal des Logis* is an optimist.

"*Oui, mon vieux.* And you?"

"I ascend to the dressing station. I will tell you in good time before the *blessés* arrive."

We watch his stooping figure till it disappears along the precipitous pathway, swallowed up among the shadow of the firs; then we turn to our sidecars and make all comfortable. The bitter frost has relented, and there is a touch of spring in the air. There is to be a *coup de main* to-night, somewhere along the line within a mile of where the sidecars are now stationed, and we are here in preparation to carry away the wounded. It is our third night on draught—precious little sleep for eighty hours, but the evening being young, we are not yet prepared for sleep. We wonder at our wide-awakeness—tough lads of the right type assuredly, we tell ourselves.

Nothing else presenting itself, and the ascent to the dressing station not being enticing, we wander into the nearest dug-out. It is the telephonists' quarters. There is always something doing here, and the photographs that adorn the walls—Oh, those photographs! Those who know them demand no description; those who do not know them had best remain in the blessed innocence of their untainted manhood.

The Love of Music.

The French love music—worship it, fall over each other to catch a chord of its enchantment. I have a mouth organ, a relic of days in the Yukon—far off, thank goodness!—and give them a bar or two of "A Long, Long Trail a-Winding," with bits of my own thrown in. That opens the ball. It opens also a cupboard to the left, and from it emerges a bottle of colourless liquor they call Cognac. We drink to each other and to the end of the war. How weary of it we are! Yet why? We enjoy each day, we are free, we are happy, yet it is the weakness of humanity to count upon the sweetness of days to come.

That passes. We emerge into the night once more, the plaintive strains of a southern love-song echoing in our ears. It has turned colder—the mud is crisp under our gumboots, and, as we pause at the entrance, suddenly we realise how intensely weary we are. Sleep falls upon us like the pressure of a hand: irresistible, sudden, just as wakefulness comes in the morning. I recollect creeping into my sidecar stretcher, pulling the blood-stained sheepskins over me, and, after a struggle, buttoning myself in. No matter how cold it may be, we feel at that moment that nothing can disturb our slumbers.

How different the outlook when we wake an hour later! The first weariness is slept off: we feel ourselves to be machines once more—machines that dumbly obey orders, unquestioningly, mechanically, summoning up sense to do this and that, then working in a trance till this or that is completed. Such is the weariness of long hours of sleeplessness. We get up, shivering with cold, contrive to throw a blanket over the stretcher cover to keep out the frost, and that gives us another hour's sleep. When next we wake it is to move—after a sleepy speculation as to the practicability of warming the place with a *briquette*—to seek some other shelter; the sidecar, as we knew all along, is impossible for the cold hours of dawn this time of year, and so we toil up the precipitous path, under the camouflage of the firs, towards the dressing station.

Star Shells in the Night.

What a trip! Suddenly the whole sky flickers, and lonely and high soars a star shell, lazily, beautifully lighting the desolate, snow-covered uplands, so that the fir trees on the distant ridges stand out in silhouette. There is silence everywhere. Then comes that slow but murderous "tak-tak-tak" from the Boche's lines, followed by the quick and erratic fire of our own *mitrailleuses.*

Up goes another star shell and another. In the shadow of the firs we stand and watch and listen. Something tells us that a *coup de main* has started.

Words may be adequate for describing the ordinary conditions of life, but there are noises one cannot describe. It shakes the earth, it shakes the sky, and one decides that every man along a three-mile front must have handed in his check. For an hour it lasts—bewildering in its magnitude—then silence, a silence which seems veritably to hiss in one's ears: a part of the cold and the sudden blackness.

There are some prisoners, but we are told that, so far as we are concerned, the outcome is three wounded and one killed! It is almost incredible, and we wait by our sidecars till the solemn little procession, carrying its stretcher shoulder high, comes down the hill. By the light of a flashlamp we perceive a bundle of bloodstained bandages—no matter what he might have been, *procureur*, horse slaughterer, bigamist—even if we knew it would make no difference. To-night he is an innocent son of France, with an old, white-capped mother awaiting news of him, and we raise him from the narrow stretcher into the sidecar with the touch of love and brotherhood.

"Slowly, Monsieur?" we ask the doctor. "The route is very bad."

Pro Patria.—

The doctor shrugs his shoulders. "It is not necessary, Monsieur," he answers. "He is wounded in the head, and will feel nothing. Get back quickly for the next."

And so we let in the clutch, and set off over the shell-shattered road in pitch darkness. We have strapped our man down so that he cannot fall out or kick, but ten minutes of it awakens him.

Will one ever forget those cries, tearing at one's heart strings with every jolt—"La-la-la! Name of God, O name of God! Slowly! Slowly!"

We swallow our very hearts, for it must be done. Every cry is a living coal which burns indelibly into the mind, and time does not harden one. Silence falls at length, and we thank our stars for it. Through the scented moonlit forests we go, passing trains of *ravitaillement* and cannon, finding here that the whole bank has collapsed into the roadway since midday, the merest passage having been dug aside.

The Pathos of the Little Graveyards.

We gain the valley at length—still silence. To our right is one of those soldier graveyards that dot the roadside everywhere in these parts, with their pathetic little ornamental crosses, so characteristic of the French peasant. Aloft winter still reigns—here spring has dawned. The little graveyard is aflame with daffodils, and the fragrance of the place touches one when passing. Here, within sound of the cannon, within range of the guns, indeed, is a true resting place, fragrant with flowers, in the peaceful valley they have loved, and above it stands the great white cross—*Pro Patria!*—with its sheltering arms casting their shadows over the mounds of earth.

Soon we are within the region of civilians. We pause at a *Poste de Réconfort* to drink a cup of hot coffee—then on. It is daylight now. Through picturesque little villages we go, and on every bank flowers are blooming—often amidst the grim relics war. They are not picturesque, these war-time ruin for there is too much plaster and wallpaper abo them, yet it touches a strange chord when one sees cottage garden, well tended and ablaze with bloo while the cottage itself stands shell-shattered and roc less, long since deserted by those who still, doubtles call it home. There is nothing in this lovely regi but old people and shattered homes!

A sidecar ambulance waiting for the wounded. In the mountainous region of the Western Front winter still reigned when "Chinook" wrote this article.

The peasants cast but casual glances at the sidec with its screened suffere They are too accustomed the scenes and sounds of war-passing to and fro in an u ceasing procession for thr long years now—to note ther from what is taking place b a few miles away. Old wom scurry into the gutters to avoi the splash, then go their wa without second thought glance.

We arrive at the hospita A stretcher bearer casts bac the hood and looks within wit a quiet enquiry.

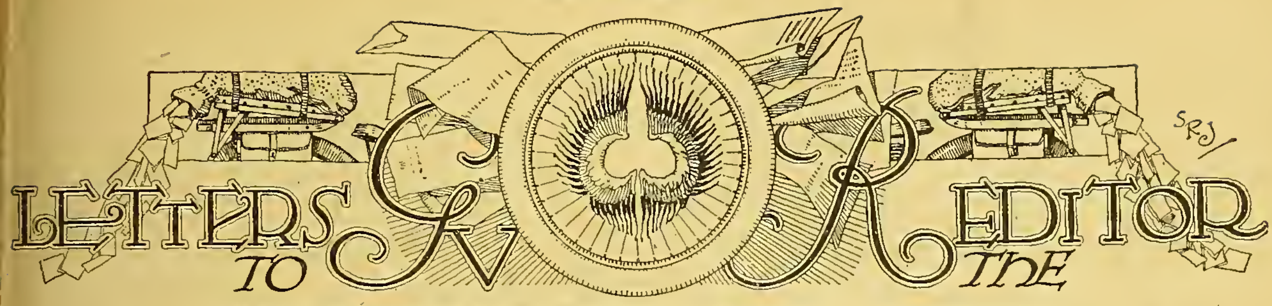
"You might have saved yo petrol, sir," says he, and w know now why our man wa silent. They lift him out, an hour ago we helped to li him in—a thousand times mo sacred now than then—and s the sidecars continue the work, generally at night-tim from the trenches to the bas They go where the cars ca not pass, or where, perhaps it is not worth while risking valuable vehicle. The suffe ing, the pity, the pathos of —fair sons of a fair land shattered in the twinklin of an eye into bloody, pitiable, moaning things—"Slowly, Name of God! O Slowly!"

Yet there is sunshine and laughter and song amids the pathos. To me there is no horror in it all. The come, they do their bidding with laughter and song and they go—go like men to rest honourably in quiet, flower-strewn place, amidst the scents an scenes they loved, within sound of the guns and th hurrying wheels of war's grim traffic. They go, mos honoured of all—*Pro Patria*. CHINOOK.

THE MOTOR CYCLE TAMER AND HIS VICTIMS.

"WE have bestridden some wild mounts in our time," writes an American journalist possessing the happy faculty of graphic description, "including the fiery Ormonde made for the Paris-Madrid race, but the wildest of the lot was Glen H. Curtiss's 10 h.p. single-geared racer.

"An unsuspecting friend of ours in New York State purchased this monster, and besought us to go out and break it in. As a precautionary measure, we lowered the gear. Even then the front pulley resembled the domestic bread trencher. There was something wrong with the primitive magneto, and to start the engine you had to cover the hundred yards in about 10⅖s. Anything less, and she refused to start, but if you were i good form you were rewarded by a premonitor rumble, which you instantly checked, making a ma leap for the saddle, and once astride, you could ope the throttle and discover a new chapter in life. You eyes streamed water, and you touched the saddl every quarter mile or so; railroad level-crossings yo never felt. Mazeppa would have appreciated her But we did not; she brought the grave too near, an we sold her to a college boy who told us he wante something 'that could hump.' He got it."



LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

WHAT HAPPENED.

Sir,—Returning from a ride I found my Triumph pulling badly. Examining the exhaust valve tappet I found the valve was being held up, and, as the tappet rod appeared to be seating correctly, I diagnosed stretched valve rod. As there was not sufficient adjustment in the adjustable tappet to get a thin card clearance (or indeed any clearance whatever) there was nothing for it but filing down the valve stem. I filed off $\frac{1}{16}$in. before I got any clearance. To my surprise, on starting up the engine, I found $\frac{1}{16}$in. clearance between the valve rod and the tappet table, and had to take it up by the adjustment. It looks as though the trouble was that the tappet rod was being held up, thus holding up the valve; but before filing the valve stem I had given the tappet rod a smart blow with a small mallet and failed to get it down to give clearance at the tappet table. The tappet rod appeared to work quite freely in the guide. What was the trouble? Will some expert diagnose it for me? AR 757.

CARBURETTER ADJUSTMENT.

Sir,—I am really very greatly obliged to your unknown correspondent who writes in your paper about my carburetters under the *nom de plume* of "Binker." I am sure his letters cannot help but be of great value to your readers.

It is very seldom, however, that we hear of a user who finds the adjustment difficult. Ninety per cent. of purchasers would endorse the letter in your issue of May 9th signed George B. Atkins.

I must, however, take exception to your correspondent "Excelsior" in the same issue.

I am quite certain that no one can fail to get the results claimed for the carburetter, provided it and the engine are in good order, and he take the trouble to understand it. In support of this, I will say that we have received more than ten thousand testimonials, and my carburetter was selected by Mr. Robbins when he entered for, and won, the much-coveted manufacturers' trophy. This most of your readers will remember as the great reliability trial.

Mr. Robbins writes me that months previous to the event he had carefully tested every other make of carburetter, and finally decided that the Binks carburetter was the one, in his opinion, that was most likely to give him success. In conclusion, may I say that I am at all times at the disposal of any of my customers who experience the slightest difficulty in getting the correct adjustment? CHAS. BINKS.

V TWINS OR FLAT TWINS?

Sir,—Recently I have read with much pleasure the letters of your correspondents praising the V or flat twin. At the same time, I was sorry to note that the arguments were always in favour of the machine and never of the rider. Many seem to favour flat twins for the reasons that they get even firing, and in consequence parts must last longer, the machine thus being practically vibrationless, etc. I record my experience, in the hope that it may be helpful.

I lost my left leg in a motor accident about twelve years ago. To carry on, I bought a V twin motor cycle (6 h.p.). I am sorry to say that after a short journey it was almost impossible for me to walk. The stump of my leg became absolutely black, and the circulation was much affected, the continual thump of the engine seriously interfering with the flow of blood.

My doctor advised me not to ride a motor cycle again. I then purchased a small car—the Marlborough. All trouble with my leg disappeared. With the war soon came shortage of petrol. I decided to sell my car and come back to my first mount, the motor cycle and sidecar, but my dilemma was how to avoid a recurrence of my former leg trouble. I got out of this in quite an accidental way. I live about ten miles from anywhere, and my dog being bad I sent for the veterinary surgeon. In conversation, I told him how I was situated, and he strongly advised me to get a Douglas, which, in his opinion, was the most comfortable machine on the market. Accordingly I secured a second-hand $2\frac{3}{4}$ h.p., used it every day, and was free from trouble with my leg.

As the machine was not strong enough to take a sidecar, I obtained from a friend the loan of a 5-6 h.p. V twin and sidecar. I regret to say that in a week, although the loss of my leg is twelve years old, the same trouble with my stump reappeared, and I was unable to use my artificial leg for some days.

A return to my $2\frac{3}{4}$ h.p. Douglas solo was the natural sequel. Some time later I had the luck to secure a 4 h.p. Douglas and sidecar, which I have continued to use day in, day out, without leg trouble. This will show to my unfortunate friends (who, I am sorry to say, are in great number) what make of machine is vibrationless and comfortable, and what to adopt when similarly circumstanced.

Whatever criticism may be offered of these remarks, nothing can alter the facts here set out. I have no interest in Messrs. Douglas Bros. E. G. FERY.

DIFFICULT STARTING.

Sir,—Some time ago I suffered from the difficult starting of my B.S.A. As I have now overcome the difficulty, perhaps my experience may prove useful to others. I bought the B.S.A. new a year ago, and up till recently used it daily, Sundays included, in my delivery work. As this work involved from 120 to 130 restarts daily, it will be understood that easy and *sure* starting was of first importance. It was the uncertainty of it that puzzled me. A carburetter setting that would give a good start when engine was warm, say at 7 a.m., was useless an hour later, and I was compelled to push. This was exhausting work.

I tried different oil, plugs, etc., and tuned up the magneto without effect. I mentioned it to a friend one day, and he lent me a Binks carburetter, which proved a complete cure. Starting from cold is *not* improved, and I have always to push when engine is cold, but once engine is warmed up I can *always* rely on an easy and sure kick start. I have no interest whatever in Binks, Ltd., and consider the price asked for the carburetter high.

When, however, I can again use the machine I shall buy a Binks. As regards the B.S.A., I have nothing but praise for its reliability. In the whole eleven months I used it it never failed, no matter what the weather. During the heavy snowfall of last winter I was able to climb all hills here (Weston-super-Mare) when big cars, etc., were hopelessly stranded. The chief trouble I experienced was control wires, etc., rusting up and becoming useless after heavy rain. And when a wire breaks on the B.S.A. with the inverted controls and enclosed cables it is a long and tiresome job to get at and repair. The outside wires score every time for accessibility. I also find it difficult to keep the spring fork spindles lubricated; but no doubt we shall get these details attended to when peace comes.

In conclusion, I would strongly advise any business man who needs an economical means of delivery to consider the B.S.A. motor cycle; the amount of neglect it will stand is astonishing. S.W.

PLUG TROUBLE.

Sir,—I have suffered from much plug trouble with my A.B.C., which seemed to be capable of carbonising the oil on the plug points in a dozen "revs," after a long coast, with the result that they were bridged by a granule of carbon. However, I fitted a Reliance plug to the back cylinder and an old four-point Bosch to the front (I cannot get a second Reliance), and have never had occasion to look at either since. Incidentally, while experimenting, I fitted an old plug with a heavy copper electrode; as this metal has the highest heat conductivity of all, except silver, it should be ideal where overheating occurs.

A relic which gave good results was an old E.I.C. mica plug, which has a rather interesting history. It was thrown away as a dud by Mr. S. F. Edge at the Bexhill meeting in 1903. It has run thousands of miles since, the original platinum points being burnt right away, and was changed from one machine to another for years. R. C. MEESON.

MOTOR CYCLE V. RAILWAY TRAIN.

Sir,—In your "Current Chat" of February 28th you gave an interesting account of a bit of a "dust up" between a Powerplus Indian and the Union Pacific passenger train. The run appears to have been over a distance of twenty miles, and the train had the advantage of being double engined. All the more credit, therefore, to the motor cycle outfit, which won by ten minutes.

Like all these American yarns, this is one which seems to bear very little investigation. The following queries at once occurred to me, and I have been waiting to see if any other of your readers has noticed the same and found the explanation difficult. In the first place, on a run of twenty miles the time taken could not have been much over thirty minutes, but the motor cycle outfit won by ten minutes—that is to say, the train would be seven or eight miles away behind, yet the passengers on the train cheered the driver when he pulled up at the crossing. We are not told which driver it was the passengers cheered, but it seems to me to have been equally superfluous for the passengers to have cheered their own driver for losing by ten minutes (at least, he might have heard them cheer) as to cheer the motor cycle driver who was seven or eight miles away, and could certainly not have heard their cheers even if they could *see* him.

J. G. IRVING.

[The explanation is quite simple. The train had eight minutes start, was overtaken by the motor cycle, which presently drew up at the level crossing and waited for the train to pass. The passengers then cheered the motor cyclist. We did not imagine that all these details would have been necessary.—Ed.]

THE FLAT TWIN CRITICISED.

Sir,—In his eagerness to dance on my mangled remains, it appears to me that "Chinook," in your issue of May 2nd, falls himself into three errors:

1. The common journalistic one of showing the absurdity of something your opponent did *not* say.
2. In not realising that the torque of a flat twin with one cylinder *definitely cut out* is as regular (though not as frequent) as if both were firing.
3. In again asserting that, from the point of view of comfort, etc., good balance is of more importance than good torque.

As the first two are merely personal questions between us, they can be of no interest to readers; but it seems to me that the views of experienced designers would be of interest on the third point. In support of my view, I claim that the four, which has not perfect balance, is more comfortable than a flat twin with three-throw crank, or a 90° twin, both of which can be perfectly balanced. Also that a cheap American eight-cylinder, the engine of which dithers in the frame, is sweeter to ride behind than a Rolls-Royce six. Also the fact that the internal combustion turbine is constantly sought after and sighed for.

I claim that these facts show that torque is more important to comfort than balance, and therefore make the vertical twin with single crank well worth considering among twins for motor cycle use, as it has very numerous advantages over the flat twin.

I would also like to enter a humble protest against the way all supporters of the flat twin beg the question on the subject of balance. Their remarks always contain such phrases as the following: "Its perfect balance" or "its vibrationless running." I have ridden hundreds of flat twins, the products of five different firms, but only one engine out of the whole lot was vibrationless at high speeds. (It had a three-throw crank, and other stunts not found on conventional flat twins.) All the other machines vibrated more, all out, than the single-cylinder Singers on which Stanley used to race. But they were more comfortable to ride than the singles. Why? Torque.

B.E.F. A TILTER AT WINDMILLS.

MOTOR CYCLING FOR THE MAIMED.

Sir,—My knowledge of motor matters is negligible, but, being disabled myself, I am interested, and I would like to make a suggestion which I would have carried out, had I the means, so that I could get to some employment.

My suggestion is the conversion of a suitable 2¾ h.p. motor cycle into a tricycle by substituting a pair of steering wheels on a light axle for the one steering wheel. The necessary alterations of the front portion would not, I presume, be a very great job for an engineer. An arrangement like this, it seems to me, would be much better than a sidecar attachment for a 2¾ h.p. machine; but, of course, you will know better what the suggestion is worth.

As to controls, alterations to these would differ according to the individual. In my case, I have sufficient use in the right leg to manipulate these, and have also the use of both arms.

I am not incapacitated through the war myself, but I sympathise greatly with our poor maimed fellows, the number of whom is becoming so great. IGNORAMUS.

Leeds.

[An attachment similar to that suggested has already been on the market.—Ed.]

HIGHER GEARS FOR SOLO RIDING.

Sir,—I should like to put forward an appeal for more infinitely variable gears. Can none of the many motor cycle gear experts produce a small and fairly light friction gear with ratios variable between 3¾ and 11 to 1 for medium weights, 3-10¼ to 1 for heavyweighs, and 4¾-12 to 1 for low-powered machines? "Ixion" is always asking for light gear boxes, and I think that the friction gear box could be made very light indeed.

At present if we want a multi-gear we are practically restricted to the Zenith or Rudge-Multi machines, although the Philipson and Grado gears have proved themselves very satisfactory, but they both lack an independent clutch.

Personally, I think the Zenith Gradua with a countershaft in front of the engine is the best on the market because of the lower ratios provided, but really I ought not to make this statement, as it has never been my luck to ride one. I have tried a Rudge-Multi, and I found it a delight to drive, but lacking a lower gear than 7½ to 1.

No one who has not tried a multi-gear has any conception of the pleasure derived from careful handling of the gear lever and the feeling that one is nursing the engine and getting the very best out of it; but, on the other hand, there is a certain kind of rider who will approach a hill on the top gear provided by, say, the Rudge-Multi, and wait until the engine begins to knock, and then yank the lever right back as if it were only a two-speed, instead of easing the lever back by degrees.

I remember reading somewhere an article about a very novel and interesting variable gear of the friction type called the Dallison gear, and that gear, to my mind, fills the bill exactly, because it could be adapted to suit chain or chain-cum-belt or even shaft drive. At first sight, this particular gear appeared somewhat complicated, but, once understood, seemed almost unbreakable and wear-proof.

I should very much like to know whether any attempt has been made to market the Dallison gear, and whether any machines will be available after the war fitted with it.

My ideal machine would be somewhat after the following lines. The engine would be a four-cylinder 8 h.p. air-cooled, with Binks carburetter, and C.A.V. magneto. The transmission a neat countershaft friction drive, infinitely variable between 3 and 10 to 1, XL-All saddle, semi-T.T. bars, 26in. × 3in. Palmer Cord tyres, quickly detachable wheels, an internal expanding brake on each wheel, and an accelerator pedal in conjunction with the usual hand levers.

Such a machine would be capable of very high speeds, and would be very docile in traffic owing to the multi-gear and accelerator pedal. ARGON.

POSITIVE VALVE OPERATION.

Sir,—*Re* statements about the Hinks valve in *The Motor Cycle* of May 9th, surely the cam which compresses the spring, and so closes the valve, has as much work to do as an ordinary cam has in compressing a spring and opening an ordinary valve? With the ordinary type of valve the cam has to work to force the valve open against the force of the compression in the cylinder (exhaust valve) and to compress a spring. With the Hinks valve, the opening cam has only the force of compression in the cylinder on the top of the valve to work against, but the closing cam has to work against a spring pressure, the same as in the case of the ordinary type valve, in order that the two types of valves may be held equally firmly on their seats.

Re "Induction Pipe Design," the ambition of the designer of induction pipes seems to be to put them where they can get as red-hot as possible. Surely the expansion of the indrawn air due to this heating will lessen the mass of gas drawn into the cylinder each induction stroke? The happy medium seems to be to keep the pipe just hot enough to supply the latent heat of evaporation to the amount of petrol being used.

BREEZY II.

Oxford.

[The spring in the Hinks valve is compressed about $\frac{1}{64}$**in.**, while the usual spring is compressed to the extent of $\frac{1}{4}$in., or sixteen times as much; it is also lighter. Hence the difference in work done.—ED.]

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—May I ask the favour of a few lines in your valuable paper to correct the impression given by "A Few M.T. Fitters, R.A.F.," in your issue of May 2nd?

Having had a varied experience both in Blighty and Overseas as a D.R. with the R.F.C. (now R.A.F.), I have never heard a more ridiculous statement than that no driver of either a motor cycle or car under any circumstances is allowed to do any repairs or adjustments whatever to his machine. Our P. and M.'s possess a moderate-size toolbag, but the makers seem to have overlooked the accommodation for the fitter, whose services would certainly be required on the long runs and conditions prevailing out here, especially during the past six weeks.

I conclude that "A Few M.T. Fitters" have had little or no experience with squadrons Overseas. May I ask, how many squadrons on active service have a motor cycle fitter on their strength? I know of quite a number without a single one of these important individuals, and all repairs and adjustments are done by the cyclists taking over the machines.

J.R.B.

B.E.F.

Sir,—May I be favoured with a small space to reply to "A Few M.T. Fitters, R.A.F.," in your issue of May 2nd, and also "A.F.C., Canterbury." During the past few weeks I have spoken to a number of fitters and cyclists on this matter, and they all are of the opinion that it is very unfair. The few who sign themselves "M.T. Fitters" may be exceptions. Coming nearer the point, we will suppose a cyclist is on the night stunt at headquarters. He arrives at a point twenty-five miles away from his unit. Snap goes his driving chain. Yes, only a chain breaks, but with the usual results. He finds those paper chain cases wrapped in the back wheel as usual. His orders must be at their destination before ten o'clock. He takes the sidecar off, and in half an hour the road looks like a tinsmith's shop. He looks through his spare parts, but he does not find an M.T. fitter, so he starts to reassemble and complete the job while those M.T. fitters are sleeping. Then he wonders why he should be classed non-technical. Doing repairs of this kind at the workshops in daylight, with all the tools necessary for the job, is not to be compared with it. When the order came out that a cyclist had not to keep his own mount serviceable I do not know. It is not so in the K.B.S. I agree with "A.F.C." when he says he would like to see every man go through a real test and get his 1st A.M. by his abilities.

OVER SEA.

B.E.F.

Sir,—I agree with "Six First-A.M.'s." It is absurd to class them as non-technical; but, at the same time, after what I have seen of the men and N.C.O.'s of this corps, I am inclined to doubt that promotion is an acknowledgment of efficiency. Perhaps they will think the same when they read the following two cases that came under my notice whilst "out West."

The first one concerns a man who went from second-A.M. to corporal in about five months. This same man put a Renault engine together five teeth out of timing. When his error was pointed out to him by a second-A.M., he wanted to know if it would matter.

Case No. 2 deserves to go down in the history of this war for all time. It concerns a flight sergeant. A machine had just landed; the pilot had got out and was standing by, when the sergeant asked him how it was going. The officer replied, "Fairly well, but I think there is one of the cylinders missing." The sergeant jumped on the skid, *counted the cylinders*, jumped down again, took a few regimental paces up to the officer, saluted, and reported, "Cylinders all present, sir."

Too idiotic to be true, you will think, but perhaps some of the R.F.C. Mons men will bear out the above cases.

Birmingham. RED, WHITE AND BLUE.

Sir,—May we be allowed to encroach a little on the valuable space in your correspondence column, heartily to corroborate the remarks that have been made by several of your readers concerning motor cyclists in the R.A.F. We all feel that an injustice has been done by classifying us as non-technical, when we continually do technical work under the most adverse circumstances. When at our particular squadrons or H.Q.'s, very exacting repairs and adjustments have to be made (often against time) with the minimum of facilities, and when on the road the quick delivery of despatches depends entirely upon the cyclist's ability to cope with any mechanical trouble likely to cause delay.

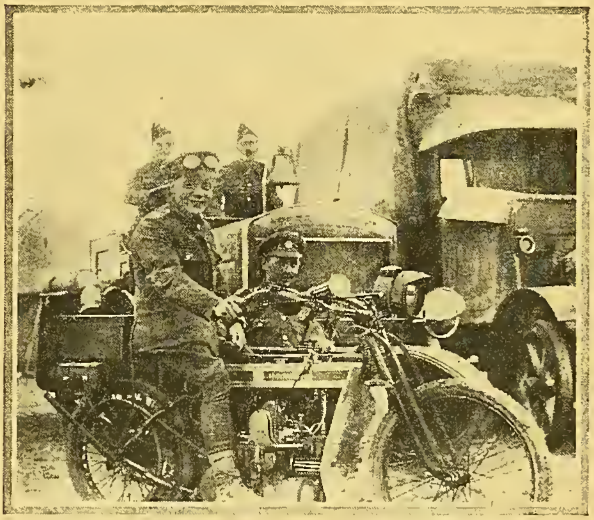
However perfect a machine may be, it is impossible to keep it at the high degree of efficiency demanded by active service conditions, unless the rider possesses a sound knowledge of "all the ills an 'iron' is heir to"!

Motor cyclists, as a body, are the least recognised of any of the "trades" in the R.A.F., in spite of their splendid work, carried out uncomplainingly under the vilest conditions, and it amounts to an insult when they are classified as non-technical.

For the person concerned in this "oversight" we recommend a few chilly battery runs, over prehistoric road surfaces, on a pitch black, soaking night! If during such a run he should be so unfortunate as to have a chain breakage, or other similar slight mechanical derangement, we feel confident that even such a trivial affair in the D.R.'s life would convince him of his inability to realise the true value of the R.A.F. cyclist's work!

D.R.'S, R.A.F. PATTERN (SIX OF).

B.E.F., France.

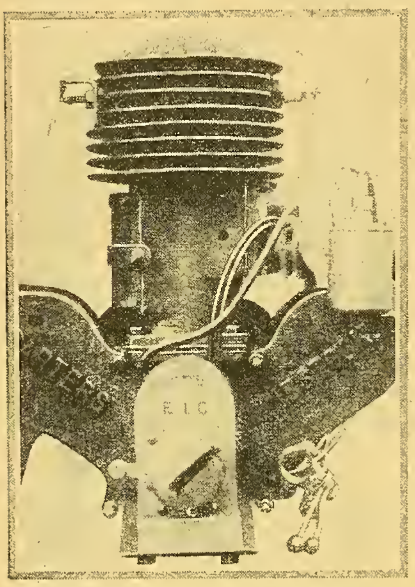


A.S.C. men aboard a Douglas sidecar outfit in Basra, Mesopotamia. Note the Merryweather fire engine.

A 500 c.c. TWO-STROKE.

A New Engine Unit for Post-war Motor Cycle Assemblers.

ALTHOUGH the comparatively large single-cylinder two-stroke engine so far has not proved a success, there appears to be no reason why a 500 c.c. engine of this type should not eventually be made to give results proportional to those of the smaller simple two-stroke engine. True, the difficulties appertaining to questions of lubrication and over-heating become disproportionately greater as the cubical capacity is increased; but there are many designers who maintain that had the larger type been given the same attention as has been paid to the lightweight engine these difficulties would have been overcome ere this.



The Carter 500 c.c. two-stroke. Note that the crank case, engine plate, and magneto platform are cast integral.

Mr. H. P. Carter, of Ibstock, evidently is of this opinion, as he has designed a 500 c.c. two-stroke engine with the intention of marketing it as a unit for the benefit of the many makers of motor cycles who prefer to leave the engine to those whose special study it is.

The first engine of the new design is here illustrated, and in fairness to the builder it should be remembered that the construction of such an engine at the present time is an undertaking fraught with many difficulties, which will explain the somewhat rough finish of the engine.

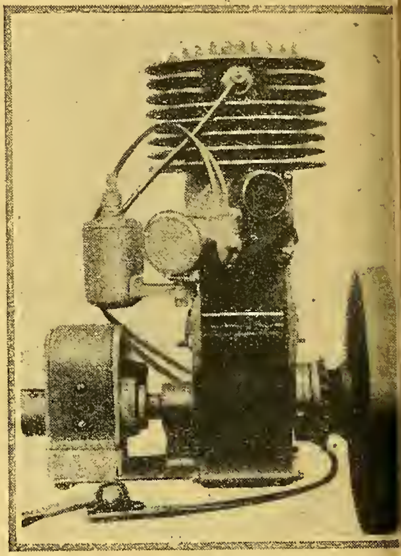
Novelty in Design.

The engine follows conventional two-stroke practice on general lines, but there are one or two novelties, *e.g.*, in the combined exhaust and inlet manifold and the magneto position.

It will be seen that in the Carter engine the crank case, engine plates, and magneto platform are cast integral, whilst the transfer passage has a detachable cover. The cylinder dimensions are the same as the usual $3\frac{1}{2}$ h.p. four-stroke, *i.e.*, 85 mm. bore and 88 mm. stroke.

Mr. Carter appears to have given special attention to the question of bearings, which are of ample size. The plain phosphor bronze bearing in the flywheel side is 3in. long, 1in. inside diameter, while on the magneto side the bearin is $1\frac{3}{4}$in. long. The big end bearing $1\frac{1}{4}$in. × 1in., and the small end of th connecting rod has a bearing $1\frac{3}{4}$in. × $\frac{1}{2}$i

The arrangement of flywheels and cran pin is the same as in the usual fou stroke, but, of course, smaller. Th fins on the cylinder appear to be on th thick side, but are very deep.



Showing the ample size of bearings on the Carter engine. A combined exhaus and inlet manifold is adopted.

* * *

A FEW SIDE-SLIPS.

Notes on "Ixion's" Criticism of "Skids and Skidding."

IT might be of interest to add a few details to my previous opinions on rough-rider mounts, with a special reference to the points raised by "Ixion" in his informative comments thereon.

The Scott.

The machine was slightly modified in so far that the front wind shields and the auxiliary silencer were removed; despite many falls (far more than one experiences in a season's joy-riding), nothing was broken, but I cannot say how many times the footboards were knocked off by dropping into deep ruts!

In the sporting event mentioned I suppose it goes without saying that the "well-known amateur" was the inferior rider, and, moreover, the falls he experienced were on hard, and possibly stony, roads, and taken at high speeds. Under such circumstances, breakages are almost inevitable, and it is quite likely that had he been riding a single-cylinder machine he would have scraped away all the radiating fins from the valve chest before the end of the journey was reached.

No! my contention for the Scott was this. Under conditions where the average rider would inevitably crash sooner or later, this machine is the most conducive to a postponement of the fateful hour—thus, if I were a doctor in a moorland village, with cart tracks to cover as frequently as roads, I should choose the Scott in preference to any other machine.

Unfortunately, I have not yet had the opportunity of testing the machine which "Ixion" has praised so long and consistently, but if the war last many more years I may be granted leave some day, and will hasten to become acquainted with later developments in the spring frame line.

Engines and Gears.

I am afraid we should never agree on this point. "Ixion" can tolerate a high revving engine at low road speeds and I cannot. Agreed that the torque of all types of engine is not radically different, and that all need a gear box, there yet remains the fact that some need the latter more than others.

To compare the Scott and Douglas. The latter was probably faster than the former, even on its middle gear, but on top it was too suddenly in difficulties with any falling off in speed, hence the second and low gears were constantly in demand, and the driving was largely don "on the gears"; the Scott would pull s slowly on top that in a sudden tigh corner there was always a permissibl slowing down period during which a comparatively leisurely change into low could be effected—in short, the driving was mostly "on the throttle," and infinitely easier when correcting recurring figures of eight.

Incidentally, it may be observed that the Douglas gear change is beautifully "slick"—a point which "Ixion" demands.

Road Surfaces.

These were indeed "truly impossible." One has merely to visualise rain-sodden pasture land over which some thousands of lorries, many with locked wheels, etc., have been towed.

In short, the man who would by choice ride over such surfaces may be classed with those referred to by a blunt Yorkshire farmer to whom I put the question, whilst I was in the midst of a single-geared, uncharted crossing of the Langstrothdale Chase, "Do many motorists come this way?"

Said he, "Noa! Nobbut a few foo-ils!"

WHARFEDALE.

QUESTIONS & REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Sizes of Jets.

Could you please inform me of the respective sizes of the three jets attached to the Binks-Douglas carburetter?—H.E.W.

We should advise you first of all to try jets 000, 1, and 7, and if this combination is not satisfactory, try experimenting with different sized jets according to Messrs. C. Binks's printed instructions. It is practically impossible to give you the exact combination of jets to suit any particular engine, but those mentioned are the average.

Valve Timing of 1911 Triumph.

Would you be good enough to tell me if the following is the best all-round timing for a 1911 3½ h.p. Triumph: Inlet begins to open on dead centre and exhaust to close on, or one tooth after, dead centre?—E.G.W.

The correct timing of the Triumph model mentioned would be as follows: The exhaust valve opens ⅜in. from the bottom of the firing stroke, and closes dead on top of exhaust and induction strokes. The inlet valve begins to open when the piston is at the top dead centre of the exhaust and induction strokes, and is closed when the piston has moved up ⅜in. of the compression stroke.

Accurate Valve Cam Design.

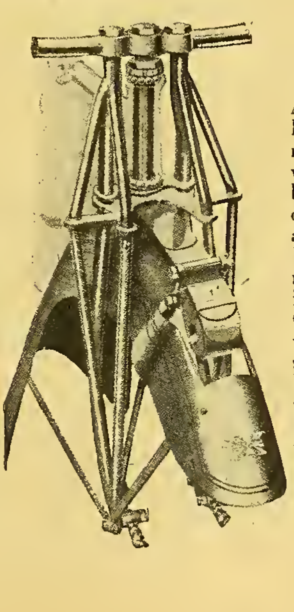
Can you recommend any book that gives diagrams and instructions relative to the design and setting out of valve cams for roadster and racing machines?—E.F.A.

You evidently want an exhaustive book on design which is not covered by the ordinary handbooks. We should recommend Vol. I. of "The Gasoline Automobile," by P. M. Heldt, price 23s., from the publishers of *The Motor Cycle*. Our ordinary handbooks, "Motor Cycles and How to Manage Them" and "The Autocar Handbook," give valve timing and diagrams, and, of course, deal with many other subjects also, but do not enter into the manufacturing methods adopted by engine makers. *The Autocar* diagrams of valve and ignition setting might be useful; these apply to four and six-cylinder engines. Most makers guard the cam design and setting of valves of racing engines as a manufacturing secret, and even the most talented engineers and designers differ in opinion on the subject. You will gather from this that there is no standard design.

Scott Gear Adjustment, etc.

I have just purchased a second-hand 1914 Scott motor cycle. (1.) When I bought the machine I was unable to have a trial run, but noticed that the low gear would not grip at all. I have taken the gear out of the frame, and noticed that there are washers on each side of the gear pedal. Are these for adjusting purposes? (2.) The machine is fitted with a two-jet Binks carburetter. Would the three-jet Binks give greater economy in petrol and slow running? (3.) Would you please state roughly the petrol and oil consumption of the Scott with the two-jet Binks, carefully driving at twenty miles per hour solo; also roughly the maximum speed on the level?—H.W.T.

(1.) The spring washers on either side of the quick thread drum are intended to lessen the shock of movement on the thrust rod. The small ¼in. washers on the thrust rod are a means of adjustment. With the aid of these it is possible to make the low gear pedal go further down or higher up. (2.) The three-jet Binks is a considerable improvement over the two-jet, especially as regards slow running, and with the former there is no hesitation when changing over from one jet to another, consequently it is more economical in petrol. (3.) It should be possible to get sixty to seventy miles per gallon solo, and two to three hundred miles per quart of oil. About forty-five to fifty miles an hour.



The new American Excelsior military fork, which has been specially designed for army service. It will be noticed that it is double-trussed to withstand side strain. For heavy sidecar work this improvement will be of great advantage.

The Safety Spark Gap.

When overhauling my magneto (ZEI), I found on the armature, which seems to be all covered up with insulating tape, *an end* of the wire, about ¼in. long, exposed and quite uncovered. What is this wire for?—D.H.J.

The wire in question is the safety spark gap, and is quite in order. It prevents undue strain on the winding and insulation of the armature if the magneto is allowed to run with the high-tension wire detached from the sparking plug or terminal on the magneto slip ring.

A Magneto Trouble.

I have purchased an old air-cooled twin-cylinder cycle car and a second-hand twin magneto. On trying to get the latter to spark, I find it will only do so when turned by hand. Immediately the chain is put on it refuses to spark at all. What can be the cause of this?—D.F.

A magneto cannot be short-circuited by its drive, and we can only suppose that the bearings are very badly worn and the pull of the drive causes the armature to touch the pole pieces at one end. This would not be the case when turned by hand.

Free-of-duty Petrol.

I am using my 3½ h.p. motor cycle with sidecarrier attached for conveying myself and material used in my business. I use it solely for this purpose, and always with the sidecar. I have a free-of-duty petrol permit for two trade motor lorries, and I use the petrol obtained for them for my motor cycle as well. I have not taken out a local taxation licence for the motor cycle, as I could not then use this petrol. The local taxation authority now want me to take out a licence. Under the above circumstances, can I legally use the motor cycle without a licence?—S.G.

If the machine is fitted with a sidecarrier box, bearing your name and business address, and the sidecar frame is secured to the motor bicycle by means of a steel pin driven through one of the nuts and bolts attaching it to the bicycle, so as to render the combination a permanent fixture, you are entitled to use free-of-duty petrol, and you need not pay the local taxation licence. If the combination were used once during the year for any other than business purposes you would become liable for the full tax.

Overhauling a Magneto.

I have a magneto which is out of order, and I cannot understand what is the matter with it. I can only get a small spark from it. Do you think it wants remagnetising?—D.L.

There is not very much that an amateur can do to a magneto in the way of overhauling it, but you might verify the following points: See that the carbon brush is making good contact on the slip ring and on end of armature at the back of contact breaker plate; also that the springs of these brushes are sufficiently strong to make good contact. If the ends of the brushes are polished, rough them over lightly with glass paper, and clean the slip ring by inserting a clean rag soaked in petrol and rotating the armature-shaft. Take off the contact breaker, clean the platinum points with a jeweller's file, and adjust them to break .4 of a millimetre or to gauge, and wash the contact breaker in a little petrol. If after that there is not a good spark, we should recommend you to send the magneto to a firm of repairers.

Loss of Power after Repairing.

I have a 4½ h.p. Singer combination. A short time ago I broke the big end of the connecting rod, and not being able to obtain a new one I had it welded, and on fitting it up I find that it is rather a tight fit on the crank pin. In taking down the engine we did not interfere with the timing gear side of the crank case, or the magneto, but got at the broken big end from the other side, removing one flywheel off the crank pin. After thoroughly cleaning the engine we have reassembled it in the frame, and it behaves as follows: It fires fairly easily, but the explosions are very slow, even when the throttle is fully open and are at about the same pace as when the throttle is a quarter open under previous conditions. When put into a lower gear and the clutch let in gradually the engine goes for a few yards, labouring the whole time, and then peters out. It will take scarcely any air. The symptoms are rather difficult to explain. We have seen that the following points are in order: (1.) That the carburetter is working perfectly, and there is a good flow of petrol, also that the induction pipe has no air leaks. (2.) That, upon placing the plug on the top of the cylinder, and wheeling the machine, a good spark occurs at the points. (3.) That the compression is good, as it skids the back wheel when the exhaust valve lever is dropped. (4.) That the gears are in order and the clutch not slipping.—B.A.F.D.

The trouble may be due to the big end being too tight a fit on the crank pin. If it is not abnormally tight this will remedy itself after a little use, otherwise the bearing may seize. If the trouble is not a tight bearing, the flywheel assembly is possibly out of truth. Run the engine gently, lubricate copiously, and see if there is any improvement. The carburetter and ignition are evidently in order. In all probability the reason that the engine will take practically no air is because it cannot get up enough speed to warrant it.

Speedometer Gear Ratio.

Can you give me the following information: I have a Jones speedometer on my 7-9 h.p. twin Swift runabout. It is driven from the propeller-shaft. The pulley on the speedometer cable is 4in. diameter. What should be the diameter of the pulley on the propeller-shaft? The back tyres are 710×85 mm.—J.R., Lt. R.A.F.

The information you require can only be supplied by the agents for your speedometer, Messrs. Markt and Co., Ltd., 100, Clerkenwell Road, London, E.C.1. There is a formula for working the ratio in the handbooks of some makes of speedometer, but not of the Jones. The Jones has usually an expanding adjustable V pulley.

The Wheel Mystery.

I have been arguing with a non-motorist to the effect that the top of a wheel when under speed on the road travels faster than the part which is in contact with the road, and he maintains that it is impossible unless the wheel gives to some extent. I should be much obliged if you would answer this for me and also inform me of the relative speeds of top and bottom.—C.S.J.

Your point of view is correct, for a vertical diameter of the wheel may be regarded as a lever, the fulcrum of which is the ground. Any point above the hub has a linear velocity equal to that of the hub (*i.e.*, that of the machine) *plus* a velocity due to the rotation of the wheel. Thus the total velocity of a point on its periphery vertically above the hub is double that of the machine. The bott point of the wheel is stationary. Th matter has been dealt with in the pag of *The Motor Cycle* several times, and most elementary article which explain it fully was published on April 17 1917, a copy of which issue you m obtain on application to our publishi offices, 20, Tudor Street, London, E.C

To Overcome the Difficulties Imposed by the Paper Shortage

□ □ □

At the present time, owing to the shortage in the supplies of paper for printing purposes, the production of newspapers is beset with difficulties, but by eliminating chance sales—with the consequent risk of copies remaining unsold, which leads to paper being wasted—it is hoped that the weekly demand for *The Motor Cycle* can be met, and all *regular readers* supplied with copies.

To those readers of *The Motor Cycle* who have given a definite order to their newsagents, the publishers tender their appreciation and thanks.

To those who have not yet done so, the publishers again make their urgent request that a definite order be placed at once.

Please give an order for "The Motor Cycle" to your Newsagent To-day.

Mending a Leaky Float.

(1.) Would you please tell how to get petrol out of carburetter float? (2.) Wh effect has a punctured float on t running of the machine?—A.F.

(1.) Drive a fine needle into the *top* the float, then put the float in a saucepa ful of hot water, stand it on a stove, a let the water boil. Petrol vapour w then be seen bubbling up from the origin hole *and* through the fresh hole ma with the needle. The boiling should continued until the float is entirely empt and then the leak and the hole you ha made should be skilfully soldered wi silver solder. If you cannot do this you self, mark the two holes and take the flo to a working jeweller, and ask him to u as little solder as possible. (2.) Whe the float is punctured it does not cut o the petrol, the carburetter floods exce sively, and the engine will stop.

Fitting a Magneto Switch.

(1.) Please tell me the advan tages and disadvantages of magneto cut-out. (2.) How t fit one to a two-stroke moto bicycle? (3.) If they are o advantage, why are not machines fitte with cut-outs when new? (4.) Wil such a contrivance injure the magneto —S.G.T.

(1.) The advantages are that you ar able to stop the engine independently o the exhaust lifter; consequently if th exhaust lifter wire breaks, you have means of stopping the engine other tha by throttling down. The only dis advantage is that there is an extra wir through which short-circuits may occur. (2.) Write to the makers of your magnet and ask if they supply a contact breake cover with a switch terminal. Buy a magneto switch from any accessory dealer, and connect a piece of low-tension wire from the switch terminal to the terminal on the contact breaker. (3.) Because the magneto and machine makers conside that the exhaust lifter and throttle are adequate provision for stopping the engine, and for the reason given in reply to 1. (4.) No.

RECOMMENDED ROUTES.

Basingstoke to Bexley.—F.J.D.

Basingstoke, Odiham, Farnham, Guildford, Leatherhead, Sutton, Croydon, St. Mary Cray, Bexley.

Rugby to Halstead.—H.R.

Rugby, Northampton, Yardley Hastings, Bedford, Great Barford, Eaton Socon, St. Neots, Cambridge, Linton, Haverhill, Halstead. To return *viâ* Newmarket, we should recommend you to go *viâ* Sudbury, Long Melford, and Newmarket to Cambridge, thence by the route previously given.

When the War ends

and you once more use your bike, do away with pre-war standards of efficiency and fit the C.A.V. MAGNETO Tested by War and found unequalled

Economical Insurance for Motor Cyclists

PROVIDENT ACCIDENT AND GUARANTEE COMPANY, LIMITED,

FORMERLY KNOWN AS
THE PROVIDENT CLERKS' AND GENERAL GUARANTEE AND ACCIDENT CO., LTD.
ESTABLISHED 1865.

REASONABLE POLICY CONDITIONS. PROMPT SETTLEMENT OF CLAIMS.

£10 REWARD.

£10 will be paid for information which may lead to the recovery of a "Royal Enfield" 6 h.p. Combination. Registration No. MX 6681, Engine No. W 5071. Special screen and hood, Watford speedometer No. 70S, 1915 make. Also the same amount will be paid for similar information leading to the recovery of a 1914/15 3½ h.p. Twin "Zenith." Engine No. 52830, mag. chain case slightly damaged. "Matchless" 8B Model, Engine No. 34572, Frame No. 3041, Regd. No. LR 3766 undertank tube cracked at head.

H.P.	PREMIUMS FOR PRIVATE USE ONLY. **VALUE OF MOTOR CYCLE and SIDECAR.** Not Exceeding £50.	Exceeding £50.
Under 3½	£2 7 6	£2 10 0
3½	2 10 0	2 15 0
4½	2 15 0	3 0 0
5—6	3 0 0	3 10 0
7—9	3 17 6	4 7 6

15% REDUCTION IF INSURED BEARS THE FIRST £1 OF ALL CLAIMS.
25% " " " " £2 " "

Extra benefits and Personal Accident Insurance included at slightly increased premiums.

BARGAINS

The following machines speak for themselves. We make no further comment.

SELECTION FROM STOCK.

1.	**A.J.S.**, 1915, 2¾ h.p., 2-speed, clutch, kick-starter	39 gns.
2.	**ALLON**, 1918, 2-speed, 2-stroke, clutch, as new	35 gns.
3.	**ALLON**, 1916, 2-speed, 2-stroke	26 gns.
4.	**AMERICAN EXCELSIOR**, 1917, 8 h.p., Combination, dynamo lighting	85 gns.
5.	**BAT-J.A.P.**, 1914, 6 h.p., 3-speed, 2-seater Sidecar	39 gns.
6.	**B.S.A.**, 1913, 4¼ h.p., 2-speed, clutch, pedal-start	25 gns.
7.	**B.S.A.**, 1916, 4¼ h.p., 3-speed, chain-cum-belt, perfect	53 gns.
8.	**BRITISH EXCELSIOR**, 1916, 2½ h.p., 2-speed, clutch, 1916	25 gns.
9.	**CALTHORPE-J.A.P.**, 1915, 2-speed, re-enamelled	24 gns.
10.	**CALTHORPE**, 2-stroke, 1915, 2-speed	23 gns.
11.	**CAMPION-J.A.P.**, 1915, 4¼ h.p., Jardine 2-speed gear box	37 gns.
12.	**DOUGLAS**, 1913, T.T., 2-speed	27 gns.
13.	**DOUGLAS**, 1916, 4 h.p., T.T., 3-speed, good order	59 gns.
14.	**DIAMOND**, 1916, 2-speed, 4-stroke, clutch	26 gns.
15	**ENFIELD**, 1916, 6-8 h.p., Colonial model Combination	72 gns.
16.	**ENFIELD**, 1916, 6 h.p. Standard Combination	69 gns.
17.	**ENFIELD**, 1916, 3 h.p., 2-speed, clutch, kick-start., as new	39 gns.
18.	**ENFIELD**, 1915, 3 h.p., 2-speed, clutch, kick-starter	32 gns.
19.	**F.N.**, 1913, 5-6 h.p., 2-speed, clutch	28 gns.
20.	**HUMBER**, 1918, 6 h.p., 3-speed, flat twin Combination, 3-speed	85 gns.
21.	**HUMBER**, 1918, 3½ h.p., 3-speed, flat twin, 3-speed	£75 0
22.	**INDIAN**, 1916, T.T., 5-6 h.p., 3-speed, disc wheels	48 gns.
23.	**INDIAN**, 1915, T.T., 7-9 h.p., clutch model	37 gns.
24.	**INDIAN**, 1916, T.T., 7-9 h.p., clutch model, disc wheels	48 gns.
25.	**INDIAN**, 1914, 7-9 h.p., 2-speed Combination	49 gns.
26.	**INDIAN**, 1914, 7-9 h.p., 2-speed, spring-frame	35 gns.
27.	**IVY-PRECISION**, 1915, 4¼ h.p., 3-speed	29 gns.
28.	**JAMES**, 1914, 4¼ h.p., 3-speed	34 gns.
29.	**JAMES**, 1916, 2½ h.p., 2-speed, 2-stroke, re-enamelled	26 gns.
30.	**J.H.**, 1916, 8 h.p., M.A.G., Sturmey gears, coach Sidecar	89 gns.
31.	**LEA-FRANCIS**, 1915, 3½ h.p. twin J.A.P., countershaft	46 gns.
32.	**LEVIS**, 1916, Popular, as new	21 gns.
33.	**MATCHLESS**, 1916, 8 h.p. M.A.G., Lucas dynamo lighting Combination	79 gns.
34.	**MATCHLESS**, 1913, 6 h.p. J.A.P., 2-speed Combination	35 gns.
35.	**MATCHLESS**, 1918, new War Model Combination, spare wheel	£125 0
36.	**MATCHLESS**, 1915, 8 h.p. J.A.P., 3-speed coach Combination	59 gns.
37.	**NEW HUDSON**, 1916, 2-speed, 2-stroke	24 gns.
38.	**NEW HUDSON**, 1915, 6 h.p. coach Combination, 3-speed	52 gns.
39.	**NEW HUDSON**, 1914, 6 h.p., 3-speed coach Combination	45 gns.
40.	**NEW HUDSON**, 1915, 4 h.p., 3-speed coach Combination	37 gns.
41.	**NORTON**, new 1918 Military Model, 3-speed	£82 10
42.	**N.U.T.-J.A.P.**, 1915, 3½ h.p. twin, 3-speed, disc wheels	48 gns.
43.	**NEW IMPERIAL**, 1916, 2-speed J.A.P., as new	29 gns.
44.	**PREMIER**, 1914, 3½ h.p., 2-speed countershaft	29 gns.
45.	**PREMIER**, 1914, 3½ h.p., 3-speed Combination	36 gns.
46.	**PREMIER**, 1915, 2½ h.p., clutch, lightweight, perfect	22 gns.
47.	**RUDGE-MULTI**, 1917, I.O.M., sloping tank, as new	58 gns.
48.	**RUDGE-MULTI**, 1914, re-enamelled	37 gns.
49.	**RUDGE**, 1915, 5-6 h.p., 3-speed, Rudge coach Sidecar	45 gns.
50.	**ROYAL RUBY**, 2½ h.p., 2-stroke, re-enamelled	22 gns.
51.	**SCOTT**, 1914, coachbuilt Combination	37 gns.
52.	**WOOLER**, 1916, 2-speed, 2-stroke, as new	29 gns.
53.	**WILLIAMSON**, 1915, 10 h.p., water-cooled Combination	59 gns.
54.	**ZENITH-GRADUA**, 1916, 4-5 h.p. twin, as new	49 gns.
55.	**ZENITH-GRADUA**, 1915, 4-5 h.p. twin sporting Sidecar	49 gns.
56.	**ZENITH-GRADUA**, 1915, 8 h.p. Combination, hood, screen	59 gns.

RIDER TROWARD & Co.

The Book that Saves TIME, TROUBLE, and TEMPE

TRACING TROUBLE

MOTOR CYCLE FAULTS,
THEIR IDENTIFICATION
AND THEIR REMEDIES.
SIMPLY AND FULLY
EXPLAINED.

THIS handy little volume deals with all the faults to which motor cycles are liable, explains how they can be easily diagnosed, and shows how they can be rectified.

Every conceivable cause of trouble is dealt with, and the remedy for it carefully explained.

It is written in simple language by a practical motor cyclist of long experience, and fully indexed for ease of reference.

Obtainable from—
ILIFFE & SONS LTD., 20, Tudor Street, London, E.C.4, and leading booksellers everywhere.

Third Edition
(Second Reprint)
Now on Sale.

Price 2/- net.
By Post
(Home or Abroad),
2/2.

The AUTOCAR HANDBOOK

A Guide to the Motor Car.

Full of practical and useful information for all car owners.

Seventh Edition, Price 2/- net. By post 2/5.
Home or Abroad.

Obtainable from ILIFFE & SONS LTD., 20, Tudor St., London, E.C.4, and leading booksellers.

Faults and How to Find Them.

A system of locating faults in motor cars, applicable to all makes, with a full explanation of the remedy for each fault.

Specially useful to the owner-driver.

Price 2/6 net.
By Post Home or Abroad, 2/9

Obtainable from the Publishers:
ILIFFE & SONS LIMITED, 20, Tudor Street, London, E.C.4,
and all leading booksellers and bookstalls.

Preparation of Post-war Models.

WE wish particularly to draw the attention of all British manufacturers of motor cycles to the letter published on another page from the chairman of the Motor Industry Branch Committee of the Engineering Trades (New Industries) Committee of the Ministry of Reconstruction. We referred a few weeks ago to the formation of this Branch Committee, and on enquiry we ascertain that the direct representation of the motor cycle interest upon it is now assured by the inclusion of Mr. J. W. Stocks, of Components, Ltd., and Mr. C. A. Hyde, of the B.S.A. The object of the Engineering Trades Committee is the development of new industries and particularly of the manufacture in this country of products previously imported from abroad. It is, however, very difficult to distinguish exactly between a new industry and a new product of an established industry, and, therefore, it is only reasonable that the Committee should include within its scope the encouragement of the production of new models representing improvements over those manufactured before the war. Moreover, now that the great majority of motor cycle manufacturers are building almost anything but motor cycles, it is quite evident that, unless they can make real practical progress with their after-war plans while the war is still going on, there will be a long hiatus between the conclusion of peace and the production of new types of motor cycle. It may be that some manufacturers will feel that their requirements as regards materials are so insignificant that they will be able to proceed with the preparation of their plans without making any special requisition for supplies. Now, it would obviously be impossible to make application for labour through the official channel without making a simultaneous application for material. Without the material the labour cannot be used, and if the use of material had not been authorised, questions would naturally be asked as to how the labour was going to be employed were it rendered available. Under all the circumstances, we strongly advise every manufacturer of motor cycles or accessories to make his application in the proper form through this Committee. It would not be safe to take it for granted that the Committee will be able to obtain everything the manufacturer wants. Much depends on the Priority Department, and we all know how difficult it is to get authority to use either labour or material for any other than immediate war purposes.

Journalistic Self-respect.

WE wish to endorse most heartily the comments made in *The Autocar* last week on advertisements in the guise of editorial matter. The facts are: An advertising agency secured the insertion in various journals of what purported to be editorial articles, though the space they occupied was paid for. These articles dealt with political matters, about which we do not intend to express any opinion, but we think there can be no two opinions on the policy of any newspaper which lends its columns to such a scheme.

The principle maintained by *The Motor Cycle* and its sister journals is that the editorial and advertising departments should be kept entirely distinct. The editorial side is reserved for the expression of views which are, in our opinion, best in the interests of our readers. These views may or may not coincide with the opinions of our advertisers, but in this way only can a journal arrive at an authoritative position in its own sphere, and one in which it can be of real use to reader and advertiser alike.

We refer to this unpleasant matter only and solely because we wish to emphasise our opinion that journalistic self-respect and commercial policy are coincident when the editorial and advertisement sides of a journal are kept quite separate.

An index to the advertisements in this issue will be found on the page facing the back cover

OCCASIONAL COMMENTS

BY "IXION"

An Alternative to the Dynamo.

I HOPE the British trade will not let itself be stampeded into dynamo lighting for motor cycles after the war without mature consideration. I quite admit that a good dynamo set is probably the perfect light, but I still suffer from misgivings on its application to motor cycles, and especially to bicycles unadorned by sidecars. The dynamo set is weighty and expensive. It is made or marred by its accumulator, and though I have tested practically every accumulator, including two or three specially manufactured for bicycle use, I have yet to try one on which I would gamble in any important ride by night. Again. the low price limits of two-wheelers are sure to create a demand for cheap sets, and ignorant buyers will foster this demand. I have a variegated experience of cheap dynamo sets, in which cheapness was determined by a far higher price limit than motor cyclists can ever afford, and, frankly, I distrust the cheap dynamo. Yet again I notice that American designers are either extremely optimistic or extremely dishonest where cheap electrical goods are concerned. They pass stuff which would provoke the shoddiest British manufacturer to clump the seller over the head with a crankshaft. But even the purveyor of the cheapest American stuff is apt to shy at electric lighting for motor cycles, and to pin his faith to the Prestolite.

The Prestolite System Anglicised.

IT has been a source of wonder to me for years that the Prestolite system, corresponding to the British D.A. (dissolved acetylene) products, has never made good over here. To judge by what one reads of American roads, night riding in the States must be some proposition. Neither is there a repairer round every corner, nor a friendly depot within a mile or two of every potential breakdown; yet the dissolved acetylene system has been almost universal in the U.S.A. for years, so far as motor cyclists are concerned. You cannot open an American technical journal without encountering huge displayed advertisements of it; nearly every photograph of machines in use in America reveals the familiar storage tank.

Experiences with D.A.

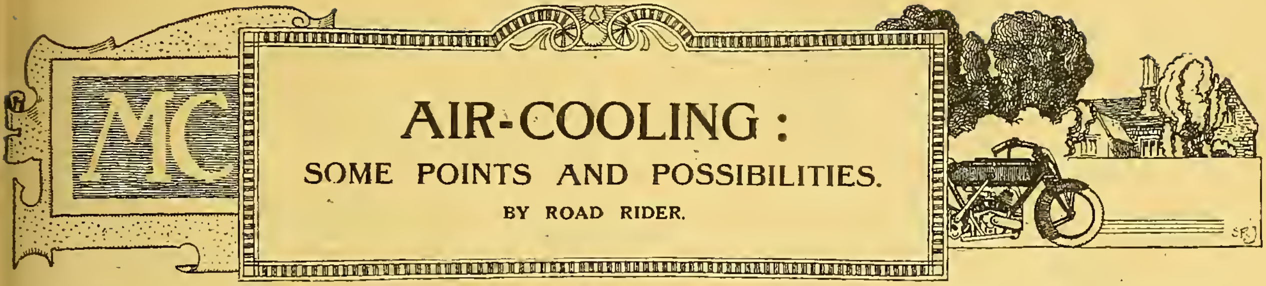
I HAVE hardly used the dissolved acetylene on cycles for reasons which I will presently expound, but I have given it prolonged tests on cars and cycle cars, and to my mind it has the acetylene generator beaten to the wide, and whilst equalling a first-class dynamo on every point except the substitution of a match for a switch, it beats any dynamo made on first cost. To sum it up, it ensures you a permanently clean burner, instantaneous lighting up, guaranteed light without any flickers or jumps throughout a whole night ride, and all this at a very low cost. It is as clean as electricity, and a leaking connection is the sole trouble you need fear. Moreover, an acetylene leak is far easier to trace and repair than a wiring fault.

The Cause of its Obscurity.

THE simple fact is that the D.A. Co. has never inaugurated a proper publicity and supply system in this country. The demand for the cylinders especially in the baby size, has never been great, and the vendors presumably could not afford to splash a few thousands on winning a market. Nobody dreams how good the stuff is. A few individuals, like myself, are aware that the cylinders probably afford the best and cheapest lighting available for small motors and we invest, only to run our heads against two snags, neither of which need complicate the position for a day if stringent measures were taken. In the first place, the smallest size of cylinder is either a little too large for motor bicycles, or the wrong shape. You can house it, but the American Prestolite Co. is far cleverer at greasing the slips for its customers (doubtless because it can reckon on some big trading). Secondly, the depots at which spare baby cylinders can be obtained are few and far between (again owing to the limited demand, which in turn is due to poor publicity). Thirdly, any lighting system based on storage cylinders is only ideal when duplicate cylinders are carried, just as no electrical enthusiast ever feels really cosy unless he has a spare battery aboard. We can house one cylinder of the existing dimensions on a bicycle, but we cannot house two. When our solitary cylinder is nearing the empty point, we feel it will be wise to exchange it at the first opportunity. We get no rebate on the whiff of gas remaining in the old cylinder, and we cannot bear wasting it, just as a hardened toper usually swigs his dregs. If the D.A. people care to market sets consisting of two small-sized cylinders, and take steps to inform motor cyclists that they can offer a sound lighting proposition, the cheap dynamo will be gingered up to show what it can do, and it will not prove a winner even at that.

Cleaning the Sparking Plug.

PREVENTION is better than cure, and air mechanics do not wait for a sparking plug to soot up in use. They inspect, and if necessary clean, all plugs at regular intervals. If motor cyclists adopted a similar routine, they would protect themselves from annoying stops by the roadside, and save their plugs from being stove-enamelled a rich black during long periods of inattention. If a plug does not lend itself to cleansing by means of a wire brush or other scraper, it is a good tip to immerse it in a tin containing a strong solution of washing soda, stand the tin in a pan of water, and boil the lot for ten minutes or so. The double container is advised because the soda solution boils over rather readily.



AIR-COOLING:

SOME POINTS AND POSSIBILITIES.

BY ROAD RIDER.

Our contributor in this article illustrates the great advantages that would accrue from alteration in the design and manufacture of motor cycle cylinders and combustion heads. He argues that if they were made on the lines of aircraft engines with steel cylinders, greater uniformity would result, and such cylinders would not tend to warp unduly under the influence of variations of temperature at different spots in the combustion head and the fluctuations of cooling draughts. It should be borne in mind, however, that cost is hardly considered in air engine production, and steel cylinders require extremely accurate and expensive machine tools to make them commercially possible on any but the most expensive motor cycles.

SOME of us have been rather "narked" during the past four years by the contemptuous way in which the brass hats of the R.A.F. regard our dearly beloved motor cycle engines. But, after all, *we* did not design these despised power units, and it may be that the scoffs we have resented are rather intended to lighten our lot in the future than to break our heads. So let us have a look at a typical pre-war air-cooled engine, see if the criticisms are justified, and if the "prognosis" (as the Harley Street specialist calls his prophecy that your cancer will recur in two years) is favourable.

Motor cyclists are all one family, and inside the family circle we do not mind confessing that some of our pre-war engines possessed certain serious faults, all of which point to inefficient cooling.

For Example.

1. Many were very fastidious about sparking plugs: the queries columns of this journal used to bristle with sparking plug troubles. The trouble was usually that, if a plug had a very thick electrode, it sooted up; if it had a very thin electrode, it became incandescent. (*Heat* is the obvious culprit.)

2. On the rare occasions when a standard touring engine was driven all out for several miles, it incontinently had a fit of what the Purple Pill advertisements call "that tired feeling." The popular theory was "incandescent sparking plug electrodes." (*Heat* once more.)

3. The hotter our engines got, the worse they ran. This was true, even if they did not "konk out" altogether. In particular we noticed that the compression got weaker and weaker, as the engine grew hotter, suggesting that the various "compression seals" (valves, piston rings, etc.) had shrunk or grown lob-sided, or "distorted."

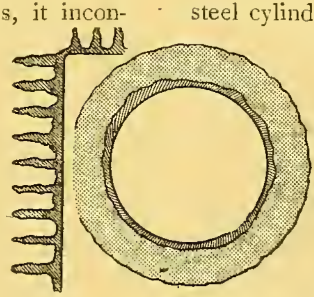


Fig. 1.—Sections showing in an exaggerated manner the irregular walls of a cast iron cylinder.

Oil-cooled not Air-cooled Engines.

4. We were compelled to use lashings of oil. Scoffers always said that our alleged "air-cooled" engines would better be described as "oil-cooled." Whether this was true or not, we undoubtedly used too much oil, and we had to splash it into the crank case in great dollops every four miles or so: for when the constant trickle "drip feed" was introduced, the number of engine repairs went up by leaps and bounds, so that leading manufacturers hastily reverted to the hand pump. (*Heat* again.)

5. Of this absurd oil consumption, a large portion slowly baked itself into a hard crust and deposited itself over the piston tops and the interior surfaces of the combustion chamber. Fortunately we could whip our cylinders off much more speedily than could the owner of any other type of motor: and then we dug the filth off with chisels and glee. (*Heat* again.)

6. Pre-war motor cyclists periodically laboured at a spare time occupation known as "valve-grinding." Alternatively, they sent their valves back to the factory to be refaced in a machine tool. The valves became pitted far more rapidly than those of a water-cooled engine. (*Heat* again.)

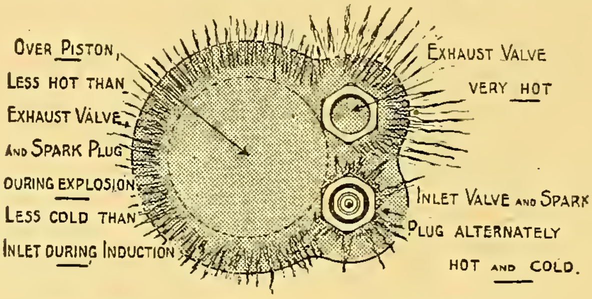
Heat—its Causes and Cure.

I now propose to desert symptoms and to pry into causes and cures.

In the first place the 1914 engine possessed in practically every case a cast iron cylinder (I believe the steel cylinders of the A.B.C. were the sole commercial exception). One face only of these cast iron cylinders could conceivably be true, namely, the internal bore, which was accurately machined and ground; in other words, the hollow in the cross-section was a true circle. The exterior of the cylinder was not machined, either because of the cost of entering a tool between each pair of radiating fins, and the difficulty of gauging when such a tool had bitten down the wall to the exact thickness required, or because the rough metal radiates heat better than a perfectly smooth surface. Neither was the exterior cast dead true, because—regardless of expense—absolute accuracy in the coring of such an intricate piece of foundry work is a sheer impossibility. In other words, a cross-section of a cast iron cylinder wall (taken between two fins), as exaggerated under a magnifying glass, would appear something like the caricature in

Air-cooling.—

fig. 1. Now, supposing that such a wall was machined true inside, received an even degree of heat all round in working, and received an even draught all round in motion, it could not possibly hold its internal bore truly, because the radiation of heat from such an irregular section would always be irregular. One part must be hotter than another. Expansion varies all round the wall. The wall warps.



Over Piston, Less hot than Exhaust Valve and Spark Plug during explosion. Less cold than Inlet during Induction
Exhaust Valve very hot
Inlet Valve and Spark Plug alternately hot and cold.

Fig. 2.—Showing local variations of heat in combustion head.

Where Warping has the Most Effect.

Warping of the wall towards the foot matters little, as the base of the wall is rather an oil retainer than a compression holder. The lower half of the cylinder barrel has nothing much to do with retaining the compression, and exists chiefly to hold the cylinder head on, to prevent oil from escaping, and to provide a bearing for the piston. But the nearer we get to the head of the cylinder the more disastrous are the effects of the warp. Increased piston friction occurs at one point, oil escapes at another, compression leaks at another—these are some of the obvious consequences.

So far we have pretended that the reception of heat was even all round the wall. This is simply a grotesque lie. It is just as uneven as it can be. Fig. 2 is a plan of the combustion chamber or cylinder head. It shows first a very hot spot on the right front, where the exhaust valve lives in an inferno of flame; secondly, a peculiar spot alternating between the temperatures of the tropics and the pole at the right rear, where the ice-cold entering gas freezes the neighbourhood once in each cycle, and the nucleus of a hell-burst of detonation almost melts the sparking plug a fraction of a second later; thirdly, a comparatively temperate zone, occupying the whole of the rest of the combustion chamber.

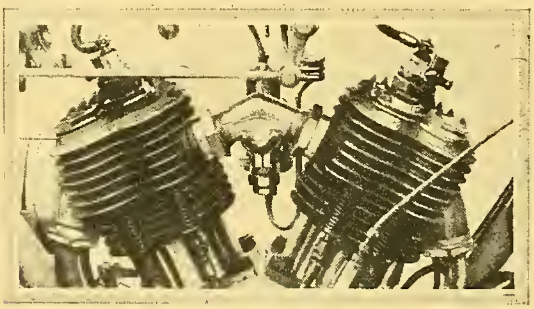


Fig. 3.—Present-day type of side valve cylinders, valve caps, and guides, showing their general "knobbiness."

Inequality of Surface in Combustion Heads.

The top of the cylinder is obviously the place where variations of temperature with their consequent warps and distortions are mostly to be feared (fig. 3). But this cylinder head, too, is a casting: a casting with all the inevitable inaccuracies of castings which are largely unmachined, and—worst of all—a casting which literally bristles with knobs and humps and lumps of metal, callously incorporated in it from sheer want of comprehension. The casting is so complex that only a photograph of a section made at umpteen points can give any notion of its glaring absurdities. But to name a few of the protuberances, we have a large boss bang in the centre of the head, which carries a dope hole, commonly known as a compression cock, because some of the compression is usually leaking through it. On the right rear and front we have two huge amorphous warp-producing blobs of metal known as valve caps, which will continue to singe asbestos for ten minutes after extraction from a hot engine. Beneath them are valve guides, which are usually well blued with heat over much of their surfaces after the first five minutes run of a new engine. The exhaust pipe, and its heavy connection, store up a lot of heat, and hot air from them blows back on to the rest of the long-enduring flank of the engine. The more we consider the warping possibilities of this monstrous abortion known as a combustion head the more we marvel that it retains any pretension of shape afte ten miles at 30 m.p.h.

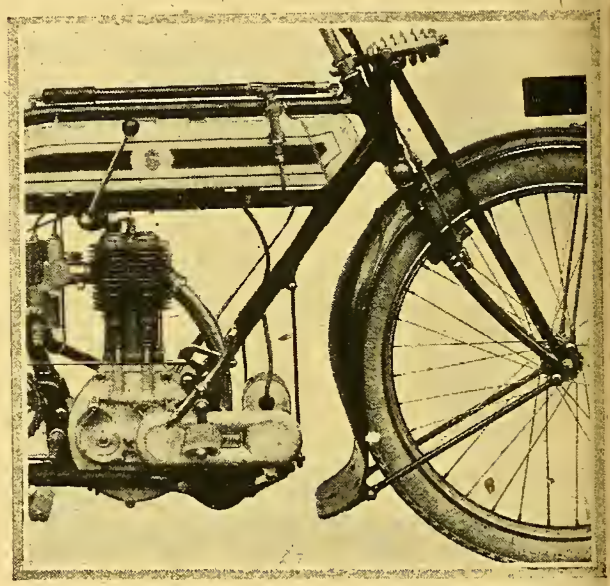

Fig. 4.—The 3½ h.p. vertical single, illustrating the remarks on draught obstruction.

The Effect of Draught.

Moreover, in the preliminary study above, we pretended that the draught on the entire periphery of th cylinder was even. As a matter of fact, it is impossible that this draught should ever approach evenness, however distantly. To begin with, we cannot b certain that there will be any draught at all, for th machine may be travelling at 30 m.p.h. with a 3 m.p.h. wind dead astern. Secondly, we cannot gues

Air-cooling.—

from what direction the draught, if any, will be coming, for the machine travels along the ever-changing line of the road, and the wind does not adjust itself to the route we have mapped. Thirdly, an unknown percentage of the draught will be diverted before it reaches the cylinder; immediately in front of the cylinder there are various bulky fittings, to wit, an exhaust pipe, a magneto, at least five steel tubes (front down tube of frame, two fork tubes, and two fork girders), a mudguard almost as wide as the cylinder, a revolving wheel causing the most intricate atmospheric disturbances which vary eternally with wind speeds and wind angles, a tangle of control wires, support stays, a mudsplasher, etc., etc. Fourthly, the draught (if any) bounces off the irregular surfaces of that face of the cylinder which it hits, and jumps past the sides of the cylinder, missing its remoter face altogether (fig. 4).

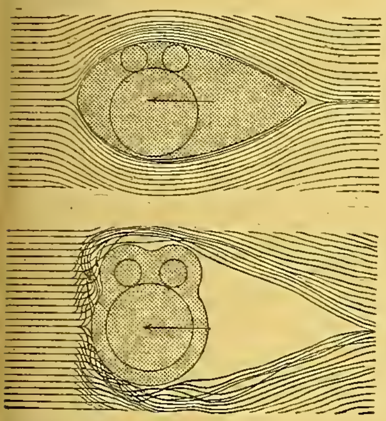

Fig. 5.—Diagrams depicting the behaviour of draughts on a stream-line cylinder head and on a side valve cylinder head. In the second sketch, note the vacuum behind the engine and failure of draught to reach the rear head.

In other words, when there is a draught at all, an unknown percentage of that draught impinges on the nearest face of the cylinder, and the remoter face of the cylinder receives no draught at all.

Improving the Cooling by Better Design.

Summing up the result of these investigations, we note down two or three items of a comforting character:

1. It should be possible to reduce distortion by redesigning the cast iron cylinder and head.
2. It should be possible to eliminate the troubles arising from the failure of inefficient sparking plugs to withstand high temperatures.
3. Aluminium pistons and cylinders should help in conducting away heat from the combustion chamber: and this will alleviate annoying carbonisation troubles.

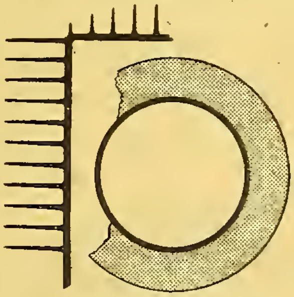

Fig. 6.—Sections of accurately-machined steel cylinders.

4. It should be possible to conduct cooling draughts over that face of the cylinder which is remote from the draught.

The diagrams illustrate in outline the kind of way in which these points might be attained.

Fig. 5 shows the plan of a streamline radiating fin. This would be no more efficient than existing types, except when the draught was head-on. As a rule, the draught is along the centre line of the machine: and in this instance the rear of the cylinder would be cooled.

The Steel Cylinder.

Fig. 6 shows a section of cylinder wall machined from steel, and shows that the wall can be of even thickness throughout. This type of cylinder has already been applied to a spring frame, four-speeded machine—the A.B.C.

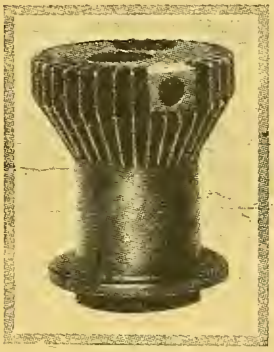

Fig. 8.—The steel cylinder, as fitted to the A.B.C. flat twin engine.

Fig. 7 is the plan of a detachable cylinder head, free from any warping side pockets. Two small exhaust valves are placed in the front or best-cooled area of the head: one (larger) inlet valve is located in the rear, or hotter area: the result would be that the fore and after temperatures would be normalised. All three valves could be operated from a cam gear placed at either side of the engine, in front, or at the rear, as the designer might prefer. The cross-section of the cylinder, with these overhead valves, would be circular from its base to its head, and no lob-sided wrenching effect would be present. No valve fractures would be experienced, provided suitable steels were employed, as aero engine practice has amply proved.

Machining the Combustion Head.

The combustion head, like the cylinder, could be machined inside and out. The valve pockets would be bolted to it.

These alterations are not radical. Radical changes were never necessary. The experience of millions of miles of touring, added to the records of Brooklands and the Isle of Man, prove that the pre-war motor cycle engine came within a very short distance of success. A few petty-looking improvements, designed to reduce warping, and to ensure an even temperature, would eliminate "konking" (the writer already possesses an engine which never "konks" or pre-ignites), and would exert a marvellous influence on the allied problems of lubrication and the sparking plug.

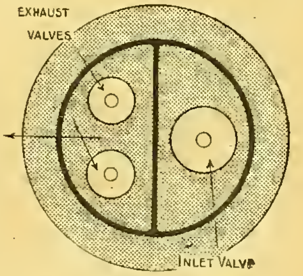

Fig. 7.—Plan of cylinder head (detachable), as described in text.

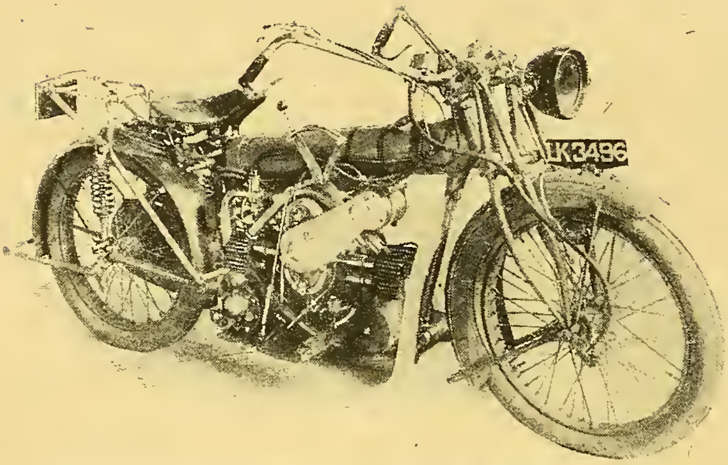
GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

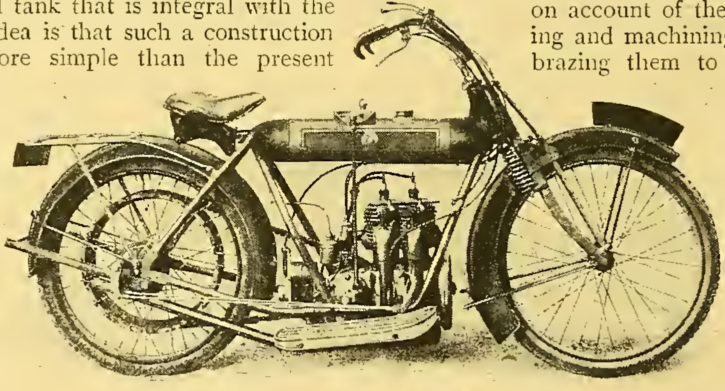
FRAMES EMBODYING THE TANKS.

A Method of Frame Construction not in General Favour, but possessing Several Commendable Features.



6 h.p. flat twin Matchless. One of the most recent designs of motor cycles. This machine possesses, among other unique features, a tubular tank as part of the frame, and in this particular case the system undoubtedly has advantages.

ALMOST every motor cyclist in detailing his ideal motor cycle or making a prophecy concerning the machine of the future includes in his specification a petrol tank that is integral with the frame. Generally the idea is that such a construction would be not only more simple than the present practice of attaching a separate tank to the frame tubes, but would render the cleaning operations much easier. Frequently it is claimed that a combined tank and frame is cheaper also, and sometimes surprise is expressed that more manufacturers have not given the idea more consideration.



A 1915 Premier two-stroke, utilising a large tube as the tank.

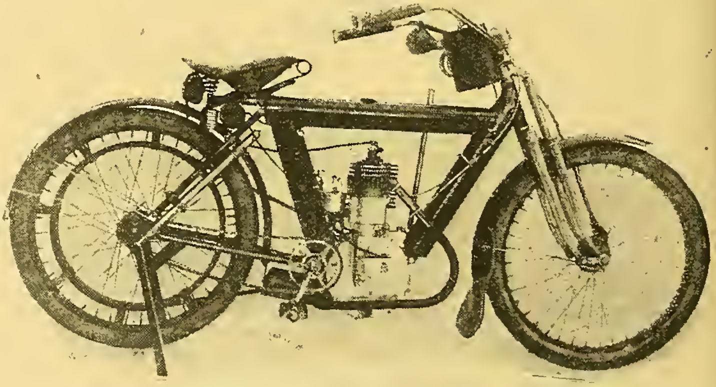
So far back as 1903 the frame tubes were used to carry the liquid fuel. This machine is illustrated on the following page, but even with the light consumption of the smallest modern lightweight one cannot imagine that sufficient fuel could be so carried to satisfy the present-day requirements, although, in normal times, petrol is obtainable every few miles.

Two American developments of this idea are also illustrated, but to the English mind they would appear to be straining the point, and not likely to be considered seriously on this side of the Atlantic. It may be remembered by some of the older readers of *The Motor Cycle* that in the Werner front-driven machine the mixture was taken from the surface carburetter in the tank through the head of the machine to the induction pipe of the engine, but since those days it has been the practice to keep the different units entirely separate, with the result that a modern motor cycle has almost as many parts as a car, but, unlike the car, every part is visible, and the novice on looking over a machine before he has decided to join the ranks of motor cyclists is struck by the apparent complication in comparison with a car number.

Probably it has been with a view to giving a machine a cleaner and simpler appearance that makers have experimented with tanks which are integral with the frames. In England the only adaptation of this general idea has been on recently designed machines, *i.e.*, the Matchless flat twin and the Premier two-stroke, in both of which the top tubes only have been used, and these have been enlarged to provide the necessary capacity.

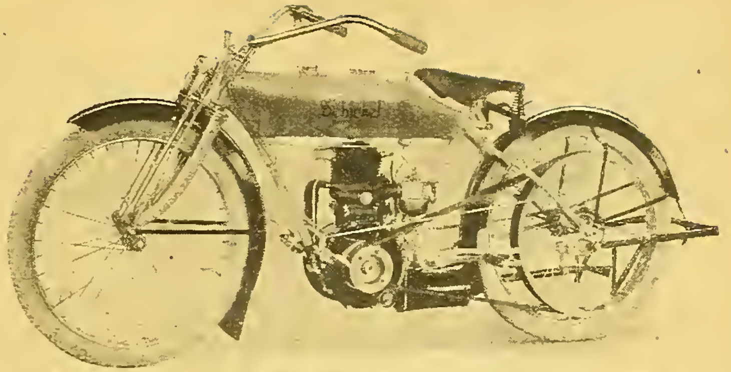
It is questionable, however, whether this form of construction will become very popular, as there appear to be very few manufacturing advantages. The total cost of such a frame is said to exceed that of a separate conventional frame and sheet metal tank on account of the greater expense of casting and machining the two end pieces and brazing them to the connecting tube of large diameter.

There is also a certain prejudice to be overcome. Designers appear to be of the opinion that any damage to the tank necessitates a new frame, while such small repairs as leakages would be inconvenient to undertake, as, instead of being able to detach the tank for transit to the makers or a neighbouring tinsmith, the complete machine would have to be sent, or the machine dismantled to enable the frame to be sent away.



A recent American design, the Osborne, in which the tubes of the frame are utilised for the carrying of petrol and oil.

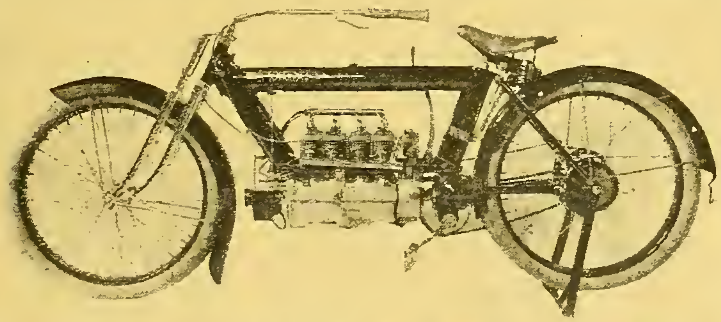
rames Embodying the Tanks.—



The Schickel tank of cast aluminium, to which the tubes are connected by means of sockets and clips.

Probably many of these prejudices are not ustified. For one reason, a tubular tank built is part of the frame is very strong, and a blow uch as will dent and burst a sheet metal tank would have no ill effect on such a tank as the Matchless, while any accident which did damage to an integral tank would, in any case, result in damage to the frame in whatever form t was constructed.

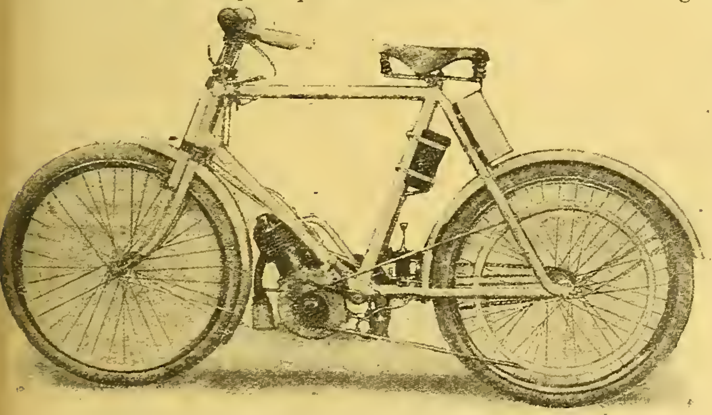
It is not unreasonable to suppose, however, hat the motor cycle of the future may embody ank and frame construction which has not yet been tried. Probably the sheet metal tank, as it is known to-day, will disappear, and in its place we may see the top part of the frame combining a tank stamped out of a single sheet of steel and welded together. I am told by the works' manager of a large Midland concern that, provided a manufacturer was prepared to concentrate upon one model to be produced in large quantities, such a method would be cheaper, stronger, and better-looking than anything yet attempted by British motor cycle makers. The war has taught several manufacturers many things connected with steel pressings, and welded units very much larger than a combined tank and frame are now being produced by men who, before the war, considered such work impossible.



The Pierce, one of the first of the American designs to use the tubes for carrying fuel.

The possibilities of pressed steel are well illustrated by the design of the Taunton light car—a British-designed proposition produced, just before the war, in Belgium. In this car the frame was one pressing, and embodied the bottom halves of the crank case and gear box. I believe, however, that at the time the Huns overran Belgium certain changes were about to be made because it was found that distortion took place and caused friction.

The engine and gear box of a motor cycle are a very different proposition from that of a car with 9ft. wheelbase, and it is quite possible that what caused distortion in a car frame would not do so on a motor cycle. It is easy to imagine two units of steel pressings, the top portion embodying the tank, head, and saddle fixings, and another combining the lower halves of the engine-gear unit; the connecting members we know now as the front frame tube and the "seat tube," the connections for the rear stays and supports for the rear springs, for such an ultra-modern frame would not be complete unless it were sprung.



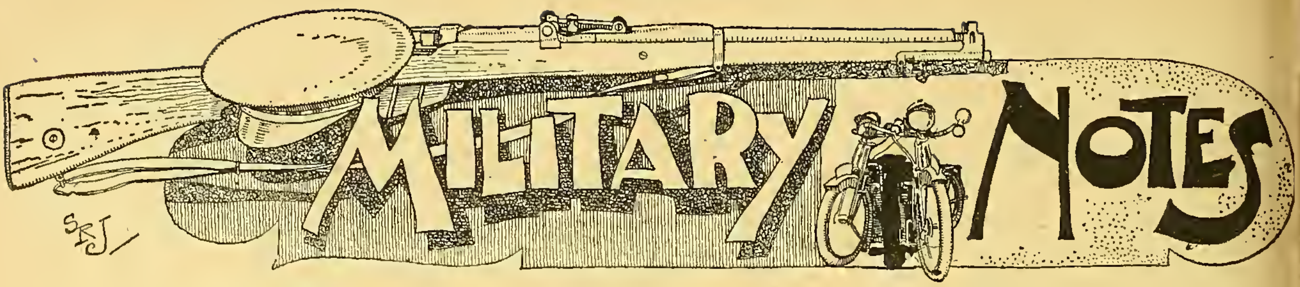
A 1903 British design on similar lines to the Osborne.

Such a machine would not appear to be so unorthodox as some of the designs suggested by pseudo-designers of "ideal" machines. This point of orthodoxy is important, as probably no people are so difficult to wean from the conventional as the British, who would be inclined to avoid such features as channel and U-sectioned framework. In appearance the machine built up as outlined would not depart very considerably from present-day designs: it would be in method rather than in appearance that the difference would lie.

For several years the Schickel American two-stroke motor cycle has had the top part of the frame, embodying the tank, cast in aluminium in one piece. The difficulty with this form of construction hitherto has been in forming a sound joint between the steel tubes and the aluminium sockets; but the increased knowledge of aluminium alloys and methods of working them derived from war work may be the means of overcoming these difficulties, although with aluminium at its present price—and we are told it will remain high for many years to come—the chances of its being used extensively in frame design would appear remote.

Extremists will tell us that in the motor cycle of the future such materials as reinforced concrete and *papier mâché* are not outside the range of possibility for tank construction—two extremes hardly promising of realisation.

VEDETTE.



Running the Gauntlet. Reminiscences from Salonica.

MENTIONED IN DESPATCHES.

WE are very glad to see the name of Col. A. E. Davidson, D.S.O., R.E., a vice-president of the A.C.U., in a list of officers mentioned in despatches by Field-Marshal Sir Douglas Haig.

MOTOR CYCLES IN SALONICA.

SOME idea of the conditions prevailing in Salonica in February of this year, and again in the early part of April, may be gathered from the accompanying photographs which have reached us from a Corporal, R.E. He writes home: "These snaps will give you ocular proof of some statements I made. I will leave it to you to imagine what it is like going through these roads in the dark with the rain pouring down in torrents, miles and miles of mud ahead, and the uncertainty as to whether one's magneto will stick it."

NEWS FROM AN OLD READER.

WE were pleased to hear from Cpl. C. T. Ringham, R.E., the other day, who, before the war, was one of the motor cycle experts of the Service Co., Ltd. He writes: "I was glad to see your paragraph in *The Motor Cycle* concerning my old business colleague, Sapper Flint. I had lost touch with him for over a year, and am glad to see he is, like myself, in England. I have just had four months in hospital, having been invalided home after the Cambrai 'do.' As a brigade D.R. I hardly had what you would call a "cushy" time there, and when my Triumph was riddled with shrapnel I was turned out with the neighbouring brigade D.R.'s to help the infantry. I get the 'Blue 'Un' all right, although a bit irregularly, and always look forward to it."

RUNNING THE GAUNTLET.

THE Distinguished Conduct Medal has been awarded to Cpl. H. Davy, D.R., R.E. The *Gazette* says that when the enemy entered a village Davy volunteered to try and get through with an urgent message. He rushed through the enemy who were holding the cross roads, although machine guns were turned on him. He was then chased down the road by two enemy aeroplanes, but got away on his motor cycle and delivered his message.

OLD-TIME REMINISCENCES.

WE recently had an interesting letter from Tom Woodman, who is now in the R.A.F. serving in Salonica. He was recently bet by a fellow motor cyclist, who should have known better, that the F.N. factory had never turned out a 3½ h.p. engine. We were, fortunately, able to help Woodman to win this bet, by sending him documentary evidence to prove that he was right.

Woodman is an old-time motor cyclist who rode in a good many of the important competitions in the early days, and some of his reminiscences are quite interesting. He writes: "It is really remarkable how little is known of the early days of motoring, yet from what on has to listen to at times it woul appear that some of the fellows would b anything from two to ten years of ag when they owned their first 5-6 h.p. two cylinder Vindec, N.S.U., or other mak of machine. A man who is twenty-tw years of age would try to convince m that he had owned one of the first Bats Others must have been enthusiasti owners of motor cycles at any tim between 1875 and 1885. If you will loo up your records you will find that I wa one of the triple winners of the Stock trophy in 1905. The same year I did th London-Edinburgh on a 3½ h.p. Vindec The six days trials of that year I wen through on a 2¾ h.p. Vindec, also winnin the appearance prize. In 1906 I was o a 5-6 h.p. Vindec, and in 1907 I had really special 3½ h.p. Vindec with automatic inlet valves, which was really th King of the Road for all-round satisfaction in the way of speed and reliability Billy Wells will remember the machin quite well. The engine was a Peugeo and had the 5 h.p. flywheels and cran case. As regards earlier history, I rod a 1¼ h.p. De Dion tricycle in 1900, an the same year I met Tessier at som sports at Blankney, Lincs., and he wa on what was then called a 1¼ h.p Werner. I remember it quite well as I owned one a bit later. It ha tube ignition, petrol in the fron mudguard, which one had to blow u with a cycle pump to force the petro to the fire-box. A match was the used on the fire-box, and one hope that the jet would not becom blocked."

Despatch riders in Salonica during the winter time have "road" conditions to contend with of a nature little realised by some people. The picture on the right tells its own story.

EASY STARTING

OF THE

ARIEL

MOTOR CYCLE

The easy starting of the Ariel is specially mentioned in nearly every letter we receive from owners. The following are a few extracts selected at random.

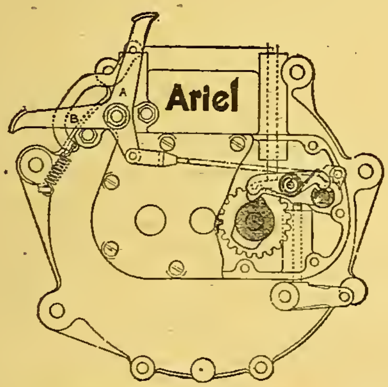
"Even on to-day's so-called petrol, mine starts at first kick."—W. D. W., Redbourne.

"The other night the bike was left out from 12 a.m. till 8 a.m. in a perfect rain storm. When I got to her in the morning she started up with the first kick."—
Dr. G. H., Shetland.

"It is easy starting and most powerful on hills."—B. S. W., Stowmarket.

"I find the easy starting a great comfort."
—Dr. D. M. H., Bolton.

"The easy starting decompressor is a revelation."—A. B., Ulverston.



The Ariel (Patent) Decompressor.

A simple mechanical device—absolutely positive in action—nothing to get out of order. To bring the decompressor into operation the front lever (A) is placed in the forward position, and the rear lever (B) pressed down to bring the engine under full compression.

Art Catalogue post free from—

The Survival of the Fittest

NATURE'S scheme does not allow for the inefficient. The weakest go to the wall. It is only Quality that counts. Quality of muscle, bone, and brain.

Similarly, the great world of Commerce has no use for poor quality. Only the best is wanted. Others may endure for a time, but the "real thing" inevitably triumphs.

Wood-Milne Motor Cycle Tyres

have forced their way to the front by sheer merit. The Quality of "Strength" is there, and the Quality of "Brain" behind their manufacture.

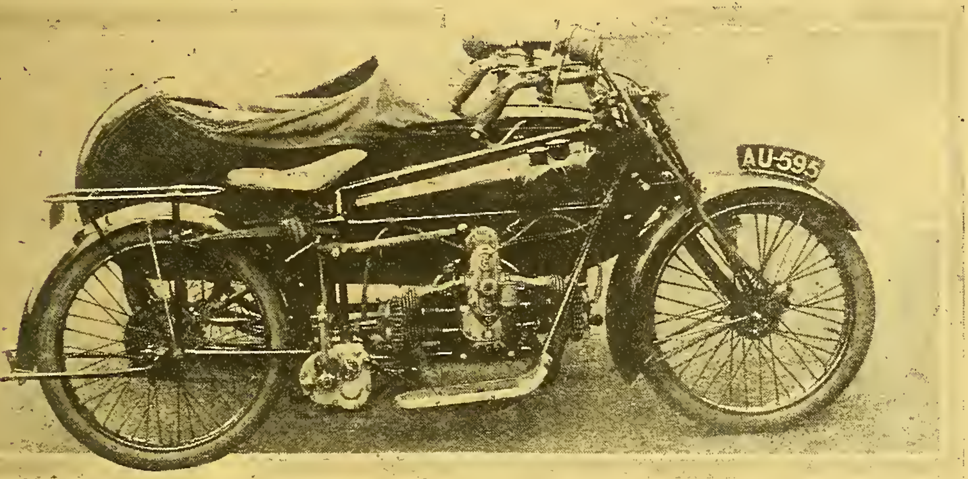
THE POST-WAR RALEIGH MOTOR CYCLE.

A Double-purpose Flat Twin of 654 c.c. Three-speed Gear and Rear Springing.



Side view of the first model of the Raleigh twin, which has been running on the road for some time past. Note the double tube frame and laminated rear springing, general neat appearance, and good lines, which are further improved in the later models.

AS we owned a Raleigh motor cycle upwards of twelve years ago, and rode it with very great satisfaction, t was with the expectation of seeing omething unusually good that we ourneyed to Nottingham last week to nspect the preliminary model of the ost-war Raleigh, and we were not disppointed. Let us say by way of preface hat we are heartily glad to welcome his well-known firm back again into he ranks of motor cycle makers.

The space at our disposal is not suffiient to do full justice to this interesting machine (which has been designed hroughout by Mr. William Comery, hief engineer and works manager of the Raleigh Co.) in the present issue, but we hope to refer to it again shortly. The preliminary model has been on the road ince April, 1917, so it has had a very horough testing, and has acquitted itself n a most satisfactory manner.

The Engine.

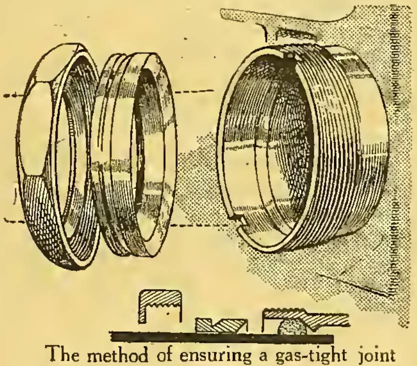
Naturally, our detailed description commences with the power unit. This takes the form of a flat twin of 77 mm. bore × 70 mm. stroke—decidedly a short stroke engine, a form of construction which seems particularly desirable in the case of a flat twin—a type of engine which is by nature rather lengthy. The present engine has a solid crankshaft, over which the roller bearing big ends are threaded, but a built-up shaft of very special design—a beautiful piece of work which we are not now at liberty to describe in detail—has been produced for subsequent machines. We do not think that we are betraying any confidence by saying that the construction is such that when the first model was assembled by hand and tested in a lathe it was found to be absolutely true. It is provided, moreover, with very adequate balance weights, with the object of overcoming the unbalanced couple which is present in every flat twin having a two-throw crankshaft.

The gudgeon pins are secured in the connecting rods, and rock in bushes fitted to the pistons, which are provided with two rings and an oil groove.

Lubrication.

The engine is supplied with oil by means of a drip feed, though it is likely that this will be superseded later on by a mechanical system, which will supply the proper proportion of oil to every part without relying upon splash or oil fog in the crank case. To ensure the front cylinder getting its proper supply of oil—always a consideration both in flat and V twins—the crank case is divided by means of a web, and the oil fed into that side in which the big end of the front cylinder dips; thence it overflows to the other side, and supplies the rear cylinder. Thus the front cylinder gets the first call on any oil in the crank case. Experiments in drilling this web, however, have shown that the lubrication is remarkably equal in the Raleigh engine, even when an equal level is allowed on each side.

An unusual feature of the Raleigh engine, which has already been referred to in the pages of *The Motor Cycle,* is that the carburetter is bolted directly on to the timing case cover, and the mixture is thus warmed at the beginning of its entry into the engine. Moreover, the crank case release valve is made by cutting ports in the pinion which drives the magneto; the ports open at the proper intervals and allow the warm air from the crank case to pass around the induction pipe with excellent results, and the air being taken into the engine cold is not expanded prior to its entry; thus the engine gets a fuller charge than would otherwise be the case.



The method of ensuring a gas-tight joint at the inlet pipe connections. The pipe is plain and has no flanges, and the ring of asbestos string is gripped tightly between two sloping surfaces and effectively seals the joint.

The Induction System.

Where the inlet pipe leaves the timing case the gas-tight joint is made by means of asbestos string and a brass gland secured by a lock-nut; this admits of expansion by heat without the joint being affected. Easy removal of the gland is attained by slotting the ends of the stub pipes and turning a groove in the gland, by means of which it can be taken out with a small tool or the point of a nail. The exhaust pipe is flanged and held in place by a detachable wire and lock-nut.

The valves are side by side and work parallel to the cylinder bore. Each valve is fitted with two springs—a method which allows less spring tension and at the same time no bouncing or chatter of valves, owing to the periodic vibration of the two springs being different.

The sparking plugs in the experimental engine are fitted into the inlet valve caps, but in the later models will be placed at an angle between the valves. This will enable the valve caps to be interchangeable. A plug has never been known to burn out on this engine.

Both inlet and exhaust ports are nicely curved to ensure an easy flow of gases.

The cylinders, which have detachable heads, are held in place by long bolts, one on each side, and a bridge piece. The bolts are hinged where they join the crank case. Thus when one nut is loosened they can be folded in either direction, for the bridge piece is slotted at one side, and the cylinder removed.

The Post-war Raleigh Motor Cycle.—
The bridge piece has a steel ball in its centre, which bears upon the centre of the cylinder and holds the whole in position with a perfectly even pressure. This arrangement makes the quick removal of the cylinders a very easy matter, the nuts being readily accessible.

A shock absorber is provided on the engine-shaft, the details of which are not yet available. In future models the sprocket will be outside the 12in. flywheel. This simplifies the fitting of a chain cover and makes the engine very compact. The experimental engine has an extra stay from the crank case to one of the tubes below the tank.

The Spring Frame.

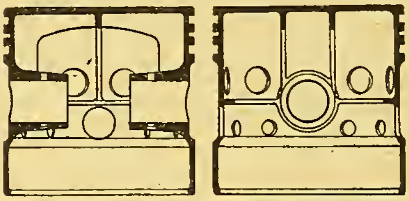
The frame is of double straight tubes throughout, with the single exception of the tube above the tank, which slopes downwards from the head to the seat-pillar. The rear springing is most effectively carried out by means of laminated springs attached to lugs which are extensions of the twin tubes running from the front of the frame. The carrier is not sprung, but the toolbox will be carried on the sprung part of the frame below the rear part of the tank. The front forks are the latest pattern Brampton, designed to meet vertical and horizontal shocks. The down tubes spread out from the head and straddle the front cylinder.

Wide mudguards are fitted, the forks passing through the front mudguards. The holes through which they pass are, however, entirely covered with adequate mud traps. An important point—one, moreover, often neglected.

The head lug is reinforced from top to bottom; a lubricator is provided halfway up for the injection of grease, and the upper ball caps are made to overlap the lower with the object of keeping all dust and dirt out of the bearings.

Detachable Wheels.

Not only are the wheels detachable from the frame, but the hubs are themselves detachable from the wheels in a very simple and effective manner. The removal of the central bolt allows the hub to be unscrewed from the driving and brake mechanism, which in the case of the rear wheel remains *in situ*. When in position the driving mechanism is very firmly attached to the wheel by means of screwed-up cones, and further is prevented from revolving separately by pegs. This method obviates any possibility of backlash, so destructive to tyres, transmission, and engine.



Two sections of the Raleigh piston. There are two rings at the top with an oil groove between, three cross webs inside the head, and the skirt drilled to assist lubrication and reduce weight.

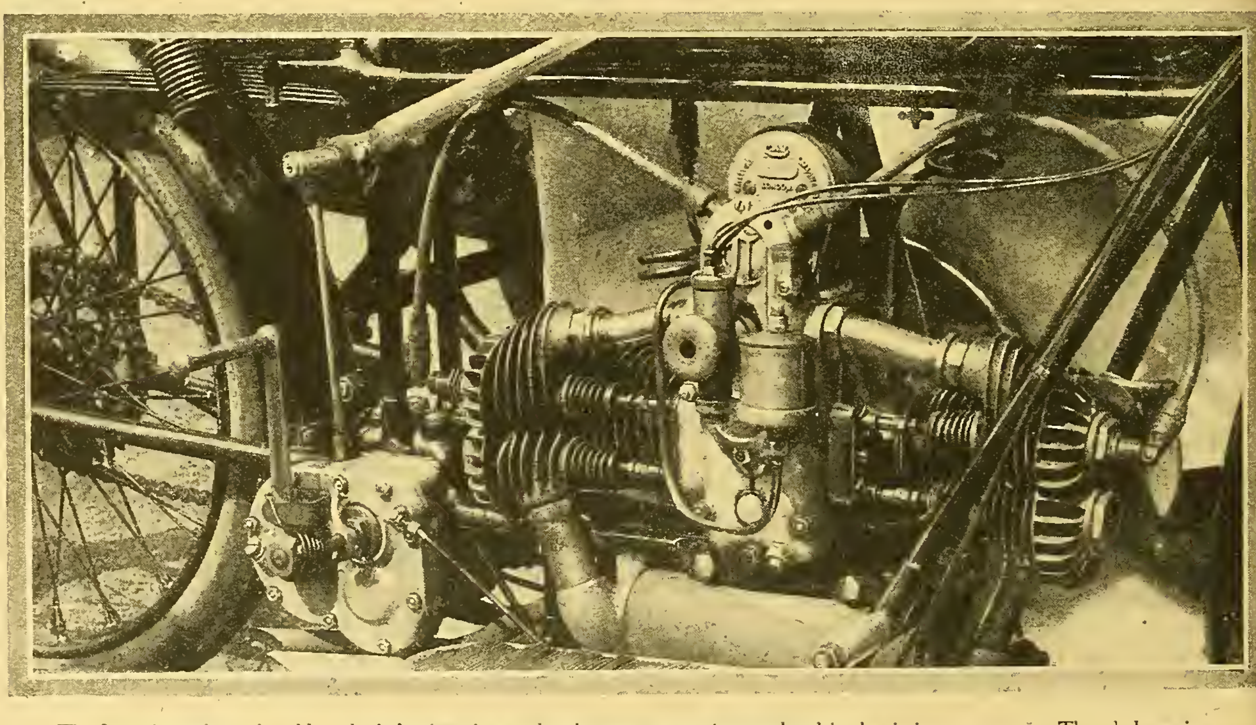
The rear brake is an expanding drum operated by the left heel. The front brake works inside the V of a dummy belt rim spoked to the hub, and removable in the manner just described, though the front wheel can be taken out with the brake rim in position if so desired. The hubs have large ball races and are very adequately protected from dirt, and the outside dust caps used as a means of locking the mechanism when screwed up. Lubrication is supplied by a grease gun through the hollow cent bolt—a much more convenient meth than an oil cup between the spokes.

Transmission.

The engine power is transmitted to t Sturmey-Archer three-speed gear box the countershaft, and thence to the re wheel by chains. The clutch is op ated from the handle-bar, but may arranged for a combined hand and fo control. The gear lever is convenient placed for the right hand, the controlli springs being on the lever instead of the gear box—a position which remov them farther from the deleterious effec of mud. On the later models the lev will be provided with a gate on the si of the tank, so arranged that it will possible to change instantaneously eith up or down to middle in the dark.

The tank tapers from front to rea and is of very sensible dimensions; lar filler caps are fitted. Other items a C.A.V. magneto, Amac carburetter, ar Dunlop (650×65 mm.) grooved tyre The ribs of the rear wheel tyre are ju worn off in 4.000 miles running, almo entirely with a heavy sidecar attache but the other tyres show very slig signs of wear—a result which speaks we for the transmission. Petrol consum tion is said to be about 80 m.p.g. so and 70 m.p.g. with sidecar. The weig of the complete machine, viz., 240 with a full tank, speedometer, etc., com pares favourably with that of oth machines of similar or even less powe and the machine, having a high clea ance and spring frame, should prove ve suitable for use Overseas.

We are asked to mention that the pri has not yet been fixed, nor can delive dates be quoted. Intending purchasers—and, doubtless, there will be many—mu therefore possess their souls in patience.



The flat twin engine unit. Note the induction pipes and carburetter connections enclosed in the timing case cover. The whole engine unit has a forward or backward movement for adjusting the driving chain, the gear box being a fixture in the frame.

Motor Cycles for the U.S.A. Army.

For carrying on the war, the U.S.A. Government has purchased 3,520 passenger automobiles and 6,126 motor cycles. This will clearly show how greatly the motor cycle is valued by the army of our newest Ally.

Sidecars on War Work.

More and more motor cycles and sidecars are being pressed into service by Government Departments, but still quite a lot of high-powered cars are to be seen transporting officers about when motor sidecars could easily perform such a service with infinitely greater economy.

The American Bosch Works.

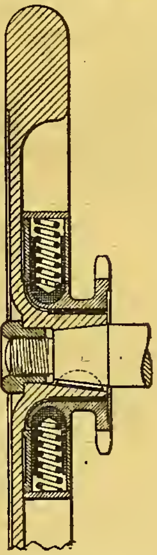
The American Government has recently seized the plant and works of the Bosch Magneto Co. as alien-owned property. According to English precedent, the works will be kept running as usual under the supervision of a Government-appointed management.

Some Output.

In view of recent remarks that have appeared in *The Motor Cycle* on the possibilities and probabilities of the English magneto trade after the war, it is of interest to know that the output of the American Bosch works is 150,000 magnetos per annum.

Raleigh Patents.

In a recent issue we gave particulars of two important patents granted to the Raleigh Co. These were for a flat twin engine and a four-speed gear box, which revealed the fact that the famous cycle concern was again interested in motor cycles. In this issue we are able to give a description of the completed Raleigh machine, while on this page we print two other inventions patented by this company.



Cross section of the Raleigh patent shock absorber and flywheel.

War-time Measures.

Our trade contemporary, *Bicycling News*—incidentally, the oldest cycling paper in the world—is now issued in a convenient pocket form, about 11in. × 4in., as a temporary war economy measure.

The Suggested Black List of Motorists.

What do readers think of this ridiculous scheme, recently criticised in *The Autocar?* One of the most delightful jokes of the war, it is worth reading about, and we much regret that at present we have no space to devote to the ludicrous.

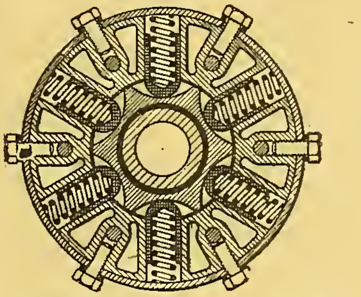
The R.O. and the M.C.

A recruit recently went before various recruiting officers in order to join as motor mechanic in the R.A.F.—a branch for which he was well qualified as an experienced man. He was finally referred to the head recruiting office in a large Northern town, some twenty miles from his home, and the officer-in-charge recommended him to apply to *The Motor Cycle.* The man has visited all told some four recruiting offices, separated on an average twenty miles apart, and he finished up in the infantry.

The Luxury Tax.

The Select Committee on Luxury Duty has received from the Automobile Association a vigorous protest concerning the proposed taxation of motor vehicles as luxuries. It is contended that vehicles used for national, business, or other urgent purposes cannot be regarded as luxuries. Luxury motoring does not exist, and a tax on motor cycles or cars would cause unmerited hardship and a considerable increase in the already heavy burden of taxation borne by motorists.

The Automobile Association has been informed that the views embodied in the protest will be placed before the Select Committee when they consider the application of the duty to motor vehicles.



The shock absorber patented by the Raleigh Co., embodying spring-loaded plungers in concave recesses.

Special Features.

THE POST-WAR RALEIGH FLAT TWIN.

AIR-COOLING.

FRAMES EMBODYING THE TANK.

Oil in Egypt.

According to a reply to a recent question in the House, it would appear that the development of oil fields in Egypt is proceeding satisfactorily. At present the work is in the hands of a private company working under Government approval and assistance.

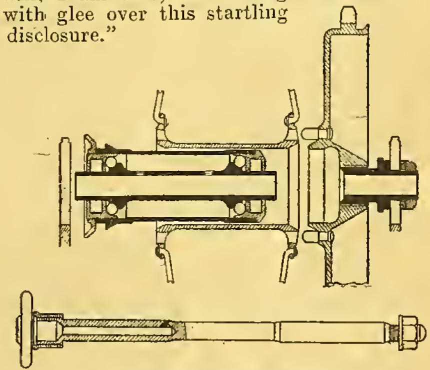
From Passenger Work to Solo Riding.

We have recently had a long spell on a solo 'bus, after some years of passenger machine work. To our mind, the most noticeable feature of the single-tracker is its marked economy. The belt, which fell off in protest the other day, resembled a piece of rope; the canvas was everywhere exposed and in two places was practically broken through. In this condition it had given 2,000 miles of service and undoubtedly it would not have stood up to fifty miles of sidecar work. Moreover, tyres seem to possess everlasting wear.

The Doom of the Single Cylinder.

An R.A.F. sergeant sends us a cutting from one of the cheap illustrated dailies. The paragraph reads as follows: "A big two-cylinder Gotha raider got into difficulties, and sent out rockets and signals. Eventually the machine crashed in a field about four miles away. Six bombs were dropped in the field, doing no damage."

"After this latest achievement in German aeroplane engine manufacture," writes the sergeant, "there is no doubt that the single-cylinder will soon become obsolete. The twin-cylinder enthusiasts will, I am sure, be rubbing their hands with glee over this startling disclosure."



The Raleigh patent detachable wheel which, in some respects, is reminiscent of car practice.

Control of Horse Transport.

Horses have long been rationed, and now their services are being officially controlled. Moreover, not only is the purchase of horses coming under official supervision, but so is their *sale*.

Among the Classics.

A reader recently came across a list of second-hand books, in which "Motor Cycles and How to Manage Them" (published from these offices) was sandwiched between "Pilgrim's Progress" and "Gulliver's Travels."

Cams.

It is said that G. E. Stanley carried his racing cams in his waistcoat pocket. The camshaft of a modern aeroplane engine is somewhat larger—in fact, several feet long—and no man would care to carry it far, even across his shoulder.

Our Contemporaries.

The *Scottish Cyclist and Motor Cyclist*, which enjoyed a considerable popularity this side the Tweed, has been absorbed into its parent journal *The Motor World* as a war economy measure, *i.e.*, in paper-saving.

Another contemporary, *Bicycling News*, which is entirely a trade paper, has adopted a novel shape as a means to economy. Normally this paper is about the same size as *The Motor Cycle;* now the size of its front cover is reduced by about half, the division being made along a vertical line!

Airmen Motor Cyclists.

It is interesting to note that the following famous American airmen graduated as motor cyclists: The Wright Brothers, Glenn Curtis (who first gained prominence as a motor cycle racing man), Lincoln Beachey, Glenn L. Martin, and Art Smith.

On the application form for enlistment into any branch of the United States Aero Service the following questions appear: "Are you a motor cyclist? Do you understand the care, operation, and repair of motor cycles and motor cycle motors?" The questions asked clearly indicate that the Government consider that motor cycle-trained applicants are specially qualified for the Aero Service.

Scenes of Yore and Roads of To-day.

On a hurried scamper back to Town from a Kentish aerodrome the other day we passed through some country happily familiar in pre-war days. The rolling green hills still smile, and the fields are ablaze with wild flowers, though we are not there to look at them. The roads are given utterly over to the casual drover and his somnambulistic horse. When peace comes we shall have to teach him the rule of the road all over again! Near Oxted we met a young officer on a 3 h.p. Enfield unashamedly sporting a demure damsel on the carrier! We raised a shocked hand, in the manner of Mr. George Robey, and he grinned back at us. After that we "encountered" (the word is used advisedly) the Caterham Road, and what that highway has left of our machine we mean to go over shortly for lost nuts. It would require the vocabulary of a Capt. Kettle to do justice to such surface!

A Solution of the Petrol Difficulty?

A member of our staff says he has found it at last—the four-legged remedy, he calls it. He may be seen most evenings trotting round the lanes of the village in which he lives, but if you talk to him he says pathetically, "Well, I must get out somehow, but what *are* we coming to?"

An Excuse for Riding.

Readers who are not members of the "National Motor Cyclists' Fuel Union," but would like to use their machines all the same, might well consider the wisdom of offering their services to the local Volunteer Force. These organisations are often in need of transport to ranges and manœuvring grounds, and offers of help are generally welcomed.

A Gordon-Bennett Story.

To the late Mr. Gordon-Bennett's achievements must be added that of being one of the first to get the full measure of the Kaiser, and to announce publicly this measure not only to the world at large, but also to the prize Hun himself. Twenty years ago Mr. Bennett refused the Kaiser's invitation to dinner, and also the support of the *New York Herald*, and he followed this rebuff by proclaiming the Kaiser "a permanent menace to the peace of Europe."

Motor Cycling Footwear.

When will somebody design us a really waterproof boot? At this season of the year one may run into some very nasty little storms; but who wants to be encumbered with Hutchinsons? Water creeps into the laceholes, the thin leather of the tongue is soon sodden, you feel an oozing round your toes, and the next stage is quinine and eucalyptus! Surely it would be possible to design some kind of foot gear which, if kept decently dubbined, would afford adequate protection. Why not borrow a tip from our womenfolk, and have the laces running up the side?

What caused the Fire?

A 1916 Indian, owned by a Lee, S.E., ex-soldier, was almost destroyed by fire in the Old Kent Road the other afternoon, owing, it is said, to the petrol overflowing from the filler cap and running down the rider's coat, shorting the plug. Why shorting the plug should cause a conflagration it is difficult to say. The owner escaped injury.

Of Interest to Motor Cyclist Photographers.

Our publishers, Messrs. Iliffe and Sons Ltd., have acquired *The Amateur Photographer and Photographic News* and other photographic publications of Messrs. Hazell, Watson, and Viney, Ltd. During the war it is proposed to publish *The Amateur Photographer and Photographic News* with Messrs. Iliffes' other photographic paper, *Photography and Focus*, the combined journal embodying the leading characteristics of both publications.

Imports and Exports.

The value of imports of motor cycles, parts, and accessories for the month of April amounted to £6,228.

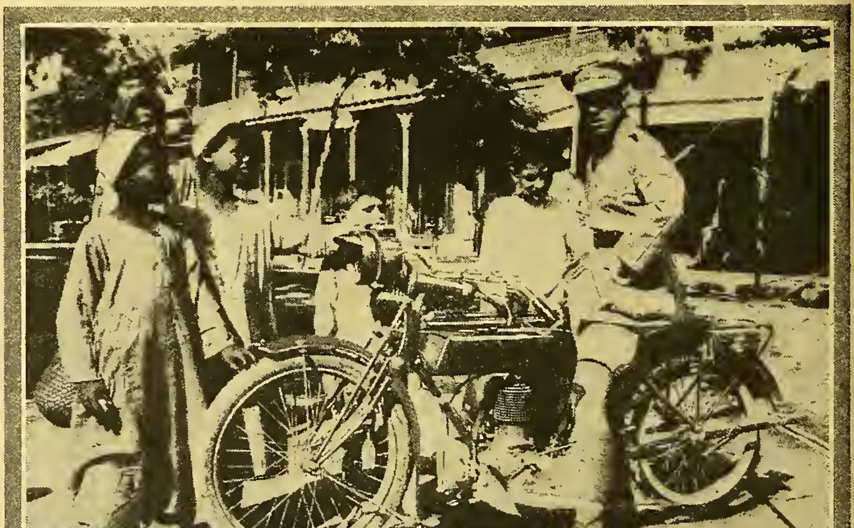
April Exports.

Compared with March, last month's exports showed an increase of £30,000. Against the figures for April, 1916, however, there is a decline of nearly £10,000.

	1916	1917	1918
Number of machines ..	626	984	559
Value of motor cycles, parts, etc.	£53,592	£72,824	£63,117

Magnetic Ignition.

In reporting particulars of the American Liberty motor cycle, *The Motor Age* (U.S.A.) refers to its "magnetic" ignition in both heading and context. In quoting the article for advertising purposes, the Bosch Co. of America draw a ring around "magnetic," and add "means magneto." Is the magneto disappearing so quickly over there that the motoring press have forgotten it, or has the war robbed the paper of its motoring staff?



A little group in Port Said. Interested native children around a D.R. astride a W.D. Triumph.

THE MOTOR CYCLE AVIATION SECTION

The enormous importance of the Air Service needs no emphasis; it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National Service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouragement of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

Castor Oil.

Now that the American aeroplanes are eckoned to be using 50,000 gallons of astor oil a day, perhaps Young Hopeful will be spared hearing mother say, "Now hut your eyes, dear, while mother gives you something to do you good!" Is there any section of the community that has not ome sympathetic interest in the aeroplane?

◇

Early Designs and their Origin.

Many of the early aeroplane designers ought inspiration from nature, often with disastrous effects. In 1897 Clement Ader designed a machine shaped startingly like a bat, the vanes of the propeller being, in fact, made of feathers. This craft did an elongated hop in the course of a military trial. (Ader, by the way, who was born out of his time, was he originator of those deadly little *léchettes*, steel arrows resembling a pencil. Dropped from 6,000 feet, these, before he advent of the steel helmet, would do deadly execution, and their light weight permitted thousands of them to be carried.)

Many of us will remember the dangerous Blériot "canard" of 1911, which flew tail first, and was indeed strongly reminiscent of a duck. The early Deperdussin machine resembled a hawk, the little 1912 Ponnier clipped-wing racer spun into the air like an infuriated bee, a resemblance heightened by its extreme compactness, and the Etrich monoplane (forerunner of the once terrible Taube), built in Austria in 1908, was copied from the zanonia leaf. At the other end of the scale was that amazing craft with circular planes, the Cedric Lee, so aptly christened "the Doughnut," which used to eddy uncertainly in the neighbourhood of Worthing, and which terminated its career in a magnificent series of unpremediated loops, the last of many vigorous attempts to kill its pilot, in which endeavour it happily failed!

A Remarkable Exploit of a Fighting Airman.

Fonck, the French airman, actually brought down six enemy aeroplanes in three hours on the 9th inst.

According to official accounts, Fonck used two machine guns arranged as a pair. It was at four o'clock in the afternoon, when on patrol, that this intrepid airman attacked a group of three enemy biplanes, of which two were fighting machines protecting an observation machine. The two fighting planes were shot down in ten seconds and crashed near Moreuil. The observation plane turned back, but its retreat was cut off five minutes later, and, the petrol tank being riddled, it fell in the same district in flames. The fight only occupied seven minutes, during which time Fonck fired about one hundred rounds.

He returned to the base, filled up with petrol and oil, and remarked that the three brought down undoubtedly belonged to the same squadron, that the commander would become anxious when they did not return, and would send out a patrol to look for them, "In which event," he said, "there is more work for me to do, and I am going up again." He gave a few orders, and at 6.30 p.m. went off with another patrol, which fell in with a biplane just over Montdidier. This was attacked and smashed up in the air. Then, while returning, he spotted two other enemy machines, and in less than five minutes nothing remained of them but two gigantic torches, which burned themselves out near to Havricourt.

His performance is equalled by the British aviator, Capt. Trollope, who, in the Somme battle on the 23rd of March, also brought down six machines, and was afterwards posted as missing. Capt. Ball is credited with five in one day; and the German airman, Von Richtofen, also accounted for five, although he paid the full penalty soon afterwards.

A Motor Cyclist Airman.

An old contributor to *The Motor Cycle*, the Rev. R. M. Bankes-Jones, who is now a lieutenant in the R.A.F., has left England for the Middle East. He writes: "I have been flying single-seated scouts for the last three months, and have been giving instruction on Avroes."

◇

Ramifications of the Aero Trade.

As an illustration of the way in which a trade can necessitate work in little-suspected directions, a statement in the *Evening Post* (N.Y.) takes some beating. It was there recently stated that one of the necessities of the aero trade was the planting of great acreages in India for the growth of the oil seed for motor lubrication!

◇

French Pilot's Deeds.

The celebrated French "Ace," Sec.-Lt. Guérin, whose squadron has just been strongly commended by the commanding officer for special services in the battle of Picardy, has been unfortunately wounded in the thigh by a machine gun bullet.

He has brought down seven enemy aeroplanes during his career, and his squadron is responsible for forty-seven aeroplanes and four balloons.

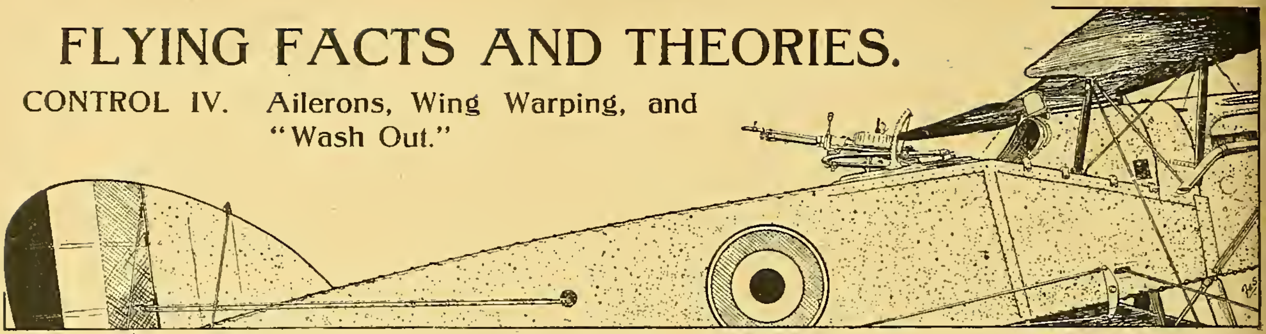
◇

Aero Ambulance.

Another interesting French novelty is the employment of a standard type of plane, with a slightly wider fuselage than usual, in which a bed is placed for a wounded passenger, who is strapped securely, and thoroughly screened by wind shields. Eighty miles an hour has been attained with these craft, which are plainly marked with the Red Cross insignia. On the face of it this might mean the saving of many a valuable life, the high speed and the absence of nerve-wracking jar being points in its favour.

FLYING FACTS AND THEORIES.

CONTROL IV. Ailerons, Wing Warping, and "Wash Out."



By W. G. ASTON, A.F.Ae.S., A.M.I.A.E.

THE object of the organs of lateral control, *i.e.*, flaps or wing-warping, is to enable the aeroplane to be rotated on its longitudinal axis so that, whenever required, it can be brought by the pilot on to an even keel, or, when turning, can be banked so as to obviate the tendency towards centrifugal side-slipping. With a stable machine there is, strictly speaking, no necessity for any lateral control, provided it be kept a reasonable altitude above the ground, as the inherent stability will automatically cause the machine to bank itself on a turn, and it will also equally automatically recover from the rolling effect of a gust. As, however, this recovery means inevitable loss of height, it is essential that the pilot have at his command means of adjusting the lateral trim of the aeroplane when near the ground. This control is also called for by variations in the engine torque, which artificially alter the loading on each wing and demand some form of adjustment in order that the machine may fly straight.

Wing Warping.

In the early days the majority of aeroplanes, especially monoplanes, were provided with a device whereby the wings could be helically "warped," that is to say, so that the angle of incidence of one tip could be increased whilst that at the other was decreased, as indicated in fig. 1, where A is the normal position of the plane, B that of one wing when warped, and C that of the other. Apart from any slight deformation of the wing section that may take place, it is clear that the only thing that varies is angle of incidence.

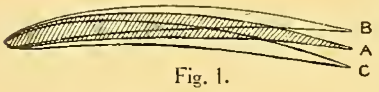


Fig. 1.

Nowadays control by means of flaps or ailerons is standard practice, and fig. 2 shows how, when these are brought into action, the effect on the whole plane section is not to produce a change of angle of incidence, but an alteration in camber. This is a preferable system in many ways. First of all, it is better from a structural point of view, since practically the whole of main planes can be made rigid; secondly, unlike the warping gear, the flaps can be "balanced" with a small part of their area projecting forward in front of the pivot, and so be made to demand less effort from the pilot in working them; and thirdly, they promote, generally, a smaller fore and aft movement of the centre of pressure, the result of which is that the wing spars can be placed closer together.

One considerable objection to wing warping is that it necessitates a deformation of the plane framework, which in turn can only take place provided there is a certain amount of "give" in the fabric. Needless to say, this is, from all other viewpoints, highly undesirable, as in the interests of lifting efficiency this fabric must be everywhere as tight as a drum.

Ailerons.

The ailerons are placed at the tips of the wings for the purpose of promoting the maximum turning effect about the fore and aft axis with the minimum effort on the part of the pilot. The smaller the angle through which they have to be moved for any given result the better, as, whether they are pulled up or down, if the angle is big, the drag of the plane as a whole is liable to be sensibly increased.

It is obvious that the effectiveness of the aileron must be considerably affected by the section of the plane which immediately precedes it, and which deflects the air in which the aileron is to work. For instance, if it is situated in the rear of a strongly-cambered section it is calculated to promote a bigger effect if it is pulled slightly "up" than if pulled slightly down, inasmuch as whereas in the former case it does not much alter the flow of air, in the latter case it alters it very materially. In order to enhance the effectiveness of ailerons, as well as for another object which will be mentioned later, it is common to find designers "washing out" the wing camber towards the wing tips; that is to say, the section is deepest at the centre and gradually flattens out towards the tips. The flatter the plane section in front of the ailerons, the more effective will they be, especially when controlled through small angles, and this is, of course, most desirable from the point of view of the pilot, who naturally desires to get the biggest effect with the smallest effort. It is not without interest to note, in passing, that in a similar way the fixed vertical fin very greatly increases the effectiveness of the rudder which is placed immediately behind it. It is as though the fixed plane acted as a guide whereby the deflecting influence of the rudder were greatly enhanced, just as when you hold an iron rod in a vice you only bend it gently if you pull on the extreme end of the rod, whereas you bend it very sharply if you pull on it close up to the vice. Now the object of

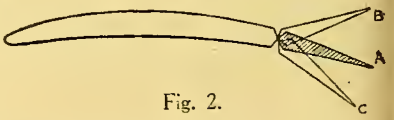

Fig. 2.

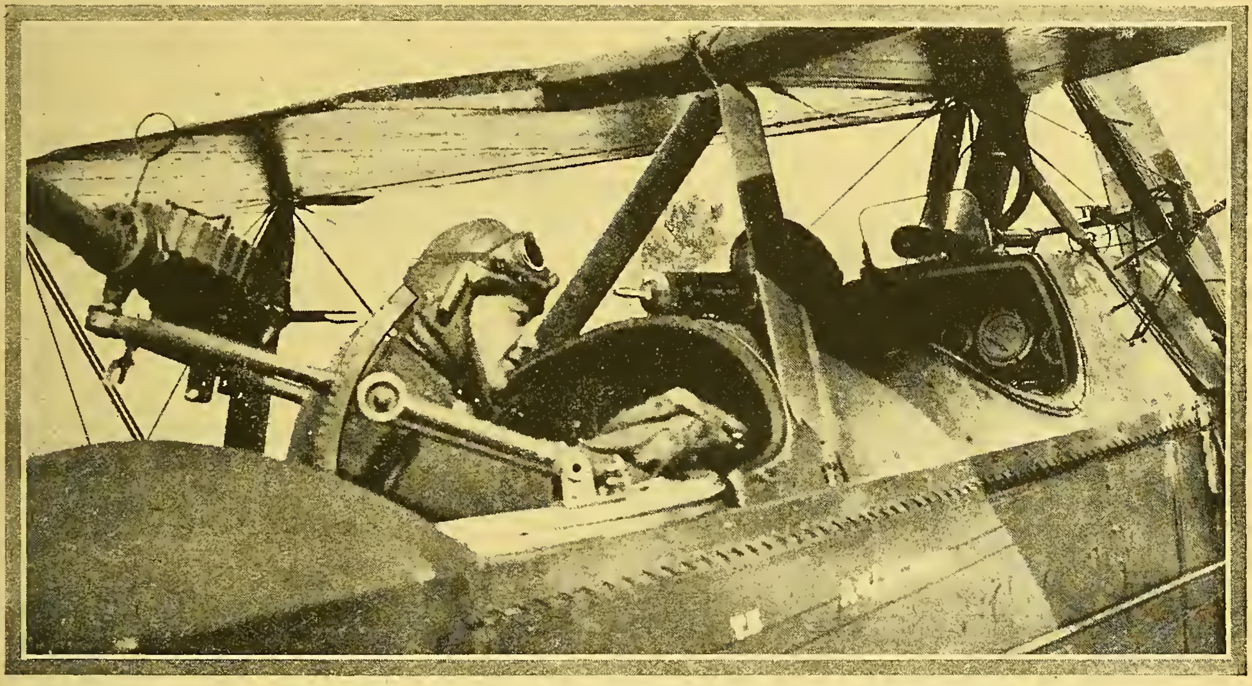
Flying Facts and Theories.—
ailerons, rudder, and elevators is to bend the air flow, and they will execute this work better, and therefore be lighter in construction and smaller in size, if they immediately follow a flat plane, or one of symmetrical curvature both top and bottom.

Variable Camber.

The idea of using flaps running from tip to tip of the main planes so that a variable camber effect could be given to the wings as a whole has been tried, but with no great measure of success. As I shall show in a later article, variable camber would be a most valuable device in widening the gap between the aeroplane's highest and lowest speeds.

In multiplanes it is not uncommon to find that the flaps are confined to the trailing edge of the top deck, though in perhaps the majority of present-day designs they are added to all the main surfaces and connected together either by rigid struts or wires. Generally speaking, the chord of the aileron is small in relation to its length, the ratio being somewhere in the neighbourhood of 1 to 6, and no object seems to be served by making it bigger.

The second advantage of the "wash out" mentioned above is this, that the maximum deflection of the air, which naturally occurs at the point of maximum angle of incidence, is surrounded by regions at which less deflection occurs, and so on until at the wing tips the deflection is very small indeed. This gradual process prevents the formation of power-wasting eddies and "surfaces of discontinuity."



An R.A.F. observer on the British Front in France with his wireless transmitter to keep in touch with our guns.

DAY AND NIGHT BOMBING.

THE average newspaper reader is encouraged to contrast the pluck of the British pilot who bombs Rhine towns in daylight with the cowardly Fritz, who only crosses the Channel by night. Nobody wishes to belittle the pluck of our pilots, and it is perfectly true that they run risks in bombing work which Fritz has never faced. But daylight bombing raids probably stand rather to the credit of the technical experts than to sheer pluck on the part of pilots. The long-distance bomber must obviously be quite differently designed for day and for night work. At night its chief protection is its invisibility: the anti-aircraft gunners will seldom sight it, even with the aid of searchlights, and defending fighter machines may hunt for it in vain. As a consequence it need neither fly high nor fast. The Gothas cannot get very high with their "eggs" on board, and their best speed is probably about 80 m.p.h. with full load. When screened by night, they are safe and formidable: but they have never ventured to come by day, since London was equipped with plenty of guns and defending scouts. If they came in broad daylight to-morrow, very few of them would reach the coast on their return journey. Hence our own daylight raids into Germany imply one of two things. Either the towns we attack are very imperfectly defended: and this is highly improbable, seeing that our bombing squadrons have to cross the front lines, traverse the aerodromes of the Hun fighter squadrons, and pass over dozens of his Archie batteries. Or else—and this seems to be the obvious explanation—we have a certain number of machines so immensely powerful that they do not rely upon invisibility for defence: they must be able to fly high and fast with their cargo of bombs on board, and must carry sufficient guns to put up a decent scrap with any scouts who try to intercept them. TORQUE.

THE EXPERIENCES OF A "HUN."

II.—Impressions of an Observer on controlling an Aeroplane for the First Time.

By "PITOT." (*Concluded from page 498.*)

First Duel.

THE sonorous roaring of the many engines early next morning rendered further slumber a remote possibility, and, with hands thrust deeply in pockets, I trudged through the dewy grass down to the sheds where the white planes glimmered in the beams of the rising sun. (N.B.—This is all rot really, the planes were a dirty brown, still——!) There was little wind; in fact, the weather was good—too good!

After kicking my heels for the usual period I shinned up into the nacelle, but this time in front of, and not behind, my instructor, who comforted me with the cheery remark that he would first do one or two circuits and then hand over the reins to me.

Keeping merely a light hand and foot on the respective controls, I felt convinced I should never be any good, when the time came, which it soon did. The machine at last sat placidly chewing the cud while the pilot prompted me for the last time; then "Now take her off," said he.

A timid paw advanced the throttle, the beast snorted and charged with a bellow from its exhaust. Tentative hands clutched the controls, and my fumbling feet pressed the rudder. *Mirabile dictu*, the bird rose slowly into the air and gradually ascended. A burst of confidence swept over the occupant of the front seat. "Well," I thought, "this isn't so bally diff——" A gloved hand waved suddenly in front of my face reminded me that even modern science had failed to produce an anti-toxin for "stalling." So I moved the "stick" hurriedly forward, and began to see-saw.

A second more vigorous wave reminded me of the fact that it was possible to turn—rapid messages from my brain made my shaking limbs perform their (more or less) correct functions, and behold! the machine lay on its side, swung its tail round behind its nose—and the first turn was *un fait accompli*.

One more hour's instruction, and I was pronounced to be ready for my "first solo."

A final "landing" was given, and the instructor clambered down to earth, leaving his pupil seated in the front and feeling, oh! *so* lonely.

"Now remember, just one circuit and land, no more," was his parting word.

Setting my teeth and placing my feet firmly on the pedals, I gave the throttle a hurried biff. The machine commenced its usual bull rush, promptly spun round, and stopped.

However, it was again placed into wind, and once more the engine roared. This time a straight course was maintained, and the machine rose.

"Now you *are* alone," was my inward comment—and I certainly felt more remote from the world than ever before, as the ground, with its hangars and huts, receded from view.

"About time you turned," was my next brain wave.

After a great screwing up of determination, the turn was accomplished with one eye glued to the Pitot tube.

Soon it was necessary to turn again, and, this second venture being accomplished, the aerodrome lay dead ahead.

"Shut off, and go down."

Only too pleased! Off went the engine—down went the nose. The ground came nearer—the machine began to feel strangely light on the controls—my tail wobbled in an eerie fashion.

Mother Earth drew yet closer and closer. Pilot "flattened out" and awaited events or the ambulance.

There was a violent bump as the *tail* met the ground.

Up shot the nose, and, remembering advice so rigidly impressed upon me, open went the throttle.

Suddenly the machine was firm. "Actually on the ground!" The engine was cut off with a sigh of relief. The Flight-Commander rushing up bade me ascend once more.

"No, thank you," was the polite but firm reply.

Subsequent solos followed in rapid succession, the very next one resulting in a forced landing in a field owing to a big end breaking while only 500 feet up. It was lucky the field was there.

Now I have left the scene of my first frenzied flops, and am at present doing dual once again on a tractor machine which really *is* an aeroplane.

Another solo booms threateningly ahead, after which, if I am spared, there may be more to tell.

OBSERVERS ON THE WESTERN FRONT.

R.A.F. kite balloons are the eyes of our guns in France. The observers are highly trained men, and when their balloons are shelled or attacked by enemy aircraft they are forced to make rapid descents by the aid of parachutes.

OVERSEAS SECTION.

A Commentary based upon Practical Experience and a Study of Overseas Opinions.

Overseas Trade after the War.

FOR many years we have persistently urged upon British manufacturers the importance of the Overseas markets and the necessity for improved methods on their part, if these markets are to be retained and developed by British manufacturers—as indeed they must be, in the national interests—after the war. With one or two notable exceptions, British motor cycle manufacturers before the war either failed to realise the importance of these markets, or were content to limit their outlook—and consequently their output—to the demands of the home trade, a short-sighted policy by no means confined to manufacturers in the motor cycle industry.

It is, however, sometimes true that "out of evil cometh good," and there is no doubt that out of this terrible war much good has come for British manufacturers, in that, among other things, they have realised as never before the possibilities and the economy of what is known as "quantity" production, one effect of which has been to revolutionise the methods of pre-war works and factories. The war-time necessity of "quantity" production will prove to be a peace-time necessity also, if British manufacturers are to hold their own against the competition of other nations. "Quantity" production in turn will require that the entire British Empire shall be regarded as the "home market" of the British manufacturer, and this is an entirely feasible and practicable conception of Overseas trade.

Direct Representation of British Firms.

So it comes about that the possibilities of Overseas markets are now being most carefully considered, and plans for their future development are beginning to take shape. One such plan is designed to provide adequate and direct representation of British firms in the most important trading centres Overseas by the establishing of central headquarters, or depots, directly controlled by the home manufacturers, emanating from which headquarters will be up-to-date sales organisations, each covering the whole Dominion or State in which it is operating. Of course, such direct representation may be established by an individual firm, if it be financially strong enough to bear the expense, and this expense be warranted by the volume of business obtainable for its own particular products, but we may assume that it would be impossible for a comparatively small firm to contemplate such a step on its own account, however progressive it might be; hence the suggested development of co-operative representation, which briefly means that a number of non-competitive firms jointly provide the necessary capital and establish such central depots and territorial organisations as those to which we refer. One organisation with this object in view is about to be formed by a group of manufacturers in the motor cycle, tyre, and accessory industries, and it is suggested that operations shall commence in Canada. This, however, we hope will be merely the first step towards similar operations in every other part of the Empire.

IN EGYPT. A D.R. on the road near the Pyramids. Note the width of the bridge, and the fact that the tram rails do not encroach on that part of the road used by other traffic.

Overseas Section.—

Controlling Selling Prices.

THE proposal indicates that the manufacturers concerned realise that the problems of selling and distribution are as vital to the industry as are those of actual manufacture. We cannot emphasise too strongly that upon their successful solution depends the growth of what we are accustomed to call the "movement" in the outlying parts of our Empire overseas. Buyers *must* be able to purchase machines and accessories at prices which are on a level with prices at home, after making proper, but not extravagant, allowance for freight, insurance, packing, and such like necessary charges. The manufacturer *must* control selling prices everywhere and eliminate the series of unnecessary intermediate profits, which, too often, were, and even now are, imposed upon the unfortunate user. Spare parts must be as readily obtainable upon the same reasonable terms.

The Overseas buyer will certainly get his needs supplied on reasonable terms from one source or another after the war. Increased international competition will at all events ensure that condition of things being brought about. The vital question is, will these needs be supplied by British manufacturers or their competitors? We earnestly hope the former, and the development above referred to encourages that hope. But it is a matter which must be taken up seriously by all the manufacturers in the industry. There must be a wider conception of British industry as something of importance, not only to the individuals concerned therein, but as an essential to the growth and development of the Empire as a whole.

We are at last beginning to realise that the well-being of the Empire depends upon the proper recognition and development of its industries, and the individual manufacturer has to recognise that truth and shape his course accordingly.

A Selection of Letters from Readers scattered all over the World.

No English Machines in Ontario.

According to MR. H. HAMILTON, the position of English machines in Ontario is even worse than in Toronto:

"I have lived in Canada for the past five years, and in this city of 27,000 inhabitants there is not one English motor cycle. Indians predominate, with American Excelsiors, Harleys, and Hendersons in the order given. Why is this? Because the nearest English depots are in Toronto, and the objections to English machines are as follow: Very heavy duty on the top of high prices as compared with American twins of high h.p., difficulty and cost of obtaining spare parts, not sufficient h.p., 26in. wheels and small tyres, poor springing front and rear, endless wires, and small lines held together by still smaller bolts and nuts. What is good for English road conditions is not suitable for the Colonies as a whole. A T.T. Rudge frame, 8-10 h.p. J.A.P. engine, three-speed gear box and kick-starter, and 28×3in. wheels, with twist grip control, would be fine, but think of the outlay and duty on such a machine. All chain drive; belt drive is *not* appreciated here."

Roads near Johannesburg.

MR. J. R. MOSLEY, Johannesburg, writes: "I am sending a photograph taken on one of our main roads during the wet season. My mount is a three-speed Bradbury, all-chain drive, which I bought about nine months ago. Since then it has done nearly 15,000 miles, over some very rough roads, and I am highly satisfied with it. It is used as a solo mount as well as a sidecar outfit, and runs quite well as either. I have improved it a great deal by fitting a Binks carburetter."

A Bradbury outfit on a main "road" in the Johannesburg district.

Cars and Cycles in Canada.

A Toronto correspondent, MR. WM. GREENWOOD, writes us on the subject of motor cycle prospects in Canada:

"Knowing that you are interested in trade Overseas, I enclose three cuttings from the Toronto *Telegram* of April 10th, which show the number of automobiles on sale in comparison to motor cycles, and also the low prices at which the automobiles are selling. Can you wonder at the people going in for automobiles in Canada, where we have every facility for storage at home, the advantage in going out when the weather is bad, and in the case of married people with children? The number of Ford cars speaks volumes, and the prices, with the ease of getting new parts! These advantages are all taken note of when the purchaser means business. Some time ago one of your correspondents stated that there were thousands of American motor cycles running round in Toronto. The latest report from the Ontario Government is to the end of March, 1918. Automobile licences, 48,500; motor cycles, 2,000; this gives one automobile to sixty, and one motor cycle to 1,500 inhabitants. It is very important that people writing you should be careful to state facts, as no doubt the English manufactrers are many times influenced by the reports.

"My copy of *The Motor Cycle* did not come to hand for February 14th; maybe the submarine got it. It reminds us that there is a bit of trouble going on somewhere between two or three nations and some unhallowed pirates."

The Question of Wheelbase.

A CANADIAN now serving with the A.S.C., M.T., in England strikes a rather new criticism of the average British machine in the following letter: "As a constant reader of your valuable paper, and a keen Canadian motor cyclist, I venture to express my opinion regarding the ideal Overseas motor cycle.

"As the result of about ten years' experience with both British and American machines, I greatly prefer the former, on account of the better material and workmanship put into it, but, notwithstanding that fact, my after-the-war machine will be an American unless some enterprising British manufacturer turns out a machine which is really suitable for work on Canadian roads.

"One of the chief drawbacks to the British motor cycle for use in the Colonies is its entire lack of comfort, and this, in my opinion, is largely due to too short a wheelbase. Compare the wheelbase of any English machine with that of an American of equal power, and the difference is certainly very noticeable.

"If British motor cycles only had a few American features incorporated within them, such as twist of the wrist controls, 28in. wheels, longer wheelbase, mechanically operated oil pumps, etc., I am convinced that the Colonial demand for them would be enormous.

"I hope that some British manufacturer will endeavour to give us what we want. I am sure he will reap full benefit as a result of his enterprise."

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address

STEEL ROADS.

Sir,—Concerning the proposition put forward by L. W. E. Hartley in your issue of May 16th, *re* sheet steel roads, surely he must realise that in wet weather the number of accidents would be extremely great, owing to the ice-like condition which the surface would assume.

Also, in the heat of midsummer, would not the heat which would radiate from the steel prove very detrimental to the tyres, and also to the comfort of the rider?

Mossley. AYJAYESS.

HEAVY WORK FOR A TWO-STROKE.

Sir,—I see in your issue of May 16th that one of your readers is requiring experiences of a $2\frac{1}{4}$ h.p. two-stroke fitted with a light sidecar. As I have had one fitted to my $2\frac{1}{4}$ h.p. James for the last year, perhaps my experiences may be of some use. Although, of course, fitting a sidecar to any $2\frac{1}{4}$ h.p. comes under the heading "Cruelty to Animals," I must say that my little "'bus" has stood up to the work marvellously. Last summer I made many long runs into the country with a 10 stone passenger, and never once did I have any trouble. I used to average about 90 m.p.g., but speed (if it may be termed such) worked out at about 15 m.p.h. on a sixty-mile trip! How I long for a run on a good old "four."

I can now, of course, only use my bicycle for going backwards and forwards to my work, but still retain the sidecar in order to make the bicycle safer when riding over tramlines in wet weather. T.R.L.

THE POINT OF MAXIMUM EFFECTIVE PRESSURE.

Sir,—As an elementary problem in statics it is clear that, given a *fixed* force above a piston, the position where it exercises its maximum rotary effect on the flywheel is when the connecting rod is at right angles to the crank. For convenience we will call this the right-angle position. Now we know that in an internal combustion engine the explosive force takes a measurable interval of time before reaching its full value. It rises to a maximum, and rapidly falls as the piston descends on the power stroke. It is also clear that a force above a piston can exert no rotary force at the instant when the piston is on the dead centre; and, further, that the position gradually becomes more favourable as the right-angle position is approached. The force may diminish immediately after the dead centre has been passed, but the crank position gradually becomes more favourable. The result of these two opposing factors must be that a point is reached where the maximum *effective* pressure is produced. Where is this point? It appears to me to be not at the dead centre, but at some point between the dead centre and the right-angle position. Will some of your scientific readers kindly give their opinion? H. S. LEFTWICH, Despatch Rider, R.E.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—May we ask the favour of a few lines to reply to "A Few M.T. Fitters, R.A.F.," in your issue of May 2nd? We non-technical privates wish emphatically to contradict their statement *re* motor cyclists *not* doing their own repairs to motor cycles. Evidently they know not what they are talking about or they have never been on active service, as every repair and adjustment that can possibly be done to a motor cycle we *have* to do ourselves. We will give two recent instances, namely, stripping a machine and fitting a new frame, also the *non-technical* job of removing an engine and fitting a new crank case and bushes. These are examples of the jobs we are doing continually, and the only time a machine leaves our hands is when a serious smash renders its complete overhaul by a depôt necessary. We can also say that this is the case of practically every unit on active service. FOUR NON-TECHNICAL PRIVATES, R.A.F.

Sir,—The letter by "A Few M.T. Fitters" is an astounding misstatement. D.R.'s do all their repairs, and are responsible for keeping their machines in serviceable condition. Only in the event of a complete smash up are the machines returned to the repair shops. As a D.R. with over three years' varied experience with the R.F.C. in England and France, I can vouch for this. The idea of an M.T. fitter being required to do "adjustments" and repairs of any description to motor cycles is ludicrous to a D.R. with any experience of service Overseas.

A BROOKLANDS RIDER AND 1st/A.M. D.R.

GUDGEON PIN FIXINGS.

Sir,—In *The Motor Cycle* of May 2nd I notice a paragraph on "Gudgeon Pin Fixings," by "Ixion." My father holds a patent for a fixing. This particular fixing is as follows: The gudgeon pin is taper (standard, more or less), and is about $\frac{1}{8}$in. short each side of piston. Level with end of pin is turned in piston a groove about $\frac{1}{16}$in. wide and about $\frac{3}{32}$in. deep. This groove is at either end if maker thinks fit. *Conical washers* of thin copper are made. The diameter of these washers is the same as that of the pin. These are inserted in gudgeon pin hole and flattened by hitting with a punch or pressed flat. When flat, these washers are expanded into the groove, thereby making a firm fixing. The washers are easily removed by inserting something sharp and prising them out. I would not trouble you with this, only "Ixion" says he has not heard of a better one than he mentions, and, in my opinion, this one is better.

B.E.F. C. H. DICKINSON, Artificer.

Sir,—"Chinook" says, in *The Motor Cycle* of May 16th, that the piston ring method of fixing the gudgeon pin is the best. With this I agree, having been a rider of all makes of motor cycles for the last fifteen years. I have a Rex 1915 8 h.p. twin with the gudgeon pin fixed by a spring ring; and, in my opinion, this method cannot be beaten for safety and accessibility. The Rex Co. have a good many smart ideas in their products, *e.g.*, in the latest 1914 and 1915 models a trough of oil, into which the pistons dip each time, the trough being fed directly by the drip feed. The model (1915) that I have now is their fixed-engine racer, fitted with a B. and B. pilot jet carburetter, geared $3\frac{1}{2}$ to 1. It will tick along in the thickest traffic like a Douglas. I have in the smallest jet that Messrs. Brown and Barlow make for their lightweight, so the petrol consumption would not disgrace a $2\frac{1}{2}$ h.p.; also the oil consumption is very low, as the engine keeps so cool on such a small jet. What the petrol consumption is I will not say, as there are so many unbelievers, but I will say that I have a two-stroke that uses twice as much per 100 miles. My machine has enclosed valves, very silent timing gears, and a quiet exhaust. Even with this small jet the speed is fast enough on war-time roads, and it will climb Sunrising with ease.

G. HARRIS.

MOTOR CYCLES AND THE LUXURY TAX.

Sir,—The following resolution of the Management Committee of the Auto-Cycle Union has been forwarded to the Secretary, House of Commons Committee on the Luxury Tax:

"That, as in normal times a large proportion of privately owned motor cycles are used for professional or business purposes, and as in the present conditions any such motor vehicles can be used only in connection with work of national importance, the Auto-Cycle Union is of opinion that motor cycles cannot in any sense be regarded as luxuries.

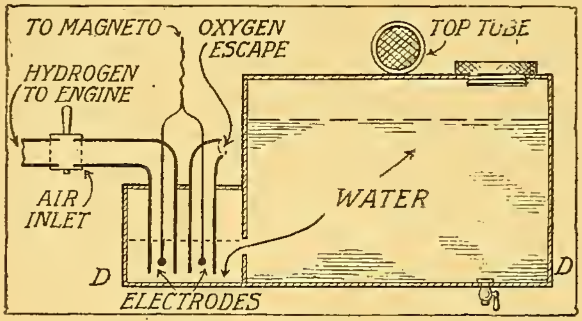
"Furthermore, they would point out that such vehicles are already subject to an annual tax, and that the tax on the petrol consumed by them has been increased since the war. Their manufacture and sale to the public are governed by various regulations made under the Defence of the Realm Act, and any further legislation tending to hamper the production, sale, or use of motor cycles would necessarily be contrary to the national interests."

T. W. LOUGHBOROUGH, G.O.S., Secretary.

HYDROGEN FROM WATER.

Sir,—I note that one of your readers is interested in the use of hydrogen on motor cycles.

For the last three months I have been using water as a fuel on my 211 c.c. Radco with partial success, though it is true I have to start up on petrol.



A method of extracting hydrogen from water.

The current for the decomposition of the water is derived from the earth terminal of the magneto (about 6 volts), but I find there is considerable misfiring at over 15 m.p.h., due, I suppose, to an insufficiency of hydrogen. PILOT.
R.A.F.

CARBURETTER FLOODING.

Sir,—I was returning home the other night after taking a fair singer to her house, where "train and tram were not convenient." It was a perfect spring night. The atmosphere was charged with ozone and flies; my lungs were full of the former and my eyes of the latter, not to mention three of the pests swallowed and one sticking half-way down. My mind still thrilled with the vision of the beauty who, attired in a dream of a cream coat and hat relieved all over by flies, had so recently occupied the sidecar.

I had still six miles to go. It was ten minutes off lighting-up time. My lamps were innocent of carbide. All shops were closed. My carbide tin—yes, with a charge still left—was reposing peacefully beside my goggles in the motor house at home.

Suddenly the dear 'bus—recently new, which had shown my lady on the outward journey how a modern motor cycle should really run—began sputtering, and finally pulled up.

I looked down, and, horrors! petrol was flowing from the new top-feed carburetter, and behaving as though the machine to which it was attached was a suburban watering-cart. With the one eye, with which I could just blink at the time, I peered through the glass disc of the filler cap—of course, after switching off the tap—and, oh! happiness restored. I could have kissed my best love for telling me, if it were not that her tank was covered with the dead and dying—sweet little flies and big fat flies, which had just settled a moment to rest, but, smelling the war spirit underneath, had died in their tracks.

My mind reverted to the nursery story of the horse that pulled up on the edge of the precipice on the dark and foggy night and saved its rider's life. My own charger had acted (or declined to act) in time. Scarcely a cupful had been wasted. A fortnight's allowance was saved.

Everything about the carburetter seemed snug and tight. I decided to push on and dispense with the services of the float chamber, by just turning on a supply as required. After a mile like this I left on the tap and peered through the gloom in the region of the jet. It did not seem to flood. I held my hand under—of course, burning my thumb in the process—but, no, the fly somehow must have extricated itself from the needle valve and found its way into the combustion chamber, where it intended to nest and amuse its young with the electric lights on the plug, but found instead its "future state."

I arrived home fifteen minutes after lighting up time. The police were in the pubs. What a mercy policemen drink!

At last encased in an easy chair and slippers, the first thing that met my eye in an old copy of *The Motor Cycle*—to be precise, page 270, of September 20th, 1917—was a paragraph on "Fits of Flooding," by "Ixion," who declared he had "yet to meet a case of vibration flooding with a top-feed vaporiser." How now, Sir "Ixion"?

Audley. FLYPAPER.

ANOTHER USE FOR SCIENTIFIC WELDING.

Sir,—Quite the most striking feature of the first shipping returns published since Lord Pirrie assumed office was the relatively high proportion of ships that within the specified period had been repaired and returned for use in the nation's interest. But, excellent as the results were, we have reason to believe that a much greater volume of tonnage may speedily be restored by scientific welding, if only the authorities will take full advantage of the business organisations already existing to execute work of this description. In proof of this, we need do no more than point to the feat of the American engineers, who, largely by the aid of welding processes, brought back into commission, in a short period, seventy German ships, with a total of over half a million tonnage, which enemy crews had deliberately damaged. A sufficiency of seaworthy ships may well become the vital factor in the war. For Britain, ships, so to speak, constitute the very life blood, whilst the Allied cause in general will in future largely depend upon the ability to transport and feed the millions of American soldiers who are to be shipped to France and Flanders.

BARIMAR, LTD.,
C. W. Brett, Managing Director and General Manager.

PETROL AND OIL CONSUMPTION.

Sir,—Some months back I read a letter, signed "Snostone," regarding oil and petrol consumption.

Like the writer, I am using a motor cycle every day except Sundays, even when 8in. of snow falls in a day. I have at present two machines, but run a 1916 3½ h.p. Sunbeam with three-speed gear, Sunbeam leg shields, and always carry full kit with me, so that my load appears to exceed that of your correspondent "Snostone."

My own weight is just about 11 stones, and I average 120 m.p.g. solo with war petrol, and 4,000 m.p.g. Vacuum B oil. Perhaps I should state that I commenced motor cycling fourteen years ago, and have owned six machines, as well as riding occasionally on other machines, and during the whole time I have done all my own repairs and am always experimenting. It is to be hoped, therefore, that I have passed the "novice" stage.

With a heavy coachbuilt Millford sidecar I can run 90 m.p.g. on average roads. Apart from the carburetter—a three-jet Binks—and a hot air device of my own, the machine is "standard," and as it is intended in peace times for use chiefly with the sidecar, the gear is low—5¼ to 1. Perhaps that is why I have never attained 75 m.p.h., as claimed by another Sunbeamist!

In conclusion, may I thank you for the excellent articles by Mr. Moore and other writers, which are especially interesting to anyone with chemical and engineering knowledge.

May I also say, as a past owner of a German motor cycle and several Hun magnetos, that my present English make gives the easiest starting and hottest spark of the lot. The magneto has never been touched for 3,700 miles, and for all reasons I shall leave Mr. Ives and his followers to their own fate. They strike me as very similar to the people who imagine that only a foreigner with long hair can play the piano. H. WALKER.

PREPARATION OF POST-WAR MODELS.

Sir,—The Ministry of Reconstruction has under consideration the possibility of granting assistance to manufacturers in the motor and allied industries in the matter of the construction of experimental post-war models of their products.

I should therefore be glad if you would give publicity to this invitation to all such manufacturers to forward to the Secretary of the Motor Industry Branch Committee of the Engineering Trades (New Industries) Committee, 39, St. James's Street, S.W.1, a statement of their requirements in this connection. This statement should represent the most moderate demands possible. It should include estimates of the bulk weight of the different materials required, and should also cover patterns, tools, and other requirements in connection with the manufacture or testing of experimental models. It should also state requirements in respect of labour needed for the production of such experimental models with a view to possible arrangements to permit employment of labour in this way.

Manufacturers are reminded that if it proves possible to complete arrangements in their interests, it remains certain that the facilities which it will be possible to grant will be very limited, and that demands should be framed accordingly.

All statements of requirements must reach the offices of the Branch Committee not later than June 10th.

H. C. B. UNDERDOWN,
Chairman of Motor Industry Branch Committee.

CARBURETTER ADJUSTMENT.

Sir,—I thank you for your kind publication of my little "grouse" at the Binks carburetter's peculiarities. I desire specially to thank the reverend and other gentlemen who have taken the trouble to state their experiences.

I do not claim any special privileges in relation to your already congested space, therefore I will merely state that my conclusions, after carefully studying the pleasures and troubles of your correspondents, are that there is strong suspicion of a weak point in the Binks in the neighbourhood of the main jet, and that it is quite possible that the suction, when the throttle is fully open, might be improved from within, and so prevent that feeling one experiences when opening on to the main after running enjoyably on the second. The feel would best be described by the suspicion that some outside agency had just there and then lifted the top off your engine. The majority, apparently, get along best on a large main such as 9 or 10, but I, singularly enough, never had any decent results from other than a small main jet, such as a 5, and am not desirous, at the present price of petrol, of using 9 or 10 if avoidable.

These little exchanges of views, however, do not do any harm, rather act as an incentive to perseverance, and I certainly shall endeavour to take it out of the Binks when the air has become clearer. H. A. GONNELL.

FRENCH ROADS.

Sir,—As a D.R. who has had two years' experience on divisional and brigade work out here, I venture to offer a few criticisms to the remarks of your correspondent "Tampion."

He expresses surprise that French *pavé* roads are generally disparaged, but really his praise of these roads is a far greater source of astonishment to us D.R.'s than the fact that most writers agree in their condemnation of them. It would be interesting to know how many speed bursts your correspondent has indulged in on these wear-resisting highways, and an exhibition of his powers in cornering at speed in wet weather when the *pavé* is greasy would no doubt be instructive.

Is your correspondent aware that on the majority of *pavé* roads out here it is well-nigh impossible to use top gear on a W.D. Triumph if the road is at all badly worn, and in a greasy condition? I have certainly never encountered a road surface in England so calculated to test one's capabilities for sticking on as a *pavé* road under bad weather conditions, and I feel sure that if our own road authorities started to lay down *pavé* roads, as your correspondent suggests, he would have a difficult task in finding anyone to share his gratification.

I should be interested to know on what part of the Front "Tampion" has seen shell holes filled in with sand bags covered with gravel, as I have at one time and another been on most parts of the British Front, and have yet to come across this extraordinary phenomenon. I quite agree with your correspondent that the roads in the shell zone are bad, but I cannot say that, in my experience, they cause my back tyre to burst "with alarming regularity."

His remarks about Triumph forks make one doubt whether his experience of motor cycling is as extensive as he would have us believe, for while having nothing but praise for the all-round efficiency of this machine, I think you will find that the fork is notoriously one of its least satisfactory features. The spring is continually breaking, and the front wheel bounces about on the road, and makes one wonder whether the fork was designed in collaboration with the leading tyre manufacturers. DON. R.

B.E.F.

LONG V. MEDIUM STROKE ENGINES.

Sir,—Allow me to say a few words in favour of the long-stroke engine. Two important points seem to have been left out of the article by "Mohandis," namely: (1.) That the ratio $\frac{\text{compression space area}}{\text{compression space volume}}$ is smaller in the long-stroke than in the short-stroke. This, of course, assuming that the compression ratio is the same. Hence the heat lost when ignition takes place is less in the long-stroke than in the short. (2.) Having found that the *total* cooling surface in the line of motion is 11% greater in the long-stroke than in the short-stroke, the obvious conclusion would be that the maximum temperature reached during compression is lower for the long-stroke. And since it is the temperature at end of compression that limits compression, we may use a higher compression ratio in the case of a long-stroke, which results in a gain of thermal efficiency. B. BRESLAU.

SPRINGING THE SIDECAR WHEEL.

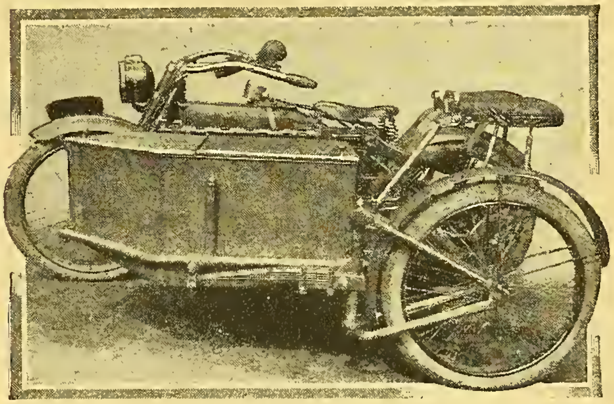
Sir,—Enclosed I have the pleasure in sending you a photograph of my design of a sprung sidecar wheel.

The design as shown combines a castor wheel with a cantilever spring and a locking arrangement. The castor wheel can be secured so that the wheel only can be moved in a vertical direction. The locking arrangement is placed on the back stays of the sidecar wheel and the sidecar frame, and is made strong enough to withstand all side stresses in taking corners, etc., but it in no way hinders the wheel in its vertical motion. The arrangement, therefore, can also be used without the castor wheel, and thereby the manufacturing price can be lowered; but, in many respects, the castor wheel has advantages, so I personally prefer the combination and the simple locking arrangement for setting the castor wheel out of action where the conditions are such that this is preferable.

The motor carriage shown is used by one of our Volunteer Corps, and carries two men on the motor cycle and one in the sidecar, and, further, there are mounted two or three automatic rifles on the sidecar and ammunition in the steel cases.

The weight distribution on this sidecar is much better than on the ordinary pattern, and therefore I think that this spring improvement would be of great value in connection with the machine gun or the ambulance sidecar.

Denmark. HERSLEB CHRISTIANSEN.



A sprung wheel machine gun sidecar fitted with a castor wheel that can be locked or released whilst in motion.

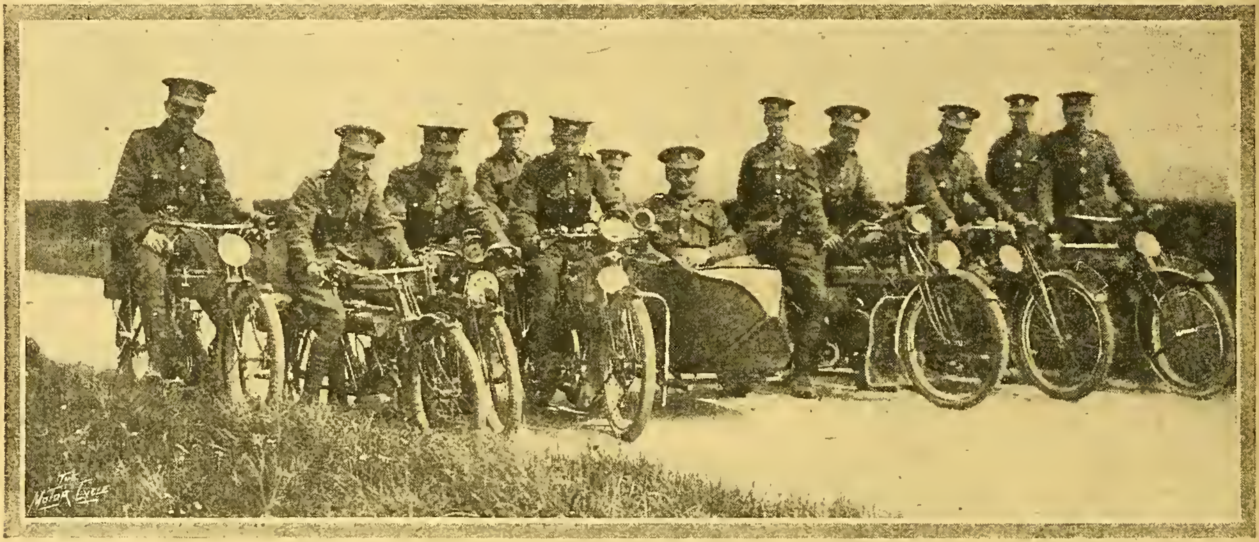
Test Run of the East Yorkshire M.V. Corps.

On Whit-Monday, the East Yorkshire Volunteer Corps, now one of the strongest motor volunteer corps in the country, held a test run. This corps has a membership of some three hundred and forty-seven officers and men, and includes motor cycle, light car, and car sections, heavy vehicles, and a strong detachment of ambulances and drivers.

Major A. J. Atkinson, who is in command of the corps, and to whom most of its popularity and success are due, was at the head of Monday's test run, being preceded by two motor cyclists; ten other motor cyclists took part in the run, whilst sixteen cars formed part of the procession. The run was from Hull, through Collingham, Beverley, Driffield, to Bridlington, where a stop of two hours was made before the return.

Lunch, which was carried by the men, was taken at the roadside, whilst the object of the test was the important one of ascertaining the exact distance to be kept by military cars from each other on a mobilisation, and the practice of the various signals used in the Army for motor vehicles on the move.

The test was an entire success, and much useful information was obtained, whilst a pleasant day was spent at the expense of a small quantity of the members' petrol, as it could not be provided by the authorities.



A section of the East Yorkshire Motor Volunteer Corps starting for their test run.

A Sketchy Reminiscence.

There are occasions when across the human brain flashes a series of pictures, or, to modernise, a "cinema film" of past incidents, generally without connection with or bearing upon the occupation of the moment.

There are periods of monotony for the man on active service when these mind pictures come dancing into one's head, and a few minutes pass in that state of absentmindedness quaintly termed a "brown study." By a seeming spirit of contrariness, a D.R.'s period of inactivity outside some headquarters' office, in a shell-battered cottage, with a squelch of Flanders mud around, and a cold, soaking drizzle falling, may be alleviated by some glimpse of a past summer such as the following:

A misty morning, seven o'clock, Lynmouth—that glory of woods and streams, of brown moorland water surging among boulders, under a roof of green foliage pierced by streaming shafts of sunlight.

To many a trials rider all these may have meant nothing more than a nightmare of hills and hairpin corners, with abominable surface of red mud and stones. On the morning of which I think, the moisture-laden atmosphere, which heralds a hot day, was hardly sufficient to lay the dust. By the time the tank had been filled, a few necessary adjustments made, and the hotel bill settled, the sun was making grand play upon the towering piles of woods above the Lyn. An easy climb out of the village over the new-cut road soon opened up before me the open air and rolling country of Exmoor. The road wound around heather-clad downs, still an indistinct blur of purple in the morning air. No hurry; this is no time for 30 m.p.h., but the slower the better. Disturbance of this peaceful domain by raucous exhausts seems almost a sacrilege. A quiet progress has another advantage: aided by a light breeze in my face, a turn of the road round a small bluff brings me unexpectedly upon a stag and two hinds. Magnificent creatures; the stag carrying a fine pair of antlers of many tines. I have a memory of rich red-brown coats and the curious curling up of the lips as they feed; then a startled stare, a toss of the splendid heads.

A peremptory order brings me back to earth in the squelching misery of winter in Flanders, and the vision is gone. But what a treasure house is memory!—F.S.

QUESTIONS & REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Book on Magnetos.

Can you inform me if there is any book that deals with magnetos more fully than your "Motor Cycles and How to Manage Them"? This is very good, but it does not go deeply enough into the theory of the subject. I also require one that explains car magnetos. —H.B.

We recommend you to obtain a copy of "Electricity and the Motor Car," which deals with all types of magneto. This handbook is obtainable from *The Motor Cycle* offices, 20, Tudor Street, London, E.C.4, price 2s. 10d. by post.

Difficult Starting and Blowing Back.

I have recently had a magneto fitted to my twin Sarolea engine, and I am having much trouble in starting. (1.) When the engine is cold it will start up the first pull over, after I have primed it, but when I stop it I cannot start it again until it has stood for a few hours. I have primed the engine when warm, but to no purpose. There is always a good spark with old and new plugs, and there is also good compression. The magneto is a very small one, but nearly new, only it has been standing for some time. Do you think that it wants remagnetising? (2.) Can you tell me the reason for petrol blowing out of the air inlet of the carburetter when the engine is running? The carburetter is a B.B., with a needle running from the throttle to the jet. Do you think this is suitable for a twin, as the engine runs very unevenly? I use No. 3 petrol.—S.A.E.G.

(1.) The trouble is certainly rather a mysterious one. It might possibly be cured by using a slightly wider spark gap. The exact cause is not apparent, but it might be due to condensation across the plug points, or oil on the plug points. We do not think the magneto is likely to be at fault in your case, otherwise it would not start the engine in the first instance. (2.) The carburetter, if properly tuned, should be quite suitable. If petrol blows back through the inlet pipe all the time the engine is running, it is probably because you have too weak an inlet valve spring. If the blow back only occurs when the engine is stopped after running a few seconds, and petrol drips out of the inlet pipe, it is due to condensation of petrol on the walls of pipe and carburetter. Try taking the air in warm by connecting the air inlet to a muff surrounding the exhaust pipe.

Balancing a Two-stroke Engine.

I am riding a Paragon two-stroke, which runs well up to about 15 m.p.h.; if I exceed that speed, it seems as though everything inside was loose. The bearings are new and a good fit, both ends of connecting rod tight, and no side play. Do you think it can be the balance, and how can I find out? Will you please let me know the way to find the correct balance?—A.E.S.

How to balance an engine is fully set forth in our handbook "Motor Cycles and How to Manage Them." The chapter on the subject is a long one, so that you will understand that it is impossible on this page to give all particulars as to how to balance an engine. Briefly, the mechanical balance is arrived at by adding the weight of the rotating and half the weight of the reciprocating parts to the flywheel at a point opposite the crank pin. What you complain of is probably due to a loose-fitting piston; that it is due to bad balance is rather improbable. Another cause may be that the engine is particularly dirty. This will cause pre-ignition, and you may mistake the "pinking" noise of the pre-ignition for a rattle of the bearings.

The Correct Size Jet.

Having recently bought a second-hand Bradbury, I should like your advice. I think I am wrong in the timing of the magneto, so if you will help me I shall be very much obliged. (1.) Is there a standard size of jet for this machine? The carburetter is a B. and B. with a jet marked 34. (2.) Will you kindly give me the timing for the magneto? (3.) In putting the engine together I find there is a crack in the exhaust valve seating, extending down the cylinder and 1¼in. into the exhaust chamber. Is it possible to have this repaired by welding?—R.H.

(1.) We should say that a 33 or 34 jet would be correct. (2.) The magneto timing should be as follows: Place the piston exactly on top dead centre of compression and firing strokes and connect up the magneto with the points just about to break and the ignition two-thirds retarded. (3.) We should say that the crack could be welded satisfactorily by the oxy-acetylene process, but it depends on where it is. You had better submit your cylinder to one of the well-known welding firms, and ask them if they can guarantee to make a good job of it.

Motor cyclists of the West Riding Volunteers partaking of an impromptu lunch by the roadside. See page 530.

Flywheel out of Truth.

I have a 1913 Douglas, and, after taking it down to clean it, I took the flywheel off, and on reassembling it I find it is out of line and wobbles, and, no matter what I try, I cannot get it right. The main bearing seems all right, and there is no vertical play. (1.) Will you please tell me the cause and remedy? (2.) Also, what pistons will fit a 1910 Douglas?—C.S.

(1.) It is possible that you have not got the flywheel properly on the key, as if it were running truly before you took it off it should go back in truth. The only fault of which we can think is that you have not replaced it correctly and it is riding on the key. Better remove it and have it tested in a lathe by fixing it on a true mandrel and running it between centres. (2.) The only pistons which will fit a 1910 Douglas are Douglas pistons of the 1910, 1911, and 1912 models.

Composition of Dry Batteries.

Can you please inform me how to refill a dry battery? If so, I shall be greatly obliged.—G.W.

The interior of a dry battery usually comprises a zinc outer casing (to which is connected one of the terminals) and a central carbon rod or plate (to which is attached the other terminal). Around the carbon rod or plate is packed a mixture of crushed carbon and manganese, and round this is packed some absorbent material, which varies according to the make of the cell. Some use spun glass, others sawdust, etc. Without knowing the make of your cell, it is impossible for us to tell you how to refill it. We may say that it hardly pays to refill old dry batteries, as new ones can usually be bought for less than the cost of the materials. In many instances it is possible to get a little more current from an exhausted dry battery by immersing it in a strong solution of sal-ammoniac in water. Drill a number of small holes in the base of the battery, and immerse it in the solution for several hours.

Change Speed Gear Conversions.

I have purchased a second-hand 3½ h.p. clutch model single-geared Triumph of about the year 1912. I have attached a sidecar (light), and would like to be able to negotiate hills a little better with a passenger. Can you please inform me whether a three-speed hub wheel of later date would fit the rear forks if I could manage to buy one? Also do you know of any two-speed gear which I could attach? If not, which would be the most suitable means of attaining my object?—NOVICE.

We should not recommend you to buy a three-speed hub wheel for sidecar work. It would be rather difficult to fit, and might not give you satisfaction when you have fitted it. You might obtain, by advertising in *The Motor Cycle*, an N.S.U. engine-shaft two-speed gear, which could be fitted quite easily. Alternatively, a Philipson pulley would be of considerable assistance on hills of moderate gradient, this being a pulley to provide automatic changes in gear ratio.

Paraffin Vaporisers.

Can you tell me if the Silver or Morgan vaporiser would vaporise paraffin effectively on a Morgan Runabout? I shall also be much obliged if you would give the addresses of the makers of both.—R.B.

We have had no practical road experience with either vaporiser, but we understand that both are quite satisfactory. The makers' addresses are: the Morgan vaporiser—Mr. Morgan, 74, East Hill, Wandsworth, London, S.W.; and the Silver vaporiser—Mr. T. Silver, Quadrant Co., Lawley Street, Birmingham.

Timing of Small Engine.

I have a J.E.S. auxiliary set, which I am anxious to keep till after the war. I want a new cam wheel, but cannot obtain one. I got one made at a local garage, and a gap of $\frac{1}{8}$in. has been left between tappet and valve. Is this correct? The timing also does not seem correct; the exhaust valve closes before it reaches the top dead centre of exhaust and inlet strokes. How can I alter this?—G.N.R.

The gap between tappet and valve is far too great; it should not exceed the thickness of a thin visiting card, slightly less than $\frac{1}{64}$in. If you set the timing wheels for exhaust valve to be down on its seat when the piston is on dead centre of exhaust and inlet strokes, the new cam should make the valve *commence* to open, not *be* open, when the piston is within $\frac{5}{16}$in. from the end of firing stroke.

To Every Reader of "The Motor Cycle."

IN view of the serious shortage of paper it is desirable that readers of "The Motor Cycle" should place *definite orders* with their newsagents for copies to be reserved or delivered weekly. ¶ The custom of chance buying leads to wastage of paper, as copies ordered for casual purchasers may be left unsold, owing to fluctuating demand. ¶ On the other hand, if standing orders are given, newsagents and publishers can regulate the supply so that, *while the requirements of regular readers are satisfied, the risk of wastage is reduced to the minimum.*

If YOU have not already done so, please give a definite order THIS WEEK, and thus assist to economise paper.

Constant Pressure v. Constant Volume Type of Engine.

Have any experiments been made on the following lines? A spray of liquid fuel, such as petrol, will, if injected into a vacuum, instantly vaporise. Further, an engine of the constant pressure type, for automobile work, would be much more economical than the constant volume type. I suggest an air-tight vaporising chamber with automatic jet inlet, and outlet connected to a pump driven by the engine, the pump to draw the vapour from the chamber and to force it into the cylinder at correct time through a needle valve; sparking plug placed close to needle valve; extent of vacuum in vaporising chamber to be adjustable.

(1.) Would the compression of the vapour in the pump condense it, or would the generated heat by quick compression retain it as vapour? (2.) Is not the suction of a constant volume type sufficient to create enough vacuum in the vaporising chamber to vaporise a spray before admixture with air?—H.L.B.

So far as we know, no motor cycle engine has been made on the lines you suggest. While we are of the opinion that the vapour would not be condensed by the pressure of the pump, we think that the suction would be sufficient to vaporise the spray. We regret we cannot give you a more definite opinion on the subject.

Alternative Routes.

I have been granted a small quantity of petrol for my leave, and intend to ride from Marlborough (Wilts) to Chester. Two routes are advised: one *viâ* Swindon, Cheltenham, Tewkesbury, Worcester, Kidderminster, and Wellington; the other *viâ* Newbury, Oxford, Rugby, Wolverhampton, and Newcastle-under-Lyme. Would you be so good as to inform me the better route, in your opinion?—M.A.H.

We advise the route *viâ* Cheltenham, Worcester, and Wellington. The alternative suggested is not only a longer route, but going to Rugby and then to Wolverhampton would be almost equivalent to retracing your steps.

RECOMMENDED ROUTES.

BRAMSHOTT TO ORPINGTON.—W.J.P.

Bramshott, Hindhead, Godalming, Guildford, East Clandon, Great Bookham, Leatherhead, Epsom, Sutton, Croydon, West Wickham, Orpington.

HULL TO BURTON-ON-TRENT.—E.R.T.

Hull, by ferry to New Holland, Brigg, Gravingham, Blyton, Gainsborough, Retford, Worksop, Mansfield, Sutton-in-Ashfield, Alfreton, Derby, Burton-on-Trent.

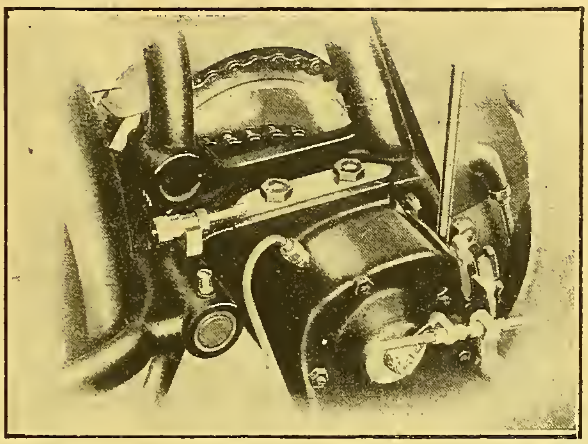
RUGBY TO NEW BRIGHTON.—J.S.

Rugby, High Cross, Atherstone, Weeford, Lichfield, Armitage, Rugeley, Weston, Stone, Pipe Gate, Woore, Nantwich, Tarporley, Chester, Birkenhead, New Brighton.

A Post-War Feature of the

1918 Powerplus Indian Motocycles

We regret that we are not in a position to supply motorcycles at the present time, but we can send 1918 abridged descriptive lists on application. This applies to Great Britain — only. —



The Powerplus Gear Box showing micrometer adjustment. By turning the nut at the left, the box can be moved to get the correct tension on the short chain.

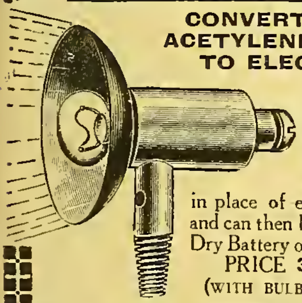
Volex MOTOR CYCLE LIGHTING.

CONVERT YOUR ACETYLENE LAMPS TO ELECTRIC.



This improved type will be appreciated by all users. The adapter screws in place of existing burner, and can then be wired up to a Dry Battery or Accumulator.

PRICE **3**/- EACH
(WITH BULB **1**/- EXTRA).

We also supply above set complete with 4 volt "Volex" Aero Battery, Bulb, and Twin Cord.
18/- per set.

"VOLEX" DRY BATTERY ELECTRIC LIGHTING SET FOR MOTOR CYCLE AND SIDECAR. OR SIDE AND TAIL SET FOR LIGHT CAR.

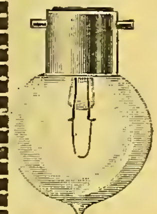
If desired, we can supply Accumulator Sets instead of Dry Batteries at the same price where Accumulator charging is convenient.

This outfit comprises a complete installation for the electric lighting of a motor cycle and sidecar. It includes best quality Motor Cycle Head Lamp with Switch Attachment, as illustrated. Sidecar Lamp with Switch Attachment. Tail Lamp with switch and bracket for attachment to Carrier of Motor Cycle, or to back of Sidecar. One Set of Bulbs and one Spare Set. Set of "Volex" Batteries (this can be carried in bottom of sidecar). Complete wiring and connections. A Handsome Lighting Set, giving splendid results, and designed to ensure extreme ease in fitting.

Price £7 : 5 : 0 Complete as illustrated.

Head or Side Lamp as above, with 4 volt Battery, in Satchel, and Bulb and Cords, **57**/- complete.
Head and Rear Set, as above, with 6 volt Battery, in Satchel, complete, **83**/-.
Torpedo Tail Lighting Set, complete with Lamp, as above illustration, Cord, Bulb, and 4 volt "Volex" Giant Battery, in Satchel, **42**/- each.

IMPORTANT.—ACCUMULATOR LIGHTING SETS CAN ONLY BE SUPPLIED WHEN ORDERS ARE ACCOMPANIED BY PRIORITY CERTIFICATE.



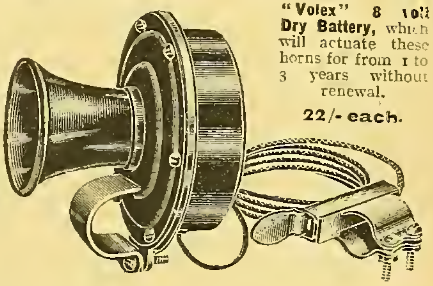
THE "W. & G." Special Metal Filament Bulb

When ordering, state whether for use with Dry Batteries or Accumulators. Miniature screw, 2, 4, and 6 volt, **1**/- each.
Small Bayonet Cap, 2, 4, 6, & 8 volt, **2**/- each

CLAROVOX MOTOR CYCLE HORN.

Powerful Electric Motor Cycle Horn, black enamel finish, with push attachment and connecting wires and bracket complete.

No. N 34/19 £1 : 0 : 0 each.
Limited number only



"Volex" 8 volt Dry Battery, which will actuate these horns for from 1 to 3 years without renewal.
22/- each.

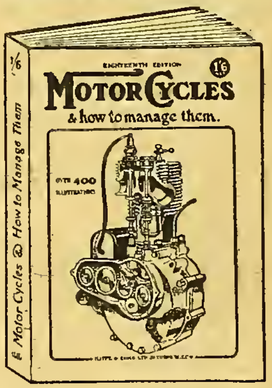
The sale of this book is fast approaching a quarter of a million copies



— which proves its usefulness to motor cyclists.

"Motor Cycles and How to Manage Them" is, in fact, the one book that no motor cyclist should be without.

This edition (the eighteenth) is bigger than ever and better than ever—over 350 pages, with more than 400 illustrations, covering all types of machines and every conceivable aspect of their care and management. Each part of the machine, from engine to speedometer, is fully dealt with. Service riders will find it particularly helpful.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

TRIUMPH, 1914 model, 4h.p., 3 speeds, complete with brand new Montgomery coachbuilt sidecar, and all accessories; £50.—Maudes', 100, Gt. Portland St., London, W.1. [5571

AIR Mechanic must dispose of 1916 countershaft Triumph and best Gloria sidecar, lamps, horn, etc.; this is a splendid outfit, and genuine bargain at £80; seen London.—Box L6,287, c/o *The Motor Cycle.* [5493

TRIUMPH, 1910, 3½h.p., free engine, Philipson pulley, Bowden control, fixed 1917, nice wicker sidecar, with waterproof apron, box fitted on chassis of sidecar (colour to match), with travelling bag inside for spares, etc., special petrol tin, Cowey speedometer, horn, tools, watch, two new Lomax toolbags, A.I. mud and wind screens fitted 1917, two new lamps on cycle (once lit), lamp on sidecar, three new Dunlop covers, heavy on back and sidecar, new belt, all fitted 1917, many spares, including three covers, two Clinchers, one Avon, two new tubes (Dunlops), never been used, new valve, new Lodge plug, belt, belt fasteners, etc., petrol soldering bolt, in splendid condition, been well kept; nothing wanting to make it perfect, magneto rubber covered, mileage 9,891, never used 1912-13, or since April, 1917; no offers; £42.—Neave, 135½, East High St., Forfar. [5466

Zenith.

ZENITH-GRADUA, 1915, 4h.p. twin, T.T.; £36; exchange entertained.—5, Victoria Av., Surbiton. [X4889

ZENITH, Gradua gear, Jones speedometer, and horn; £45; E.P. or exchange.—Service Co., 292, High Holborn, London. [X4733

ZENITH Combination, 8h.p., hood, screen, good condition; bargain, £33/10.—G.H., 168, Green St., Forest Gate, Essex. [X4898

1917 3h.p. Zenith, countershaft model, kick starter, and free engine, complete with all accessories, twin-cyl. J.A.P. engine, very fast, in good sound condition; £57/10; guaranteed.—Wauchope's, 9, Shoe Lane, London. [5594

Miscellaneous.

JAMES, 1915, 2¼h.p., 2-stroke, 2 speeds, excellent condition; £32.—See below.

JAMES, 1916, 2¼h.p., 2-stroke, 2 speeds, lamps, and horn; £36.—See below.

JAMES, 1917, 2¼h.p., 2-stroke, 2 speeds, lamps and horn; £40.—See below.

JAMES 1915 4¼h.p. Combination, 3 speeds, clutch, and kick starter, all-chain drive; £60.—See below.

ROYAL Enfield, 1916, 2¼h.p., 2-stroke, 2 speeds, lamps, and horns; £38.—See below.

ROYAL Enfield Combination, 1916, 6h.p., lamps, horn, and speedometer; £78.—See below.

DOUGLAS, 1910, 2¾h.p., lamps and horn; £15.—See below.

DOUGLAS 1913 2¾h.p., Model V, head light, rear lamp and horn; £28.—See below.

DOUGLAS Combination, 1915, 4h.p. Lucas lamps and horn Stewart speedometer and warning signal; £63.—See below.

WOLF-J.A.P., 1915, 2½h.p., countershaft 2-speed gear; £20.—See below.

ALLON, 1915, 2¾h.p., 2-stroke, excellent condition; £25.—See below

ALLON, 1916, 2¾h.p., 2-stroke, excellent condition; £30.—See below.

ALLON, 1917, 2¾h.p., 2-stroke, 2 speeds; £40.—See below.

CALTHORPE, 1915, 2¼h.p., 2-stroke, 2 speeds, lamps, and horn; £27.—See below.

RUDGE, 1916, 3½h.p., Multi gear and clutch, lamps and horn; £42.—See below.

TRIUMPH, 1910, 3½h.p., T.T. model, speedometer; £20.—See below.

PREMIER, 1913, 3½h.p., countershaft gear and clutch, fitted with coachbuilt sidecar; £38.—See below.

PREMIER, 1913, 3½h.p., and tradesman's side-carrier, 3 speeds, clutch, and starter; £50.—See below.

PRECISION, 1915 4h.p. twin, 2-speed countershaft gear; £35.—See below.

NEW Imperial-Jap, 1915, 2¾h.p., 2-speed model; £27.—See below.

CLYNO Combination, 1914, 6h.p., hood, screen, detachable wheels and spare wheel, complete, lamps, horn, and speedometer; £62.—See below.

A.J.S., 1912, 6h.p., 2-speed countershaft gear, clutch and kick-starter, and Gloria coachbuilt sidecar; £35.—See below.

INDIAN 1914 7h.p. Combination, spring frame, dynamo lighting, electric starter, horn, speedometer, etc.; £60.—See below.

ALL the above motor cycles are ready for immediate delivery, and deferred payments can be arranged for any of them.—Write for further particulars and list B. 22 to the Eastern Garage Co., 418, Romford Rd., Forest Gate, E.7. Telephone No.: East Ham 490 T.A.: Egaraco, London. [5577

WELL and truly made from forged steel, "King Dick" Spanners grip "fair and square." They cannot burr a nut when properly adjusted. Famous for 35 years: guaranteed for ever. Four sizes, 3in. to 9in.

See that your spanner is stamped with the Bulldog mark here shown—the mark of the genuine "King Dick."

Orders dealt with as Government requirements permit.

ABINGDON ECCO, LTD., Tyseley, BIRMINGHAM.

The Development of the Motor Cycle.

IT is interesting to speculate how far the motor cycle will have been improved, say, twelve months after the cessation of hostilities. By that time manufacturers should have supplied some of their post-war models to customers. In this short article we do not intend to prophesy concerning detail improvements, and it suffices only to say that improvements are necessary, and are demanded by the *cognoscenti* of the motor cycle world.

Our contributor, Mr. Francis E. Schofield, in his able article "The Trend towards Mechanical Luxury," was clearly on the right lines when he showed how rapidly the motor car developed in comparison with the motor cycle. The question is one which makes an interesting study. Why, for example, when the motor car was comfortable, silent, and absolutely reliable, had the twin-cylinder motor cycle of that period automatic inlet valves, more often than not a single gear, and a hit-and-miss system of lubrication? The answer may be because the motor cycle was then evolved chiefly by pedal cycle makers, who were not engineers, but people who treated the motor cycle not as a real engineering proposition, but as a bicycle with an engine hung on to it; because motor cyclists, not having had car experience in many cases, did not know enough to demand obvious improvements; because manufacturers, who must have known at the time what was required, wisely, from their point of view, altered their designs as little as possible, for their products, crude as they were, sold as fast as they could be manufactured.

But this war has taught us a great many things. Is it likely that the enthusiastic motor cyclist who was content with a single-geared two-stroke in 1914, but has driven a staff car during the war, will be content when he returns to his beloved two-wheeler to ride a vehicle which makes an unnecessary noise, smears his clothes with oil, and cannot be restarted on a steep hill if brought to a standstill through the exigencies of traffic? We know, of course, that most modern machines are far more highly developed than this particular type, but the type existed, was sold, and, we believe, enjoyed by those who did not know the delights of anything better. No one will pretend that the up-to-date pre-war machine was perfect, good though it undoubtedly was, and we feel sure that, after all the war has taught our cleverest engineers, the post-war machine will be a very different proposition. Clever brains, we know, are busy plotting out new designs, and not a few of the most promising plans have actually first seen the light in depots within sound of the enemy's guns.

Commercial Post-war Aspects.

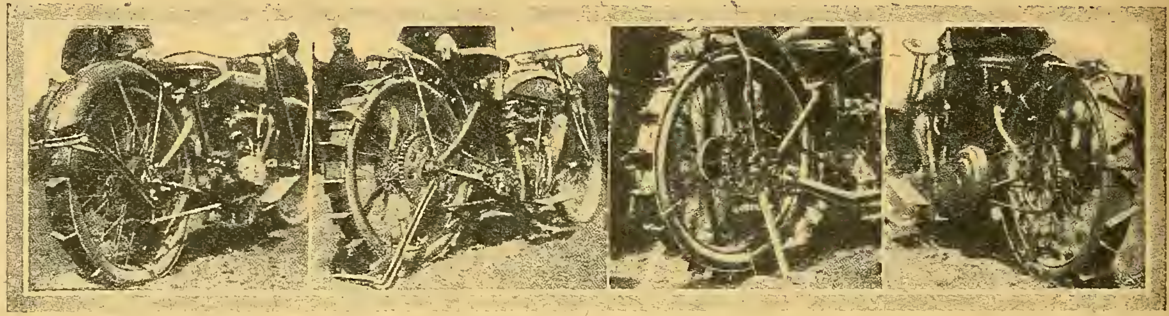
So much depends on our ability to increase our exports after the war to enable us to recover from the ravaging effects of the struggle on which we are now engaged that it is clearly the Government's duty to encourage every industry as much as possible, to foster a limited amount of experimental work, and, at the earliest possible moment, to remove the fuel ban and to enable cheap fuel to be supplied to the public as a detail of its encouragement of our particular industry.

The Ministry of Reconstruction is fully aware of this necessity, and, as we pointed out last week, is intending to help manufacturers in their experimental work. At the present time we hold the lead in the manufacture of motor cycles. No other nation can even approach us in this particular direction; and it is a lead which we must keep. Our machines, therefore, must continue to be the best, and must be sold at a price in the Overseas Dominions which will compare favourably with that at which makes of other nations can be bought in those far away portions of the Empire. Our manufacturers *can* rise to any occasion that may arise, but only with Government assistance. It is up to them to show the Government what they can do, and up to the Government to enable them to do it.

An index to the advertisements in this issue will be found on the page facing the back cover

AN AMERICAN HILL-CLIMB.

A Spectacular Event witnessed by 9,999 People according to the American Report.



Some of the treads which were fixed to the rear wheels of competing machines. The varied designs of these "tractors" show that each rider had his own peculiar idea as to the best means of gripping the surface

A HILL-CLIMB was recently held on Capistrano Hill in California. This is no more than a bald statement of fact, but apparently it is paradoxically untrue because the climb was not a climb at all, but only an attempt at the impossible, although, judging from the description of the event in *Motor Cycling and Bicycling*, any failure in the realisation of fact about the climb was more than compensated by the reality of the hill itself. This is how the American report conveys to the reader the fact that the hill was rather on the steep side:

"This Hill it was a Hill."

"If Capistrano could be dug up and transplanted in Kentucky, some gink with a million dollars would beneficently construct a cog-wheel railway up to the top so's the inhabitants could get a view of the Gulf of Mexico. See here—this hill I'm talking about is so steep that a coyote's legs would have to be twice as long on the downhill side as they were on the uphill side in order that this coyote I'm talking about could travel around this hill—sideways.

"Capistrano Hill starts practically at the roadside. From there it mounts upward in a graceful curve, of the order parabola, and finally sweeps into tangency with the hypothenuse of a 37° triangle, near the top. 37° is 75%. And a 75% grade is a grade with a rise of 75ft., vertically, in every 100ft. horizontally. If you understand what that means, you're that much better educated than somebody else who don't understand what that means. Anyhow, by this time, you're beginning to realise that 'this here hill' is some hill. And that's precisely the information I've been tryin' to pound out of this typewriter.

"Subtract one from ten thousand. Then the remainder is the number of people who witnessed this year's motor cycle bombardment of San Juan Hill."

One of the competitors on a steep portion of the slope. Some idea of the steepness can be gathered from the photograph, which is not faked as to its angularity. (*Inset.*) A remarkable photograph of a machine which did a somersault backwards.

Results (?)

Details of the event are not given—presumably the scribe was too occupied with making sure that none of his readers should overlook the fact that "this here hill" was a hill. The illustrations we reproduce show that some of the competing machines had weird and wonderful gripping apparatus clamped to the rear wheel, and the result of these fittings was the churning up of the hill surface—there is no made road up the hill—to such an extent that the motor cycles soon embedded their back wheels in the ground, and not only became helpless, but made the path impassable for those to follow. The result of the event—which can only be conjectured among the mass of Americanese in which the meeting is described—appears to have been that none of the machines succeeded in climbing the hill on the marked out track on account of its churned up surface, but that, after the official event was over, four machines climbed the hill along a path parallel to the official one where the surface had not been churned so severely.

What do our readers think of it all? We must confess for ourselves that, what with the coruscations of the language and the "tractors," we feel somewhat befogged.

Occasional Comments by "Ixion"

The Answer is a Lemon.

I SEE a query in a recent issue about the "suction" which the descending piston exerts on the carburetter. A Service acquaintance (an ex-motor cyclist) tells me that one of his worst trials in the M.T. is that he is no longer allowed to talk about suction, and, if the fatal word escapes his lips or pen, his instructors begin to make opprobrious remarks about lemons. He is commanded to talk about "depression," and to inform recruits that the petrol is not sucked out of the jet by the pistons, but pushed out by the petrol in the float chamber, as there is atmospheric pressure on one end of the column of petrol, and a "depression" at the other end. A rose by any other name would smell as sweet: but it is trying work to pick up a new lingo.

The German D.R.?

CAN any D.R. in the B.E.F. oblige us with any particulars about the Hun despatch riders, the only Boche technical corps of which the Allied press gives us no information? Are they riding latest model N.S.U. machines, or what? Singles or twins? What is the specification, and so forth? I am not supposing that we have captured any of them lately, but surely we collared a few during our offensive stunts in the past; and the Hun press ought to contain a little information, if only of a snapshot type. I am still as ignorant as I was in 1914 as to how Fritz's despatch riders are organised, and what their mounts are like. When the R.A.F. bring down a Hun plane, a full technical report is promptly published for the information of the British trade and Services. I doubt whether Fritz can teach us anything about motor cycles, but we should all be interested to know how his queer brain is working in that line. To judge from the deathly silence which has governed this topic since the late autumn of 1914, one would imagine that there were no longer any Boche D.R.'s. I have heard a yarn that Fritz employed tandem-seated Adler cycle cars on the narrow mountain tracks in the Serbian campaign, and since then not a word about his light motor auxiliaries has reached me. Perhaps he has followed a policy popular in other quarters, and copied the Triumph. Has he any Waacs and Wrens and Penguins driving motors for him, and does the haughty Prussian officer ever condescend to sit in a sidecar?

Cowling-in the Engine.

STILL another original suggestion is directly inspired by aeroplane experience. Some of us were conning the first bound volume of *Flight*, and comparing the naked works of the early Wright and Rumpety aeroplanes with the neatly cowled engines and cockpits and fuselages of to-day. From this contrast the talk wandered to the somewhat similar contrast between early Panhard road racing cars and a modern Brooklands flier. Finally, we diverged into motor cycling topics, and somebody asked whether we could not secure actual gains alike in cooling and speed by cowling-in the power unit of a motor bicycle? The 1¼ h.p. Motosacoche achieved this ideal in an unbeautiful way. It is conceivable that the entire "works" of a 3½ h.p. machine might be hidden inside a light cowl formed on quick detachable metal panels. An elliptical opening at the front would collect nearly as great a volume of cool air as impinges on a naked engine, and might distribute it more evenly over the fins than complete exposure allows. Wind resistance would be slightly reduced, if anything. So far as externals go, the machine could be cleaned with a hose, and if a certain amount of dirt penetrated into the cowl it would include very little mud. The additional weight would be negligible. Given an oiltight engine, cleaning of the bristly parts would be merely a matter of dusting.

Sound Design.

I CONTINUE to receive occasional grumbles from resentful inventors whose engines have been turned down by Government experts. Far be it from this dust of earth, as the Babus say, to claim omniscience, and further still to pretend that a British Government is infallible. Let me rather try to smooth ruffled plumage by suggesting that quite a number of features are essential in an engine to which a Government at war can play foster-father: and that several vital factors may be missing in an engine which is, nevertheless, a credit to its papa. For example, such an engine must be—(1.) Easily manufacturable by unskilled labour and on machines of common occurrence. (2.) Adaptable to the national aeroplane programme. (3.) Better than any similar engine already adopted. (4.) Practical in all its details, as well as satisfactory in general outline. I got a Service friend to have one or two investigations made with regard to complaints which struck me as rational, and in each case the official "No!" was demonstrably justifiable.

Why he Loves a Two-stroke.

I HAVE just been interviewing an ardent two-strokist, a motorist with a bigger mileage behind him than most of our readers. I asked him to state for our benefit why he plumped for an engine which is in rather general disfavour. He produced several reasons. It always starts in ten yards without any running or pushing, it fires at walking pace, and it is so light that he can move it about with no more exertion than wheeling a push bicycle. Moreover, he can carry it up steps, or prop it against a wall, or lift it over a kerb with little more effort than it takes to put an umbrella in a hatstand; if anything goes wrong, it is sure to be the sparking plug, so it sets him no problems. Lastly, it is so cheap that he does not mind leaving it out in the wet or neglecting to clean it oftener than once a month, and if he gets tired of it or should happen to "crash" it, he cannot be very badly out of pocket.

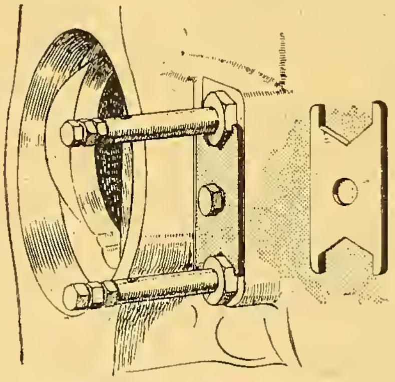
THE RALEIGH ON THE ROAD.

A Short Trial of the Raleigh 5 h.p. Flat Twin and Sidecar.

The new 5 h.p. Raleigh flat twin outfit, with Mr. William Comery, chief engineer of the Raleigh Cycle Co. and designer of the machine, in the saddle.

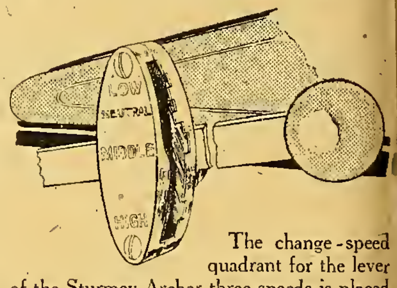
THE space at our disposal last week permitted us to touch only somewhat briefly upon the salient points of the Raleigh flat twin, the engine of which we illustrated on April 11th last. Such unimportant details as the colour of the enamel had perforce to remain unrecorded, but we may say here that the finish of the machine was decidedly neat and attractive. The tank, by the way, is *not* cylindrical.

The engine is rated nominally at 5 h.p., but, as is usually the case, the nominal power falls far short of the actual. The object of the designer was, we understand, not so much high speed and colossal revolutions as a thoroughly flexible and controllable engine capable of propelling either a solo machine fast enough for any road work or a sidecar outfit for general touring purposes.



A neat method of fixing the valve tappets.

The experimental machine was geared for sidecar work, the ratios being 5½, 8, and 13 to 1 approximately; therefore a speed of 50 m.p.h., of which the machine is easily capable, means that the engine is turning over at 3,580 r.p.m. As an example of its flexibility we were assured by Mr. Comery that the machine had ascended a certain hill in the neighbourhood of Mapperley at 10 and also at 40 m.p.h. both on top gear and ridden solo. At first w thought the slow speed the more wonderful, for th hill had a gradient of 1 in 6, but after w had seen and climbed the hill, had noted its extremely rough surface and the nasty angle by which it is approached, and, further, the right-angled corner at the top, we were at a loss to say which performance was the more meritorious, for the faster speed shows enormous powers of acceleration.



The change-speed quadrant for the lever of the Sturmey-Archer three speeds is placed against the lower part of the tank.

We have already mentioned that an Amac carburetter was fitted; this, it is interesting to note, departs from standard in one small particular. The Amac carburetter, as our readers know well, is provided with an air scoop, which catches the air as the machine rushes through it and turns it into the air orifice. This is, of course, designed for the carburetter when in the usual position behind the engine. Now on a flat twin the carburetter must be placed sideways, and this scoop will lose some of its effective-

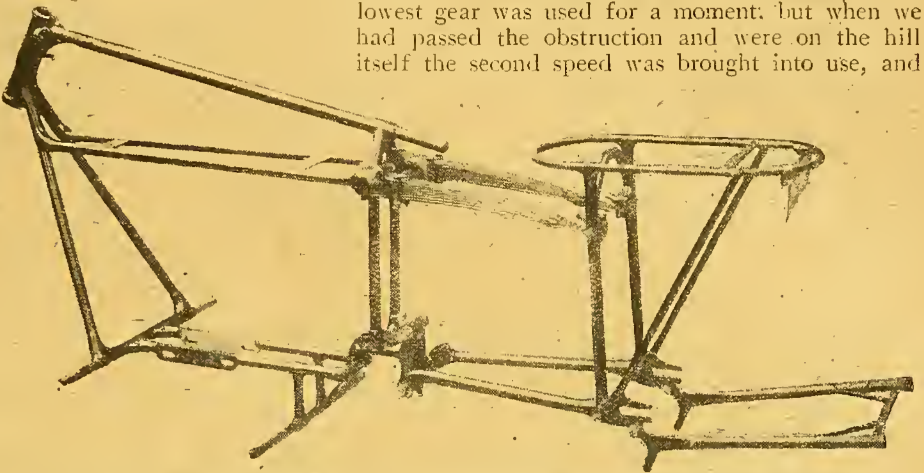
The Raleigh on the Road.—

ness. The centre has therefore been drilled out, leaving a hole about half an inch in diameter. This results in an increased air supply and more power—a fact which does not surprise us, for we are at present using a somewhat old pattern of this carburetter without the air gauze and getting the same results, but the carburetter has become far more sensitive to the position of the air lever, and can no longer be described as semi-automatic. This, however, is only a disadvantage in the case of an inexperienced rider.

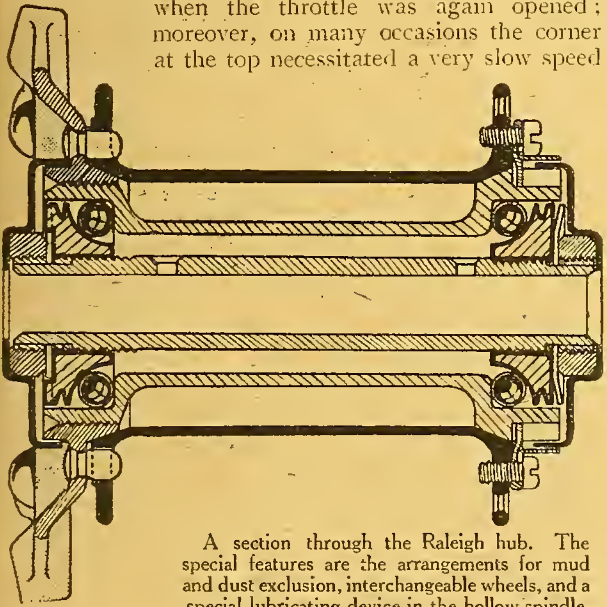
Before describing our trial we ought to mention that most ingenious arrangements have been made for the fitting of the chain cases, one of which, having to rise and fall with the rear portion of the frame, slides over the other, while a felt ring interposed between them excludes dirt, retains the oil, and prevents noise.

We had no need to go far from Nottingham to give the machine a thorough test in all save reliability, for the suburbs of that town abound with steep hills—not very long certainly, but the lack of length is made up for by the sharp corners by which they are approached, and in many cases by the roughness of their surfaces.

During our test we were very favourably impressed by the sweetness of running and wonderful flexibility of the engine, to which we have already referred. The sidecar fitted to the Raleigh was, for testing purposes, intentionally on the heavy side (160 lb.), but in spite of this the steepest hills (several of these have an incline of 1 in 6) were climbed with ease on second speed, and the engine had no difficulty in slowing for a sharp corner and accelerating rapidly when the throttle was again opened; moreover, on many occasions the corner at the top necessitated a very slow speed for the last few yards; the steady slow pulling was then delightful, and, in fact, more like that of a steam than a petrol engine.



The framework of the new Raleigh has double straight tubes throughout, with the exception of the top tank tube. It will be observed that the pivot carrying the rear part of the frame is situated as close as possible to the chain sprocket.



A section through the Raleigh hub. The special features are the arrangements for mud and dust exclusion, interchangeable wheels, and a special lubricating device in the hollow spindle.

Acceleration on Hills.

As we approached the steepest climb of all (a bit of 1 in 5.9), we found the way blocked at the lower corner by two carts and several children; and the lowest gear was used for a moment: but when we had passed the obstruction and were on the hill itself the second speed was brought into use, and the engine accelerated all the way up until the usual corner at the top required a reduction in speed. Turning round, we descended this hill at a gentle pace, an excellent test for the brakes. *We* did not test the pulling power of the engine *down* the gradient.

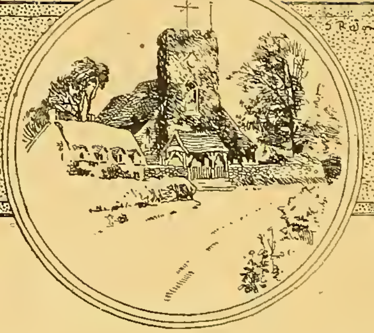
The machine was very quiet and possessed a good turn of speed—circumstances did not permit of this being much used—but what impressed us most was the remarkable flexibility. We ascended long slopes in a powerful rush and crept round corners all on top gear.

A Brooks B170 saddle, combined with the rear springing and Brampton forks, made the Raleigh motor cycle a most comfortable mount to ride, and the sidecar was in no way behind any of which we have had previous experience. We referred just now to reliability—that this is in no way lacking is proved by the fact that the engine has been running for fourteen months without any spares; in fact, no spares for this engine are in existence.

After this pleasant experience we are looking forward to a more extended trial, and also to a test of the machine as a solo mount.

TWO-STROKE ENGINES AND THE GARAGE HAND.

Practically all garage hands are well posted on four-stroke engines. It is only natural, perhaps, that these men assume the same degree of knowledge concerning the two-stroke. Usually, when a two-stroke owner calls at a garage to have some trouble remedied, the repair man goes serenely ahead. He does not realise that, owing to the fundamental difference in the principles of operation between the four-stroke and two-stroke, each must have its own operating characteristics, which must be carefully considered.



MOTION STUDY AND THE MOTOR CYCLE.

Interesting Facts suggested by W. G. Aston's Article, "Relative Motion," published in "The Motor Cycle on October 11th, 1917.

If my object in writing this article had been to impress the reader with the profundity of my scientific knowledge I might have chosen some such title as "The Kinematics of Motor Cycling." As, however, that is very far from my intention, I think it only fair to warn those numerous readers who are already well informed on the subject of kinematics that I have nothing fresh to tell them. The man whose eye I want to catch is he who is ignorant even of the meaning of kinematics.

Now most of us know something about motion study. We can scarcely have failed to have read of those ingenious American gentlemen who propose to revolutionise industry by showing the workman the very best and quickest way of doing his job, no matter what it may be. With this aim these experimenters have made a careful analysis of the motions required to perform certain operations, and they have produced diagrams representing the exact path traced out by a hammer head when driving a nail, by a golf club when striking a ball, and so on. Although this is not the particular aspect of motion study with which this article is concerned, it is one that is not without interest for the motor cyclist. There are not wanting optimistic scribes who foresee the day when touring motor cycles will sell at £15 or £20; but this state of affairs will only come when outputs of machines are reckoned in terms of great grosses, and when production is approached in that scientific spirit of which "motion study" is a manifestation.

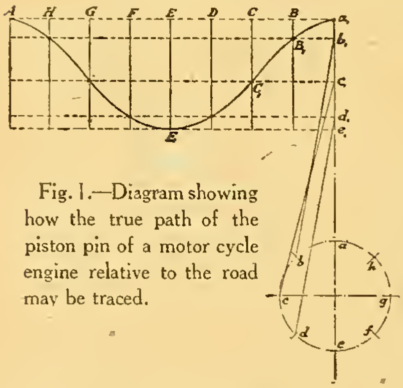


Fig. 1.—Diagram showing how the true path of the piston pin of a motor cycle engine relative to the road may be traced.

The Path of the Piston.

At present our purpose is merely to study the true motion of certain parts of a motor cycle, and for a first example the gudgeon pin of a single-cylinder machine may be taken. When the motor cycle is at rest, with the engine running but declutched, the piston pin travels up and down in a straight path. But as soon as the clutch is let in and the machine moves off along the road the pin now has a motion compounded of its original reciprocating movement and the horizontal travel of the whole motor cycle. It is not difficult to trace the precise path or "locus" of the selected point under these conditions. Assuming the gear ratio to be eight, and the wheel diameter to be 26in., then for each revolution of the engine-shaft the road wheel will make one-eighth of a revolution—that is, the horizontal travel of the motor cycle will be $\frac{3.1416 \times 26}{8} = 10.2\text{in.}$ In the diagram, fig. 1, this distance of 10.2in. is represented by the line a_1 A, while the vertical line $a_1\ e_1$ represents, to the same scale, the stroke of the piston. The crank pin circle a, c, e, g is divided into, say, *eight equal parts, and line a_1 A is subdivided correspondingly. The points b_1, c_1, d_1, etc., give the positions of the piston pin corresponding to the appropriate positions of the crank pin.

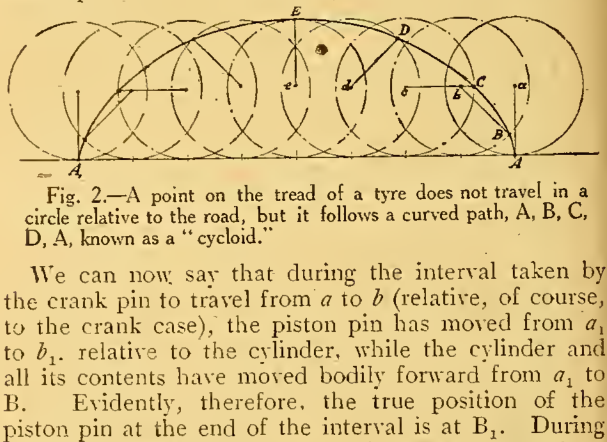

Fig. 2.—A point on the tread of a tyre does not travel in a circle relative to the road, but it follows a curved path, A, B, C, D, A, known as a "cycloid."

We can now say that during the interval taken by the crank pin to travel from a to b (relative, of course, to the crank case), the piston pin has moved from a_1 to b_1 relative to the cylinder, while the cylinder and all its contents have moved bodily forward from a_1 to B. Evidently, therefore, the true position of the piston pin at the end of the interval is at B_1. During the next interval the piston pin moves through a vertical distance equal to $b_1\ c_1$, and through a horizontal distance B C; hence, its real path is along the line $B_1\ C_1$. In a similar manner we can obtain other points on the curve, and eventually the line a_1, C_1, E_1 A is produced, which is the required path of the pin. The sequence of operations is repeated during succeeding revolutions of the engine, with the result that the locus takes the form of a sinuous curve of the type shown to a smaller scale in fig. 3.

A Rolling Wheel.

Another locus that it will be interesting to trace is that of a point on the tread of the tyre. Let us choose the point A, fig. 2, which is shown in contact with the road surface. After one revolution of the wheel this point again touches the road, at A_1, and the horizontal

---

* It is merely a coincidence that the number of divisions, eight, should be the same as the gear ratio.

Motion Study and the Motor Cycle.—

distance from A to A_1 is equal to the circumference of the tyre = 3.1416 × 26in. = 81.7in. Dividing this distance into equal spaces, say eight, we see that the points *a*, *b*, *c*, *d*, etc., represent the successive positions of the centre of the wheel for each eighth of a revolution. In the initial position of the wheel the spoke *a* A is vertical. After one-eighth of a turn the centre of the wheel is now at *b*, and the spoke assumes an angle of 45°. Its outer end will therefore be at B. Similarly, after a quarter of a turn the wheel centre is at *c*. The spoke will have turned through a right angle, and the selected point on the tyre will be at position C. We thus obtain the curve A, C, D, E, A_1 as the locus of the point in question. The mathematical name for this curve is the "cycloid."

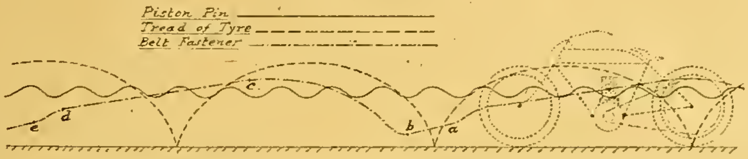

Fig. 3.—This diagram shows correctly to scale the exact paths traced out by the piston pin, a point on the tread of the tyre and the belt fastener.

Movement of the Belt Fastener.

When we come to consider the real motion of a point on the belt, say the belt fastener, the results are rather extraordinary. The method of plotting the curve is too long to be given in detail here, though the principles involved do not differ from those already used. The chain-dotted curve in fig. 3 gives the approximate form of the locus of the belt fastener for a single-geared machine having a gear ratio of 5. The straight portion *a b* represents the true path, relative to the road, of the fastener while it traverses the distance between the engine pulley and the belt rim. From *b* to *c* the fastener is actually passing round the belt rim, while the straight portion *c d* of the locus corresponds to the period during which the belt fastener passes from the belt rim to the pulley. The double curve *d e* is caused by the passage of the fastener round the engine pulley.

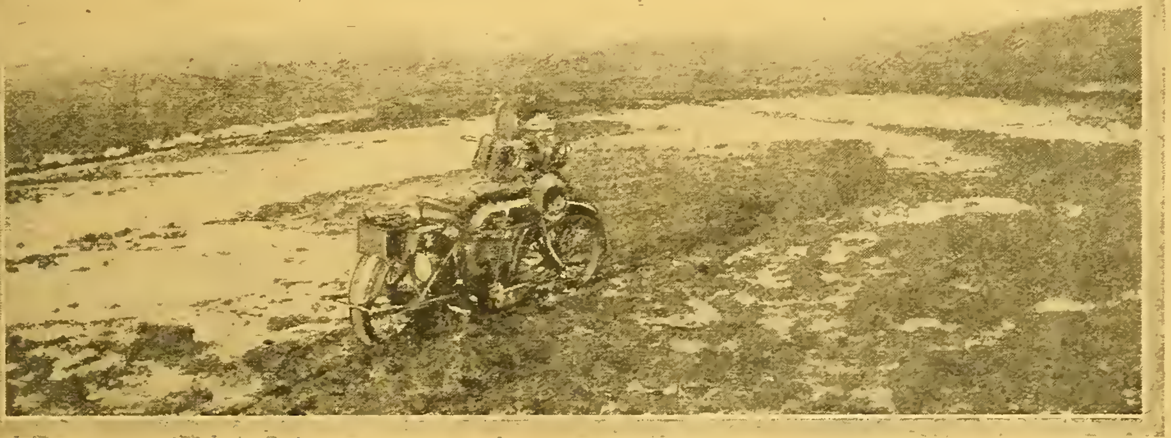
Periodicity.

The three curves in fig. 3 are all drawn to the same scale as the motor cycle which is represented as generating them. Since, in this case, the gear ratio is taken as 5, instead of 8, as in fig. 1, the full line curve traced by the gudgeon pin is somewhat flatter than the one drawn in fig. 1. In comparing the loci in fig. 3, it is interesting to note the variations in what may be termed the periodicity of the motions represented. The engine-shaft makes five revolutions for one turn of the road wheel, hence the piston curve exhibits five undulations for each complete cycloid generated by a point on the tread of the tyre. The "wave length" of the belt fastener path—that is, the distance from *a* to *e*—is the longest of all.

Variations of Speed.

As for the actual linear speeds of the selected points along their respective paths, it may be said that the piston pin attains its maximum speed at about the point C_1, fig. 1. The value of this speed will be in the region of one and one-third times the forward speed of the motor cycle, the precise figure depending upon the gear ratio. When the piston is at the top or bottom of its stroke the speed is, of course, identical with that of the whole machine. A point on the tread of the tyre undergoes very violent fluctuations of speed. When in such positions as A and A_1, fig. 2, the point is absolutely at rest, whereas at position E its velocity is just double that of the motor cycle. The varying speed of the belt fastener can easily be seen by comparing the straight portion *a b* of the path with the part *d c* (fig. 3). The fastener takes the same time to traverse two distances, one of which is four times as great as the other.

MOHANDIS.

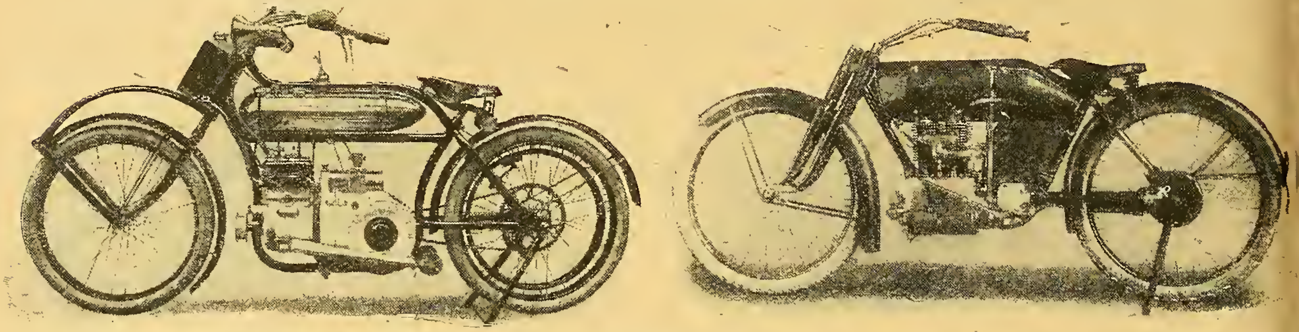


It would be hard to conceive a more desolate and sullen landscape than the one reproduced. The solitary riderless motor cycle sunk in the mud only adds to the melancholy of this Macedonian scene, and, incidentally, shows that the life of the D.R. in that country is not altogether a bed of roses.

THE SIDE-BY-SIDE TWIN ENGINE.

Some Observations on Engines in General and the "Vertical" Twin in Particular.

Excepting those that have the two-stroke type of engine, there are no motor cycles on the market to-day that are fitted with side-by-side two-cylinder engines. Yet this type of power plant offers certain advantages over other types more favoured by motor cycle engineers. As will be seen from this article, quite a number of "vertical" twin engines have been made, and undoubtedly brief particulars concerning them will be read with interest by those of our readers who have not followed the evolution of the motor cycle to its present stage, while to the younger generation it may come as a surprise that such engines have been designed, built, and forgotten.



(Left) The 1913 Morse-Beauregard, an American vertical twin with integral gear box and shaft drive. (Right) The Herdtlé-Bruneau, a French production.

WHY has the "vertical" two-cylinder apparently received such scant attention on the part of motor cycle designers?

This is a question often asked by present-day motor cyclists when discussing motor cycle engines, while to light car owners, who have owned small cars fitted with this type of engine, the question is a greater mystery.

Unfortunately, the "vertical" twin has not been sufficiently developed to allow a motor cyclist to judge its merits in comparison with the V and flat twins and singles. Even in the vertical twin two-stroke type there is only the Scott which is known to a number of riders. The engine of this machine has side-by-side cylinders, and is placed in the frame in an inclined position, therefore is not, strictly speaking, a "vertical" twin. However, for the purposes of this article, it is sufficient to class both inclined and vertical engines together as the side-by-side type. The Allon and the Premier twin two-strokes were introduced only just prior to the war, and their *début* as marketed machines has been postponed.

However, every rider of a Scott will confirm that, on the point of balance, this vertical twin offers very decided advantages over the V twin.

I have had considerable experience with all types of engine in every kind of vehicle, but the only branch of motoring in which I can find all types of engine likely to be fitted to motor cycles is that of the light car. Obviously it is desirable to compare engines working under similar conditions rather than to attempt to draw conclusions from experience with, say, a six-cylinder Rolls-Royce on the one hand and a lightweight motor cycle on the other. Hence, my mind travels back to experiences with light cars, and I have no hesitation in placing the various engines in the following order:

1. Six-cylinder vertical.
2. Four-cylinder vertical.
3. Two-cylinder flat, 180° cranks.
4. Two-cylinder vertical, 180° cranks.
5. Two-cylinder 90° V, single throw cranks.
6. Two-cylinder 90° V, 90° cranks.
7. Two-cylinder V 60°, single throw cranks.
8. Two cylinder vertical, single throw cranks.
9. One-cylinder.

The six-cylinder vertical engine can be ruled out as a type outside the present scope of the motor cycle. The four-cylinder engine, I am convinced, will eventually be regarded with favour in this country, but for the time being anything over two cylinders apparently does not interest the motor cycle designer.

In the two-cylinder group we have six different types, among which the flat twin certainly leads. With this type of engine we have excellent balance, combined with even firing. The 90° V engine comes next, because it is possible to balance an engine of this type perfectly in every way; indeed, in this

The Rochet motor cycle, with neat engine-gear unit and chain drive—a 1905 production.

spect it is superior even to a four-linder vertical engine.

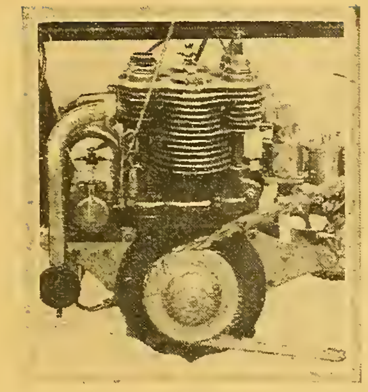
It will be noted that in scheduling y impressions of engines in light cars he two-cylinder vertical type with 180° ranks is placed before the 90° twin. his is due to the fact that there have een more suitable engines of the former ype for light cars than those of the tter—at least, that has been my xperience.

In the vertical two-cylinder engine ith a single crank pin the balance is o better than in a single-cylinder engine, nd the designers have obtained even ring at the expense of good balance.

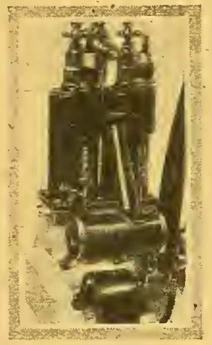
Balance and Firing Torque.

When an engine is running at a speed f 1,000 r.p.m. and over, the question of iring torque becomes insignificant when ompared with that of balance; indeed, ne notices very little difference in this espect among all the two-cylinder types xcept when they are running slowly.

The two-cylinder vertical engine with 180° cranks is certainly superior on many points to the conventional 60° twin, and since the flat twin and the 90° engine are not favoured by certain designers one cannot understand why the 60° twin is chosen instead of the vertical type which is superior to it. This may have been due to the gradual development of the motor cycle from the original motor-assisted cycle. The transmission was an easy matter while it was only necessary to connect up the engine with the rear wheel by means of a belt; consequently, the crank case dimensions of the single-cylinder engine were retained when a two-cylinder engine was introduced. The evolution of the motor cycle has been largely governed by the manufacturers' tendencies to follow the line of least resistance. One can quite understand this when it is considered that for many years the development of the engine alone was a problem quite big enough without the designers introducing what they may have considered side issues such as new transmission systems. Maybe, this method of development of separate units has not been so successful as one would have been in which the complete motor cycle had been taken as a whole. In the car world the latter was the case, with the result that, although the motor car evolved from the horse-drawn carriage, there is not a single point in a modern motor car following the practices of the parent vehicle. The same cannot be said of the motor cycle. It commenced as a motor-assisted bicycle, and bicycle practice is still in evidence at many points.

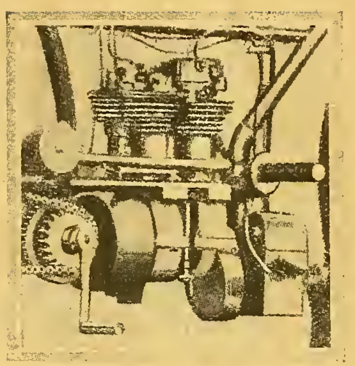


The Bercley of 1905—a side-by-side twin placed across the centre line of the frame.



A 1908 L.M.C. engine.

We think that had designers considered the machine as a whole there would have been more vertical twin engines, and probably four-cylinder engines also; but, in this case, it is only of recent years that the small capacity cylinder has been made nearly as efficient proportionately as the larger engine.



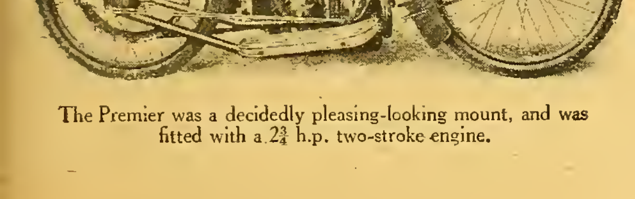
The Moto-Rêve vertical twin built in 1909.

It may be recalled that when the little four-cylinder Singer light car was introduced to the motoring world by *The Motor Cycle* it was ridiculed. Its small cylinders were likened to bicycle pumps, and very few thought that such an engine would prove to be more effective for its purpose than a two-cylinder with cylinders of double the capacity.

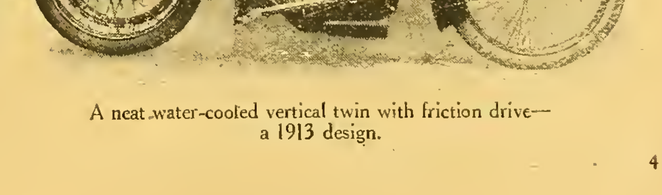
Vertical Twin Experiments.

The vertical two-cylinder engine with 180° cranks has several points to recommend it. It is excellently balanced, it is compact—a most important point where motor cycles are concerned—and it can be made more accessible than any other type of engine, excepting the single. Its only drawback is its very irregular firing torque, two explosions taking place during one revolution and one in the next.

Quite a number of motor cycle concerns known to present-day riders have experimented with vertical twins in various forms. The Scott Co., Alldays and Onions, and the Premier Co. introduced side-by-side two-stroke engines, while the Rudge, Singer, Centaur, Quadrant, L.M.C., Triumph, and A. J. Stevens concerns have made twin vertical four strokes. The Rudge engine was just an adaptation of two $3\frac{1}{2}$ h.p. single-cylinder units placed side by side in a motor cycle frame. The Singer effort was a similar combination adapted for an experimental belt-driven cycle car. The Quadrant, too, was only an adaptation; but the

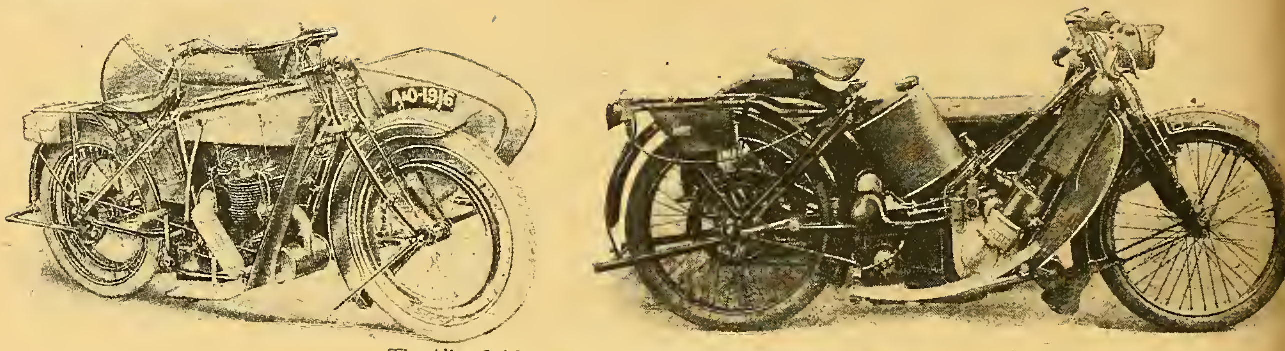


The Premier was a decidedly pleasing-looking mount, and was fitted with a $2\frac{3}{4}$ h.p. two-stroke engine.



A neat water-cooled vertical twin with friction drive—a 1913 design.

The Side-by-side Twin Engine.—



The Allon 5-6 h.p. and 3¾ h.p. Scott two-stroke sidecar outfits.

Centaur, L.M.C., and Triumph were serious attempts to produce a vertical twin engine for motor bicycle work, while **the A. J.** Stevens engine was used for tricars.

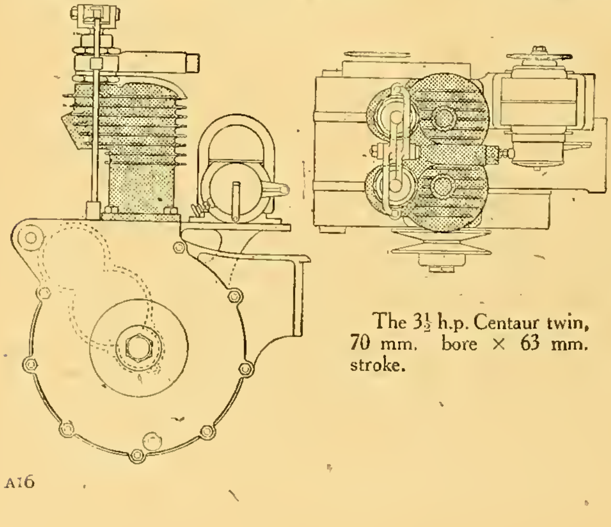
As far back as 1903 a French racing machine was fitted with a 14 h.p. vertical twin air-cooled engine. In 1904 the Stevens engine was introduced, and also the Werner 4 h.p. engine with cylinders 60×76 mm.

Various Twin Designs.

In 1905 there were the Bercley 5 h.p. 70×80 mm. engine and the French-made Rochet motor cycle. The Bercley engine appears to have been favourably received by several motor cycle manufacturers, for in 1906 and 1907 the Royal Consort and the Onaway machines were fitted with it.

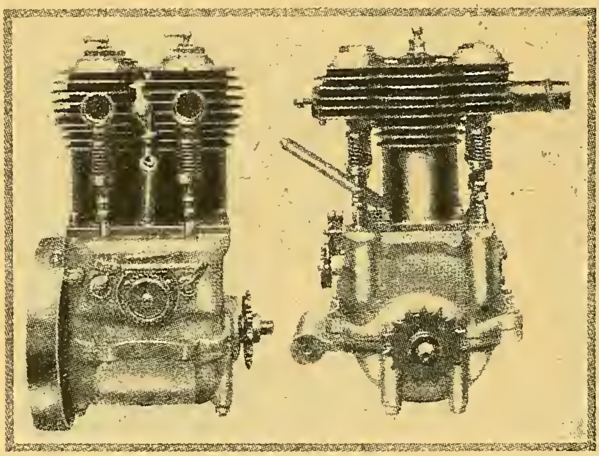
In 1908 the L.M.C. was introduced, followed by the Moto-Rêve in 1909, and the Alcyon in 1911.

During 1910 the Centaur Co. experimented with a small vertical twin-engined motor cycle, which was a very nice little machine in many ways. The air-cooled cylinders were cast *en bloc*, and had mechanically operated overhead inlet valves. The bore and stroke were 70×63 mm. respectively, and the engine occupied space in the frame approximating to that of a conventional 3½ h.p. single-cylinder engine.



The 3½ h.p. Centaur twin, 70 mm. bore × 63 mm. stroke.

In 1912 Mr. B. H. Davies—who is well known to readers of *The Motor Cycle*—suggested a specification for an ideal motor cycle which included a vertical twin engine, and 1913 saw a Triumph engine on the road in an experimental form, but it never reached the marketing stage.



The Triumph vertical twin which, at the time it was described (1913), created great interest.

The Triumph engine was a most interesting design, embodying a worm-driven camshaft across the crank case between the 180° cranks, which carried cams at each end. The cylinders had "T" combustion heads — an unusual practice even in the car world, the engine of the Baby Peugeot small light car being one of the few which embodies it. In small cylinders, however, the "T" head offers the advantage that comparatively large valves can be used, and for this reason it was favoured by motor cycle engineers, who in multi-cylinder engines are called upon to work with smaller dimensions than their brethren in the large car field. The Triumph, probably, is the most interesting motor cycle engine of the side-by-side four-stroke type which has been made, and, as is apparent from examination of the pictures illustrating it, it was a most carefully thought-out design. I understand that this machine is still on the road, although the makers, in their very sound policy of concentration, appear to have abandoned their experiments.

The American M-B machine appeared about this time, and also another French production—the Herdtlé-Bruneau.

Suitable for Shaft-drive.

Of late years, however, no effort appears to have been made to develop this type of engine, excepting in the two-stroke class, but should shaft transmission become popular the vertical twin will be more suitable than either the flat or V types.

Much depends also on the development of the two-stroke cycle, as an engine of this type with side-by-side cylinders and 180° cranks is equal to a four-cylinder on points of balance (the couple excepted) and firing torque. If the two-stroke is eventually made equal in overall efficiency to the four-stroke, the side-by-side engine certainly is a type of the future. But even if no more are made, this article renders service to motor cycle history.

THE RALEIGH ON THE ROAD.

AN ELECTRIC MOTOR CYCLE.

Municipal Road Repairing Methods.

We have before us a specimen of road material, which appears to be broken furnace slag. It has been freely scattered on suburban Birmingham roads during the past week-end, presumably by the municipal authorities, but for what purpose is not apparent.

The road mentioned to us is one of dry, bone-hard, tarred surface shaded by trees, so that there can be no question of absorbing a sticky or newly tarred surface. Furnace slag breaks up into something very nearly akin to broken glass. The pieces were picked up haphazard, and vary from ¼in. knife-like splinters to 2½in. lumps, each a mass of large points and sharp edges.

As evidence of the destructiveness to tyres, we have been shown no fewer than sixteen splinters picked out of the tread of a nearly new Dunlop 1½in. cycle cover after it had traversed the surface for one hundred yards. Fortunately, only one has penetrated enough to cause a slow puncture.

These points stand out: (1) The absurd type of material, (2) needless waste of labour in these days, and (3) the total disregard for the convenience of cyclists and motorists, to say nothing of pedestrians.

Some Sparks.

It is said—we cannot hold ourselves responsible for the truth of the rumour—that there is in existence a magneto capable of giving 45,000 sparks per minute. Can any reader confirm?

A Presentation.

At a gathering which followed the annual general meeting of the British Ignition Apparatus Association last week, Mr. Ernest Garton, who has acted as hon. secretary of the association from its inception, was entertained at dinner by the members, and presented on their behalf by the chairman, Mr. Peter F. Bennett, with a token of appreciation and thanks in the form of a very handsome grandfather clock.

Officials of the A.B.M.A.M.

The following are the present chairmen and vice-chairmen of the various sections of this association: Section of Private Car Manufacturers—Chairman, Mr. E. Powell (Humber); vice-chairman, Mr. L. Walton (Vauxhall). Commercial Vehicle Section—Chairman, Mr. H. C. B. Underdown (Commercial Cars); vice-chairman, Mr. F. Churchill (J. and E. Hall). Motor Cycle Section—Chairman, Mr. J. W. Stocks (Components); vice-chairman, Mr. C. A. Hyde (B.S.A.). Accessories and Components Section—Chairman, Mr. Bernard Caillard (British Lighting and Ignition Co.); vice-chairman, Mr. H. Johnson (Lucas).

Petrol Consumption.

In a recent petrol consumption trial at Hamilton, Ontario, the rider of a Henderson used only three and a quarter quarts of petrol for a journey of ninety-eight miles. This is equivalent to the rate of 121 m.p.g. The rider was a private owner and did not use any extra fittings on his machine.

Another owner rode a Harley-Davidson, and used five and a quarter quarts for the same distance. Another Henderson, to which was attached a sidecar, covered the ninety-eight miles on six quarts.

Formation of a New Club in South Africa.

A new motor cycle club has been recently formed at Jansenville (South Africa).

Patents.

How many of our readers interested in patents are aware that a German can—or could until recently—ensure protection for his invention in England? Have any English patentees tried to obtain patents and secure royalties on their ideas to take effect in Germany in war-time?

A 400 Miles Trial in Natal.

A trial run from Durban to Ladysmith and back was recently held in Natal. Out of nineteen starters, only six finished, and out of the six five rode Harley-Davidsons. Doubtless, owing to the war, England was represented by only four machines, and all the other competitors rode either Indians or Harley-Davidsons. The winner was Spargo (Harley-Davidson sidecar).

Hill-climbing in America.

The trade organises the hill-climbs in U.S.A., and a freak hill usually is found which is very difficult to surmount. At a recent big event, the course was 500 feet, and no competitor succeeded in reaching the top, the prize going to the man who covered the greatest distance. The official announcement of the results mentions, besides the make of the machine, the names of the makers of the tyres, magneto, saddle, etc.

A Bomb for F.N.

According to *Les Nouvelles*, the British air raid on Liège caused a considerable amount of damage, and it is reported that a bomb was dropped upon the National Arsenal, which is now controlled by Germans. This is the famous Fabrique Nationale d'Armes de Guerre, our old friends the makers of the F.N., whose workpeople made such a gallant resistance when the Germans first entered Liège, and whose women employees poured boiling water on the Huns.

A.C.U. Messenger: Woolwich Police Summons.

At Woolwich Police Court on Friday, Albert Thorne, of Blackheath, was summoned for exceeding the speed limit at Eltham, for using an unregistered motor cycle, and improper use of petrol or substitute. P.C. Oldfield said the speed was 42 m.p.h. When asked if he was in the Army, defendant, who was in semi-military uniform, replied, "I am on Government service," and produced a petrol permit, saying he was employed for two days a week as a messenger between the G.P.O. and W.O., and was testing the motor cycle when stopped.

Fine and Costs for a Volunteer.

For the defence, it was stated that Thorne was a member of the Auto Cycle Union's Motor Messenger Detachment that provides the volunteer messengers for the W.O., and on two days a week the petrol was supplied him. On this occasion he was testing the motor cycle (that he purchased a week before) to see if fit for service. Fined 20s. for first offence, 10s. for second, and third dismissed with costs.

Four-inch Tyres.

A writer in a contemporary suggests 4in. tyres in lieu of spring frames. The early Pennington machines had small wheels with enormous tyres.

Petrol Engine as Air Compressor.

The quaintest use to which we remember seeing a motor cycle engine put is that evolved by a resourceful repairman in the South of London. Not so long ago we noticed a veteran 2 h.p. Minerva perched oddly among the overhead shafting. The proprietor (an ex-Navy artificer—perhaps that accounts for it!) had connected it up to the shaft pulley with a flat belt, filled the crank case with oil, and was using the unit to pump air through a long length of motor cycle tubing to a section of piping connected to the gas supply, and had thus secured, at the minimum of expense, a strong pressure for a blowpipe.

Keeping Horses.

More than one motorist has probably thought of avoiding petrol troubles by going in for "horseflesh," and the sight of horses used unrestrainedly for joy-riding may have annoyed some motorists, but owning a horse at the present time is not all "beer and skittles." If you cannot feed your motor it will not go, and there is an end of it; but in the case of a horse the matter is different, and many a horse owner has for long been at his wits' end as to where the next meal for his friend is coming from. It is not pleasant to think you are starving a hard-working beast to death, or giving him so little food, bought at a fabulous price, that he cannot be expected to work, and so is costing much money and giving nothing in return for it.

This is where the motor does score.

The United Arts Rifles.

During the Whitsun week-end a very pleasant and interesting day was spent in the country in field and road sketching operations by the Motor Squadron of the United Arts Rifles, for the instruction of members on how to read and draw a map. This kind of work will be carried out by the 1st Battalion (United Arts Rifles) County of London Volunteer Regt. during the summer months. The accompanying photograph of the left wing of the Motor Squadron shows part of a turn-out on a recent Sunday parade.

Fuel for the Summer!

It is surprising how hard some rumou die. We are still being asked if we ca say if there is truth in the rumour tha petrol—or at least a certain amount of i —is to be released for joy-riding thi summer. Unfortunately there is not.

Tyres.

So many pre-war machines have bee laid up that when motor cycling is agai permitted as a pastime there will be considerable demand for tyres to re-equi them. Will tyre manufacturers mak tyres suitable for the old type rims, a in 1914 the tyre and rim standards wer altered?

Air Cooling.

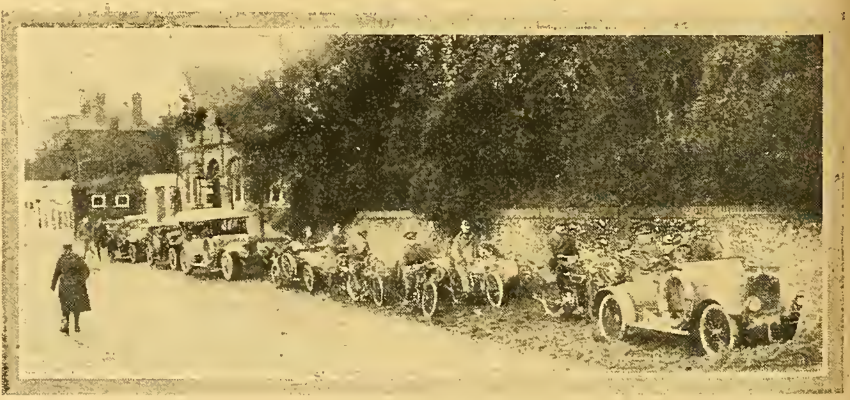
The Franklin system of air-cooling (drawing air down vertical fins on the cylinder by means of a fan on the flywheel) is being used on engines for a variety of purposes. Electric lighting plants and other auxiliary engines are a great deal less trouble to maintain when they have no water jackets, besides being more economical in fuel.

To Meet War Office Requirements.

One of the post-war J.A.P. engines (the 8 h.p.) was recently submitted to a very severe test by its makers, to meet War Office requirements. It was run continuously for seven days and nights with a load of 12 h.p. at 1,800 r.p.m. During the whole of the test the engine did not need the slightest attention, nor show any signs of loss of power. When the engine was dismantled after the test careful examination failed to show any trace of wear.

Repair Work.

Yielding to domestic pressure, and touched by the trust shown in our omniscience in matters mechanical, we took our player piano to bits the other day. These are interesting beasts to dissect: it is instructive to put on a Scherzo and see the revolutions they are capable of. It is marvellous how such a flimsy contrivance of wood and fibre bearings, tiny brass driving chains, canvas bellows, and skimpy controls stands up to its work. The thing is as much of a "running miracle" as Kipling's steam car in that motoring classic "Steam Tactics." (Do you remember the raceful of ball bearings "strewn four miles along a Hampshire road," and recovered in detail?)



The left wing of the motor squadron of the United Arts Rifles, County of London Volunteers.

THE MOTOR CYCLE

AVIATION SECTION

The enormous importance of the Air Service needs no emphasis; it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National Service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouragement of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

The New Role.

Three former motor cyclists now on he headquarters staff of the Air Ministry re Majors S. R. Axford, Reginald G. Holloway, and T. G. Baxendon.

Best Quality Petrol!

The best quality petrol is now reserved xclusively for flying purposes. Testing ero engines at manufacturers' works is argely carried out on coal gas.

Money.

How many airmen have any idea as to he cash value of the 'buses they "crash" and play with as toys? The crankshaft of the R.A.F. 4A engine costs something in the neighbourhood of £120! The cost of the average motor cycle crankshaft in pre-war days was about 25s., and that of the Ford car about £3.

The R.A.F. House Magazine.

Still the members of the Flying Service staff await the appearance of the long-promised House Magazine—a production approved by Lord Rothermere, the former Secretary of State. Subscriptions for the magazine were invited and obtained in hundreds some months ago. Why this delay?

An Old T.T. Rider.

In the Strand last week we caught a glimpse of Lt.-Col. H. Lister Cooper, R.A.F. Col. Cooper was a leading motor cyclist in pre-war days, and joined up soon after the outbreak of war, gaining his "wings" quite early in his Army career. He competed in the Tourist Trophy Races and several of the more important long-distance reliability trials, his usual mount being a Tourist Trophy Triumph. A year or two ago he gave Mr. Frank Hulbert, of the Triumph Cycle Co, his first experience of flying in an aeroplane.

AIRMEN MOTOR CYCLISTS

It is with great regret that we announce that Lt. Frank M. C. Houghton, R.A.F., was accidentally killed while flying on May 6th at a Wireless Experimental Establishment. He was twenty-three years of age, and was educated at Magdalen College School, Oxford, and Denstone College, Staffordshire. He left school on August 1st, 1914, and received his commission shortly afterwards in the Shropshire Light Infantry. He then transferred to the Army Cyclist Corps, and in May, 1916, became an observer in the R.A.F., in which force he served continuously for eighteen months in France, obtaining his wings in 1917.

We first made his acquaintance when, having offered his idea of a military motor cycle race meeting at Brooklands to a certain quarter, and receiving no encouragement, he approached us, and *The Motor Cycle* was able to help him considerably, and, with the assistance of the British Motor Cycle Racing Club, Houghton, on being appointed hon. secretary, was instrumental in organising one of the most successful and interesting meetings ever held on the famous track. This was followed by the United Services meeting in the following September.

The late Lt. F. M. C. Houghton, R.A.F.

It was obvious that the Army Cyclist Corps had few attractions for so keen a mechanical enthusiast as young Houghton, and it was only natural that he should transfer to the R.A.F. His favourite mount was a Rudge, on which he competed at the two meetings at Brooklands, and, despite the fact that he became an expert pilot, he always maintained that he found flying exceedingly dull, and much preferred to ride a motor bicycle. Not only was he a clever motor cycle rider, but he had the excellent gift of recording his experiences on paper in a particularly pleasing manner. He contributed several articles to *The Motor Cycle* in an easy, interesting style which was keenly appreciated by our readers, and one of his articles appeared in the issue of May 23rd, under a pseudonym which he had adopted for himself—"Pitot."

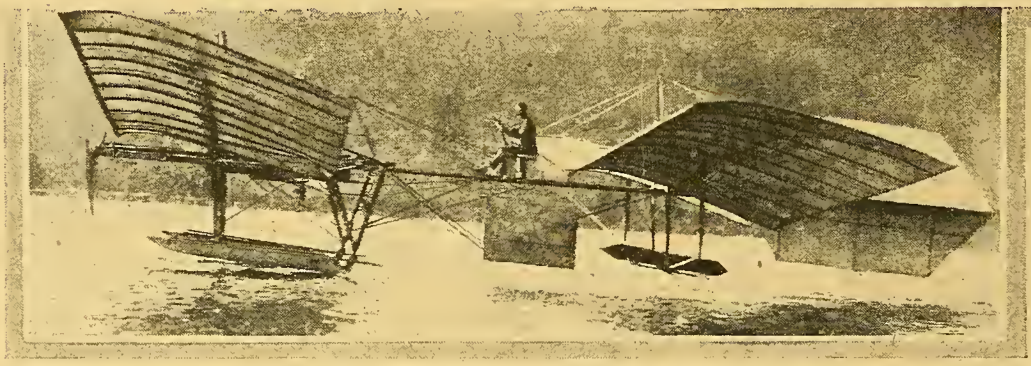
American Aircraft Production.

It is said that our American Ally is to form an Aircraft Production Department, and, as in England, it will be separated from the Army-proper.

Four-engined Bombers.

It is reported that the Germans have raided this country on more than one occasion with bombing Gothas having four engines. Those fetched down, according to published reports, were fitted with two engines.

TRIBULATIONS OF THE PIONEERS



The Langley tandem monoplane, constructed in America in 1902.

Adventures with a Monoplane that was engined with a Radial of 2½ lb. per h.p. in 1902.

"AT fifty miles an hour she nose-dived into the water, taking me under. I was all tied up in the framework, as my cork jacket was caught. I was able to tear loose, and except for swallowing a few pints more water than I calculated for, was none the worse for it!"

The speaker was Mr. Charles M. Manly, one of America's earliest experimenters in aviation, and now testing engineer to the Curtiss aeroplane firm in Buffalo. He had been chatting about the initial attempts at flight which he had made in America with the Langley tandem monoplane back in 1902. From 1896 Professor Langley and Mr. Manly had worked together on this ill-fated machine, in the face of apathy, and often open hostility. It was not until 1916 that their theories were triumphantly vindicated, and the original machine was taken from the Smithsonian Institute, overhauled, and without any alterations, made a perfectly successful flight.

In 1897 Professor Langley, who was connected with the Smithsonian Institute (a sort of combined British Museum and Kew Laboratory), decided to put into effect his long cherished theories about bird flight. His designs were so far approved that the authorities advanced him a sum of £10,000. Moreover, scale models had been made and successfully flown over a distance of threequarters of a mile.

2½ lb. per Horse-power.

The partners commenced work on a full-sized machine. The first difficulty that arose was the attainment of the necessary power within a reasonable weight. In those days engines were cumbrous in the extreme. The twain came to Europe, where they met with scant success. Count De Dion, Napier, and the Daimler Gesellschaft in Germany were all unanimous in saying that the thing was impossible. Discomfited, but undaunted, they returned. The travels of Odysseus and labours comparable to those of Hercules had ended in nothing.

It was here that the quality of the men showed itself. Mr. Manly went to work, and after a little less than a year he had produced an engine, an adaptation from rotary to radial form of another man's unsuccessful idea, which came out at 2½ lb. per h.p. One quarter of the weight originally hoped for, and a figure which even nowadays is reckoned fair.

An Anxious Moment.

Finally, the machine was ready for the trials. The launching was to be accomplished from the top of a cumbrous erection which had been run up on a barge, the pioneers having decided that water would be softer to fall upon. The machine was to be stored in pieces in the barge, and when one of these fine days came, such as Wilbur Wright used to wait for (watching the smoke of his cigarette, and refusing to tempt the Fates if it did not ascend vertically!), when there seemed a fighting chance of success, they would release the big machine down the inclined plane to the water, and see what befell.

Mr. Manly was determined to pilot his weird offspring (a very good idea of her can be gleaned from the photograph, the original is one of the very few in existence), and on a bright December morn the incline was greased, and the word given to "Let go!"

Think of that moment, that was to have crowned years of effort, toil, anxiety, rebuffs, and the cold apathy that is worst of all. If life never held another moment for them, in that one they had certainly *lived*.

The awkward machine began to slither down the slope, and hitched! The release mechanism had failed to work; and thus arrested, the ill-starred craft put her head down and dropped like a plummet, with the effects described in the introductory paragraph.

Nothing daunted, the partners set to work to make good the damage. By this time the money was running low, and at that very time the authorities, in a panic, decided not to sanction a further grant of £4,000 which had been proposed.

Tribulations of the Pioneers.—

The two decided that, at least, they would have one more try—after which they would have to take up something lucrative, and leave the realisation of their dream to others. They patched her and spliced her, and made her ship-shape, until one evening, a little more gusty than they would have chosen if conditions had admitted of further delay, they made the final attempt.

A Second Attempt.

Mr. Manly clambered up into the precarious seat and grasped the controls. The machine slipped downwards, gathering speed. . . .

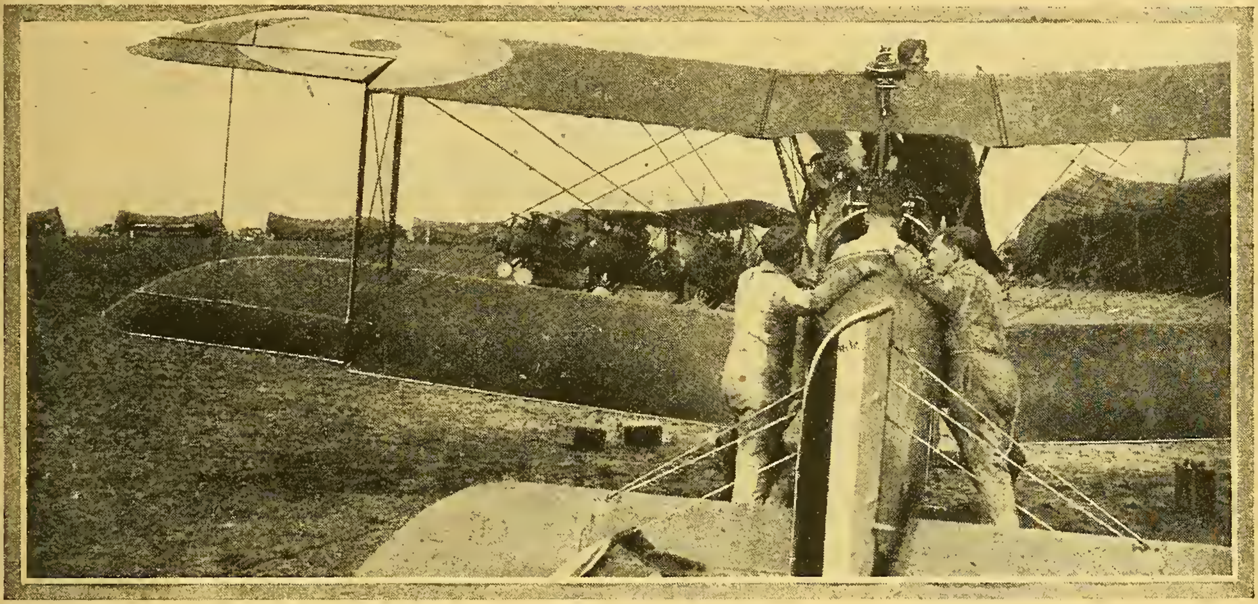
But the treacherous wind chose that moment to buffet the tail of the unwieldy craft, which snapped against the heavy guard rail of the incline. Utterly beyond control, but flying strongly, the machine rose, until it was twenty feet clear of the water, rising almost vertically.

For an instant it seemed that the machine would crash down on the barge, but instead it pivoted, the madly revolving propeller acting for the instant as a helicopter, and dropped, flat on its back in the water.

The saturated and indignant pilot crawled from under the wreck of his hopes, swearing to have nothing more to do with flying machines! (A rash resolution, for few men in America have a more intimate connection with aviation at present than he.)

The remnants were salved, and for years flippant sightseers made derogatory remarks about the machine in the museum where it was housed.

As has been told, fourteen years later it was exhumed, and flew faultlessly. R.H.B.



On the Western Front during the German offensive. An R.A.F. scout being tuned up for a "stunt."

* * *

THE PUZZLE OF THE SEAPLANE.

IT is a little difficult to understand why the seaplane has not died a natural death, and the answer is one of the bits of information which we all hope to receive when the war ends. So long as aeroplanes were grossly unreliable, it was obviously desirable to use machines which could "land" on the water, to commit rather a bull. But the punt-shaped floats of a seaplane, or the hull of a flying boat, add a lot to the weight of a machine, and vastly increase its "passive drag," or head resistance. One would have thought that land aeroplanes would supplant the seaplane and flying boat for overwater work, with the possible exception of districts where smooth waters are available, and where ground suitable for aerodromes is rare: *e.g.*, in the Italian lake district, and possibly round the great lakes of Africa. Yet a few days spent at any of our coastal resorts shows that the seaplane and flying-boat are still much in evidence, though their speed, climb, and carrying capacity are so inferior.

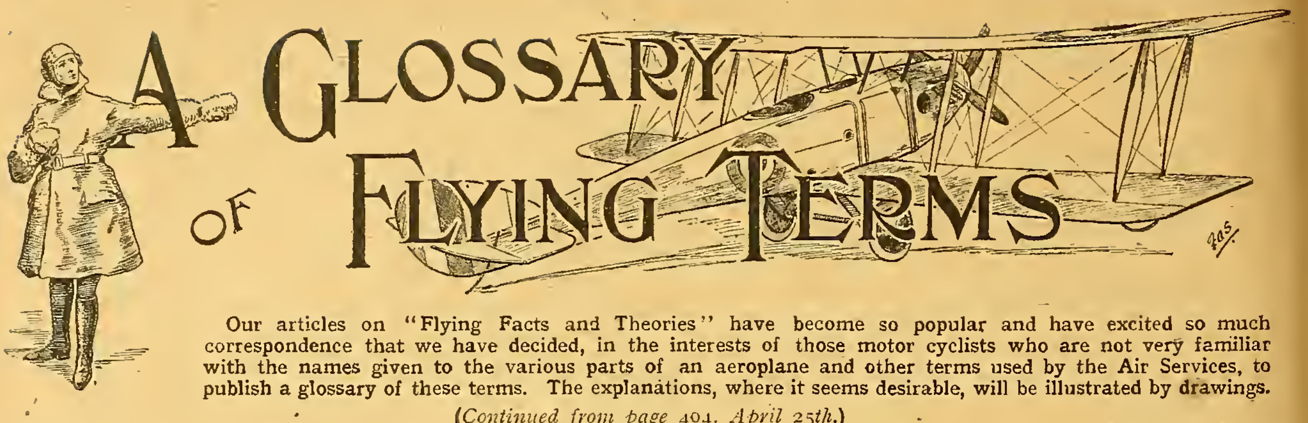
T.

CROSSING THE ATLANTIC.

A TRANSATLANTIC flight is already a technical possibility. Given average luck, any of the giant machines could manage it. Fritz's delay is quite explicable. The Italians, French, Americans, and our own men probably do not regard a mere sporting or technical record as worth while until sterner business is happily concluded. As the prevailing winds blow from the other side, the flight will probably be made in an easterly direction, and the "disthressful" island may witness the final triumphant landing. As the petrol tanks are emptied, they will probably be jettisoned into the sea, being mounted amidships so that their loss would not affect the centre of gravity: but it will hardly be possible to drop any engine which gives trouble, as its sacrifice would ruin the "trim" of the machine. Navigation problems will need careful working out, and if the "landfall" of the Irish coast is not made at the expected moment, the petrol tanks may be getting dangerously empty.

TORQUE.

A GLOSSARY OF FLYING TERMS



Our articles on "Flying Facts and Theories" have become so popular and have excited so much correspondence that we have decided, in the interests of those motor cyclists who are not very familiar with the names given to the various parts of an aeroplane and other terms used by the Air Services, to publish a glossary of these terms. The explanations, where it seems desirable, will be illustrated by drawings.

(*Continued from page 404, April 25th.*)

DOPE.

The fabric employed for covering aerofoils is usually the best Irish linen, which, if used in a natural state, would be imperfect in three leading respects. It could not be made sufficiently taut on the ribs by any mechanical method of stretching. It is by no means weatherproof, and would disintegrate rapidly. It is not airtight, but rather porous under the heavy air pressures involved in flying. As no more suitable fabric has yet been invented, it is necessary to coat the fabric. At one time fabrics were rubberised. Nowadays they are treated with several coats of "dope," followed by further coats of varnish. The dopes and varnishes vary both in the method of application and in their internal composition; but the aims of every coating formula may be summarised as follows: They are intended to contract in drying and make taut the fabric; to dry quickly, and so accelerate manufacture and repair; to be absolutely waterproof; to resist frost, vibration, and sun. Sunproofness includes resistance to heat, and also the use of a pigment to nullify the chemical action of certain light rays. The coating must be flexible, impervious to petrol and oil, and non-inflammable. Certain dopes are dangerous to the health of the "doper," and others—usually less efficient—are not.

DIHEDRAL ANGLES.

A dihedral angle normally means the angle between two planes. In aeronautics two such angles are familiar, which are known as the lateral and longitudinal dihedrals respectively.

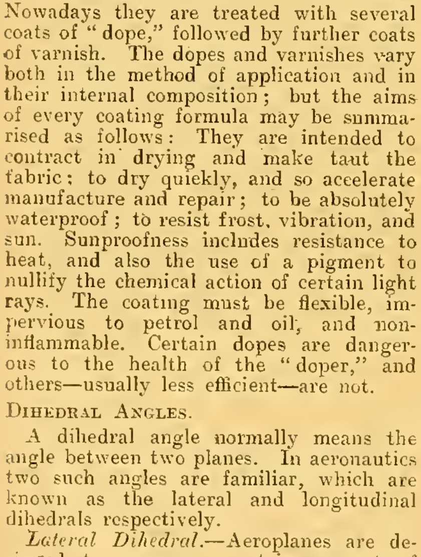


Fig. 1.

Lateral Dihedral.—Aeroplanes are designed to possess a certain amount of "stability," or natural balance. It would be intolerable for the pilot if every tiny gust of wind, every variation in the density of the air or the nature of its invisible currents, and every movement on the part of himself and his passengers, had to be corrected by a movement of one or other of the controls. Consequently, every machine is given a greater or less power of balancing itself against forces which tend to make it—

1. Roll from side to side (lateral instability).
2. Pitch from end to end (longitudinal instability).
3. Yaw to right and left of its course (directional instability).

The lateral dihedral is a device for conferring or improving lateral stability, and it consists of inclining the main planes upwards from the centre towards their wing tips, as shown in fig. 1 (left), which is a silhouette of a monoplane flying straight towards the reader. Dotted lines dropped from the ends of each plane to a ground line show that the horizontal equivalents (A B and B C) of both planes are equal. Other things being equal, the lift afforded by a wing is proportionate to its H.E. (horizontal equivalent). In fig. 1 (right) the same monoplane is shown tilted over to one side by any imaginary cause. Notice that the H.E. of the lower wing (A B) is now much greater than that of the upper wing (B C). The lower wing therefore exerts correspondingly more lift for the moment, and tends to throw the machine back on an even keel. If the wings were mounted in the same straight line with no dihedral the H.E. of both wings would be equally affected by a tilt, and no righting effect would be produced.

The weakness of the lateral dihedral lies in the fact that it has both to resist the sideway tilt and also to fling the machine back on to a level keel. It can only do this if the dihedral is sufficiently sharp to make a very appreciable difference in the horizontal equivalents of the two wings during a tilt. If this is done the H.E. is permanently reduced, and lift is sacrificed. Consequently, few designers employ less than a 170° dihedral, which is barely perceptible to the naked eye in a plane of fair span, and in flight exerts but a small righting influence.

Longitudinal Dihedral.—This tends to improve longitudinal stability, *i.e.*, it is a corrective of fore and aft pitching. This angle is shown in fig. 2, and exists not between two adjacent planes, but between two imaginary lines, illustrating the relation between the main plane and the tail plane. These lines are the "chords" or (more accurately) "neutral lift lines" produced till they meet. In fig. 2 the tail plane is obviously mounted at a different angle (of incidence) from the main plane. Otherwise, in geometry, their chords could never meet, but would be parallel. Actually, the effect of a longitudinal dihedral is produced in flight even when the main and tail planes are mounted at the same angle of incidence, because the main plane deflects the air downwards, and the tail plane therefore has a different angle *in relation to the air*, though it is fixed at the same angle in relation to the fuselage.

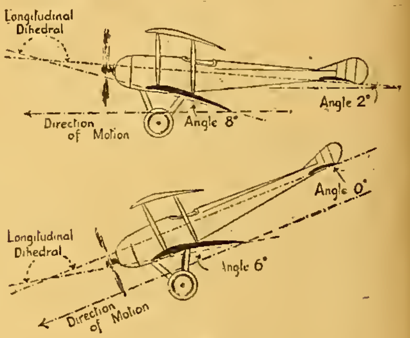

Fig. 2.

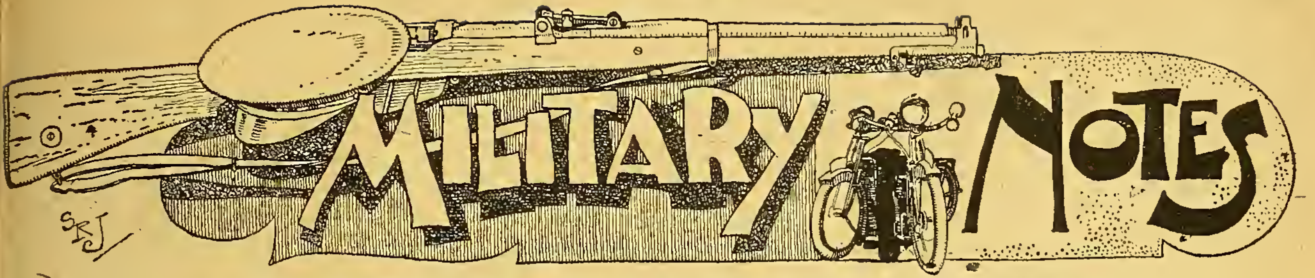
Fig. 2 illustrates how the longitudinal dihedral works. The main plane is given by the designer a normal angle of incidence of 8°, and the tail plane one of 2°. In the upper sketch the machine is flying horizontally, and the planes retain their normal angles. In the lower sketch the nose of the machine has bumped downwards, owing to atmospheric conditions. But it is no longer flying along a line dictated purely by its own thrust. A combination of forces, including the engine, gravity, and the air pressures, generated by its planes, is trying to make it fly downwards. On the other hand, the impetus gained in its level flight prior to the bump is trying to drive it horizontally. Its new direction is a compromise between the old impetus and the changed direction of the thrust due to the bump. It is, to commit a bull, flying at an "unnatural" angle, and this "unnatural" angle has reduced the angles of incidence in the case of both the main and tail planes. Suppose that each of them has lost 2°. The angle of the main plane is now 8°—2°, *i.e.*, it has lost a quarter: the tail plane is now 2°—2° *i.e.*, it has lost all. In other words, the tail plane has lost more of its lift than the main plane, since at these low angles the less the angle the less the lift. Down flops the tail, and the machine reassumes a level fore-and-aft position, though at a lower altitude than when the bump occurred.

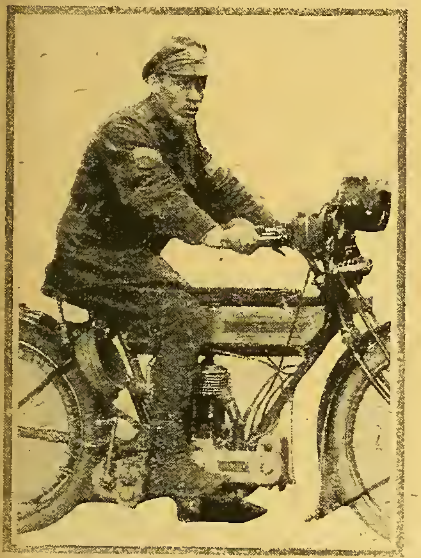
If a bump jerks the nose of the machine up, the converse action takes place.



A Famous Tennis Player. A Fine Record. Post-war Trials.

A FINE RECORD.

CPL. C. T. EVANS, M.M., Motor Cycle Despatch Rider, R.E., has been awarded a Bar to his Military Medal, after a splendid record of service. He enlisted the first week in August, 1914, went to France early in September, 1914, and has been there ever since. He was mentioned in despatches for gallantry in June, 1916, was awarded the M.M. for bravery in the field in September, 1916, and the Bar to his M.M. in May, 1918. He also holds the 1914 Star. When over on leave in November last he was called to Warwick, and was there presented with the M.M. by Brig.-Gen. Grove.



Cpl. C. T. Evans, M.M.

Previous to the war he was employed at the Rover Motor Co. (fitting department), Coventry.

* * *

HOW A. F. WILDING MET HIS DEATH.

AT the time we recorded the death of Capt. A. F. Wilding, R.N.D., the enthusiastic motor cyclist and champion lawn tennis player, who was killed in France three years ago, the way in which he met his death was not known to us. We now read in a contemporary, *The Auto*, that, while carrying despatches along a road which was being heavily shelled, Wilding passed a shelter, and, yielding to the persuasion of comrades who had already taken cover, he entered the refuge. A few seconds later a shell landed on the top of the shelter killing instantly all the inmates. The story is vouched for by Major R. S. Prentice, Overseas representative of the United States National Lawn Tennis Association.

* * *

KILLED WHILST FLYING.

IT is with regret that we learn that Sec.-Lt. Lewis Mogridge has been killed whilst flying.

He was a well-known competition rider prior to the war, having ridden V.S., Mead-Precision, and Rudge machines. He was a member of all the Liverpool Clubs, also of the Westmorland and one or two London Clubs. He was known as a competitor in the London-Edinburgh, Birmingham to Land's End, and other long-distance competitions.

At the outbreak of war he offered his services as a competent motor cyclist to the Inspecting Officer of the Motor Cycle Reserve Committee, West Lancs, Divl. Area, together with the late Lt. Felix Baxter, V.C.

For some little time after they applied there was no vacancy. Eventually they both obtained commissions, both being attached to the 8th Liverpool (Irish). Poor Baxter was killed. Lt. Mogridge served in France, and was invalided home with trench fever. During his convalescence at home he made application for transference to the Royal Air Force. This was granted, and he was accepted and trained, and eventually went Overseas, where he was killed whilst just starting a flight.

FRENCH AIR ACHIEVEMENTS.

FIFTEEN French airmen have brought down between them a total of 289 enemy machines. This number extends back over a considerable time, but Fonck, who is responsible for forty-five, brought down several quite recently.

* * *

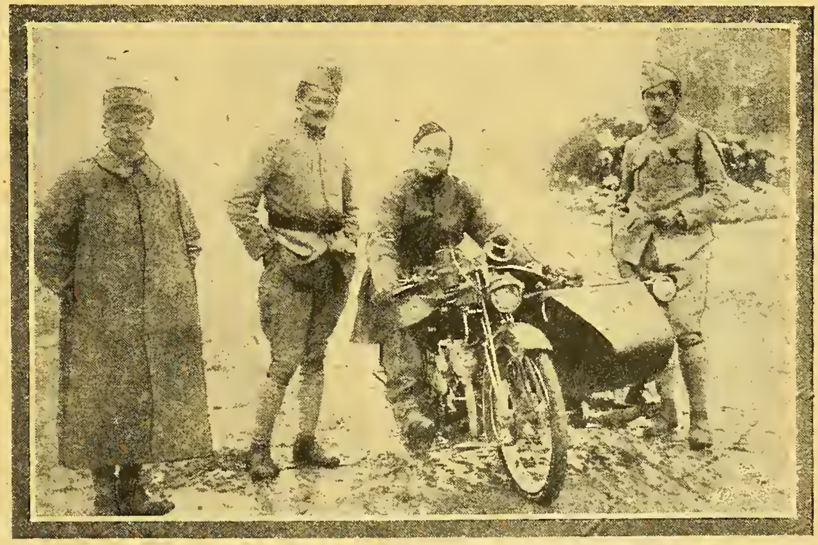
TRIALS AFTER THE WAR.

CPL. C. E. GREEN, R.E., and Cpl. J. Rhodes, R.E., both send chatty letters from France, and, curiously enough, touch upon the same topic—competitions after the war. Green hopes for the old days again, hill-climbs, and long-distance trials. Rhodes, however, says, "If we never have hill-climbs again very little will be lost. They were only of slight value to the trade, and not much use in eliminating the weaknesses of motor cycles." The question is a debatable one.

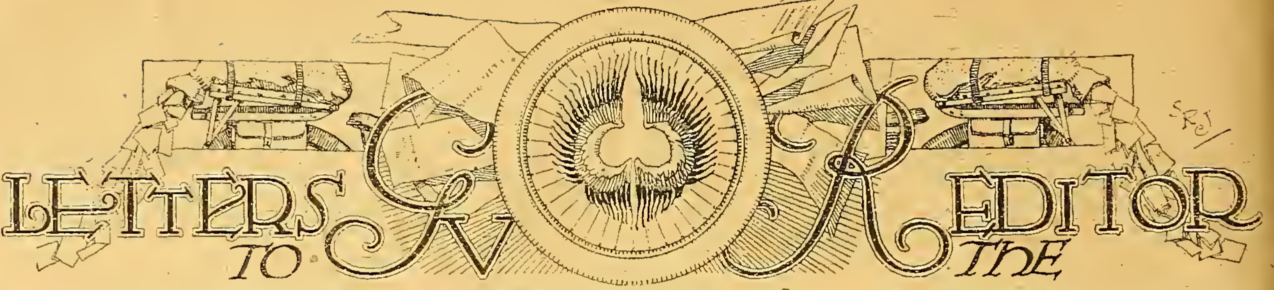
* * *

WITH THE TANKS.

IN a letter written from France, Pte. McDonald says that he has had an extremely rough time during the campaign. He joined the Tank Corps in 1916, and his first experience in "going over" was in June, 1917. He writes also of the later attacks in February, 1918. He drove an M.T. vehicle from the retreat of Antwerp in the first days of October, 1914, and was also in the forward area for two years. He was an enthusiastic motor cyclist.



Air-Mechanic T. P. Dixon, R.F.C., on his P. and M. and sidecar somewhere in the mountainous parts of France.



LETTERS TO THE EDITOR

The Ed tor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—*Re* the letter of "A Few M.T. Fitters" in *The Motor Cycle* of May 2nd, it is pleasing to note the "Few" in their *nom de plume*, as that must exactly describe them. To say that motor cyclist and car drivers (car drivers are technical, by the way) are under no circumstances allowed to do any repairs or adjustments is absolutely misleading, and not a truthful statement. My chum and I have been out here two years, and have done all repairs and adjustments, as a fitter is not included on our strength.

How do the "Few" account for road repairs which, in the balloons, are many, and I might add that our greatest terror is the overhauled remount, which we always have to put in order; but then perhaps one of the "Few" has had the matter in hand.

Trusting you will find space in your always welcome paper,

B.E.F. BALLOONS.

POLISH ON CARBON BRUSHES.

Sir,—In your issue of May 23rd, in reply to query *re* overhauling a magneto, you state, "If the ends of the brushes are polished, roughen them over lightly with glass-paper."

May I bring to your notice a paper on "The High-tension Magneto," by Mr. A. P. Young, A.M.I.E.E., A.I.A.E., read before the Aeronautical Society, April, 1917, in which the author states, Part 3, Section 4. "I am informed in certain quarters a carbon brush having a highly-polished contact face is looked upon with suspicion, and in consequence it is the practice to remove the polished surface by the careful application of a file.

"This is a most pernicious habit, and cannot be condemned too strongly."

I may say that since discarding the file habit I have obtained far better results than heretofore, and am convinced that it is a point which might with advantage be brought before your readers. T. CARPENTER.

HIGHER GEARS FOR SOLO RIDING.

Sir,—In reply to "Argon," I should like to point out that a gear exists which is substantially in accordance with the requirements he sets forth.

This gear is the property of two friends of mine, who, owing to being engaged on work of national service, have been compelled to let its exploitation stand over until the end of the war. The contrivance, though of a friction type, is, as far as is mechanically possible, *frictionless*.

It is positive and so extremely simple that it may well be regarded as absolutely fool-proof. It may be used for chain, belt, or shaft drive on any class of motor vehicle from solo mount to a motor lorry.

One somewhat extraordinary feature of this variable gear is that the necessity of lubrication is practically done away with, as is also the necessity for a gear box or any other covering.

So much confidence have I in the gear that my friends are bound by promise to me that they will provide me with a specimen for use on a four-cylinder sidecar mount I am hoping to run as soon as Fritz is a back number.

R. G. TUCKETT.

AIR COOLING.

Sir,—After reading the article on "Air Cooling" by such a giant of motor cycling as "Road Rider," one wonders timidly how such a contraption as a motor cycle—bar, of course, the A.B.C.—ever proceeded ten consecutive miles at 30 m.p.h. without dissolving into horrid splashes of molten metal. It must be lovely to be able to draw beautiful diagrams with wiggly lines all around them, but somehow they do not seem to prove much. Take diagram 5, for instance—the second sketch. Having "noted the vacuum" I marvel that my machine ever fires at all. It is fitted with a hot air elbow and pipe, and draws the whole of its air supply through an inch pipe pressed against the fins in the *centre of the "vacuum,"* and it fires quite happily at 50 m.p.h. Where *does* the air come from? Again, the streamline fins look beautiful from above, but would eight or ten fins, each perhaps one-twelfth inch thick, induce the circumambient air to take a streamline form? Also would not the crude outlines of the carburetter—conveniently omitted in the diagrams—rather spoil the symmetry of the streamline shape? Does "Road Rider" know that there is one firm—whose cylinders are neither streamlined nor steel—who claim that they have never heard of one of their valves breaking in ordinary use. Now, are their machines generally considered slow? Mine is one of them.

J. M. PHILPOTT.

FIXING THE GUDGEON PIN.

Sir,—We have been interested in the various methods of gudgeon pin fastenings which have recently appeared, particularly in the issue of May 16th. We have experimented with many methods, including the type recommended by "Chinook," *i.e.*, piston ring method, and certainly cannot recommend this as a thoroughly satisfactory job. It neither prevents the pin from turning—unless the ends are slotted, forming part of the piston ring groove—nor does it prevent movement of the ring endwise. We have used narrow and broad rings, also steel wire spring rings, and have also passed a spring wire ring round the piston and through a hole in either end of the gudgeon pin, this last method being the most successful of that style of fastening; but the method which has for the past few years proved itself far and away ahead of any other we have tried—both from the standpoint of reliability and of easy removal and replacement—is that shown in the accompanying sketch. The pin is parallel and is a push fit into the piston bosses, one end being fitted with a key, which engages a keyway cut in the side of the piston boss. Passing through the other end of the gudgeon pin is a hole at right angles to the key, this, when the gudgeon pin is *in situ*, registering with a slot in the waist of the piston passing across gudgeon pin hole. An ordinary split cotter is then threaded through the end of the gudgeon pin, and lies snugly in the slot in the side of the piston. This, with the key, prevents any possibility of endwise movement, and the key prevents any turning of the pin. It will be seen how easily the whole business is removed and replaced, and there is nothing whatever liable to come loose.

A BAFFLING EXPERIENCE.

Sir,—May I thank the readers who have been kind enough to endeavour to diagnose the trouble related by me in your issue of April 18th.

Some of your correspondents have, I fear, not had the facts as published fully in mind when replying to my letter. In reply to "A.G.C.," who writes in the issue of April 25th, I beg to say that the control wires and high-tension wire were in perfect condition and could not have been causing a short circuit.

The Lodge Co.'s suggestion has already been most admirably answered by Mr. Peasnell. It certainly would be too much of a coincidence for the rocker arm to stick when the plug was *in situ* and to work when the plug was taken out and laid on the cylinder. I think this must be dismissed as most improbable. In reply to Mr. Peasnell's query, I had no straps or knee grips round the tank, and I was using one of Lodge's umbrella terminals.

Mr. Moon's suggestion in the issue of May 2nd struck me at first as being a possible solution of the trouble, as the weather was damp, and I had been out for some hours. Under these conditions the fibre block (not bush) on the Splitdorf magneto rocker arm might have swollen. This would have caused the block to engage with the cam of the timing lever sooner and caused an early spark. It would also cause a bigger gap at the points than normal, which would probably give a weaker spark. I am anything but an expert, and am almost afraid to pen my thoughts in case I give the knowing ones much cause for mirth by some unguarded remark, but it seems to me that whether the spark was early or whether it was weak it should be accompanied (or followed, shall I say) by a shock at the plug when held, and this is what I did not get, *vide* my letter in the issue of April 18th.

It should be borne in mind that the rocker arm bush on the Splitdorf magneto is not fibre but metal-to-metal, lubricated with typewriter or clock oil, and I have never found it stiff or inclined to stick up on any occasion upon which I have tested it.

Under the circumstances, after reading the letters of those who have so kindly related their own experiences, and after an amount of mature thought on my own part, I have still to consider the instance as a baffling experience."

F. W. CHAPMAN.

AN APPRECIATION.

Sir,—One unfortunately hears so frequently of the unbusinesslike methods of the British manufacturer, and also reads so many letters comparing British machines unfavourably with American types, that I make no apology for writing to tell you of my own absolute satisfaction with a thoroughly British production used under very trying conditions, and loaded far in excess of what one might reasonably expect the machine to stand up to. I may say that, having been a rider since the days of De Dion tricycles and front-drive Werners, I am hardly a novice, and I must say I have given my present mount every care and attention.

My machine is an Allon, which I purchased slightly second-hand in 1915, it having done only a few hundred miles. I have now completed a little over 16,000 on it, riding every day and in all weathers, with a light sidecar, and for the greater part of the time with a passenger up. On three occasions have I towed home heavy C.B. combinations, and once a light car of well-known make whose differential had broken.

This little lightweight will take 20-24 stone total passenger load on any main road, and face practically any hill without overheating. I once with a very light passenger climbed Cheddar Gorge, which I hardly expected to do. Petrol consumption is just over 80 m.p.g. with two up on an ordinary give and take road, and I find the two-stroking perfect at practically all speeds.

When I first took the engine down after purchase there was a very small crack in the piston, which did not seem enough to be serious. However, after 16,000 miles this developed, so I wrote and told the makers and asked for a quotation for a new piston, explaining to them that I had no cause for complaint, the machine being second-hand when I bought it, and having more than satisfied me throughout. *By return of post* came a reply, asking me to send the engine along for overhaul. I wrote saying I could not spare it, and immediately the makers sent me free of charge a new piston, with rings, gudgeon pin, etc., and also a few minor spares that I needed. Could any firm be more courteous or prompt in their treatment of one who was not even in the first place a direct customer, and of whom they had not previously heard? I think not, and after two years' perfect satisfaction with the machine it gives me added pleasure to find the makers are as reliable as the machine they turn out.

L. F. BISHOP (Sec.-Lt. R.F.C.)

NUTS AND THREADS.

Sir,—May I ask the favour of a few lines in your valuable paper to put forward a few observations on details of British and American motor cycles? I have been wrestling for an hour and a half trying to induce a nut to screw on to a footrest bolt of a popular lightweight machine. The footrest, I may add, I was foolish enough to tap on with a hammer previously to dismantling, and damaged the thread in consequence. I have always noticed that with British machines —I have owned eight or nine—the larger bolts were either too tight or too loose a fit, and the threads were exceedingly easy to destroy. All the British machines were of the best. Now to come to the American machines. I have had four different makes, and the threads of the bolts were very hard, and the nuts always screwed up a certain distance with the fingers. Surely British manufacturers can come up to the standard of American in their bolts and threads. This, of course, is a small matter to most; but as I endeavour to do all my own repairs, and time is of consequence, I put off the fatal day of repairs for a long while, when barked knuckles and bad temper can become normal again!

Another point. I was reading your paper, and saw an 8 h.p. combination listed at £125, *lamps, etc., extra.* This sort of thing is surely not a great inducement to people, who can get an Indian—in my opinion, the finest machine made—and sidecar for a few pounds over £100, with electric lamp, electric horn, and a hood and screen thrown in. This makes a man with £100 to invest in a tip-top sidecar machine plump for the American every time.

Needless to say, I have no interest in the Indian firm, except as a heartily satisfied user.

D. KINLOCH KIRK (Capt.)

American troops in France. Negro driver and colonel passenger on a B.S.A. on the Western Front.

COMFORT IN RIDING.

Sir,—With reference to fig. 2 on page 406 of your issue of 25th April, 1918, I wish to point out that the machine illustrated was not a converted tricar, but was one of a type which was built in Newcastle-on-Tyne in 1907, the chief features of which were wheel steering, bucket seat, clutch, two-speed gear box, and hand starting. S. HUNTER.

[The inscription stated that it was *possibly* a conversion. —ED.]

A SUGGESTION—AND OTHER MATTERS.

Sir,—On reading your valuable paper of May 16th, I note you say that there are many Triumph two-stroke motor cycles in use by His Majesty's Army Overseas, and it has occurred to me that it would be rather a good thing if some of the less important and dangerous jobs on the fighting fronts were done by youths from fifteen to sixteen mounted on these handy little machines. There would be a great saving in petrol and man power, to say nothing of machines, etc. This should prove economical, and would train the boys under war conditions for the Air Service on reaching the age of eighteen.

I am very interested in any letters from your readers in regard to the four-cylinder. I once rode a Henderson for a few miles, and was charmed by the even running.

In regard to an ideal Overseas mount, I should think that the twin two-stroke made by Messrs. Butterfield, makers of the Levis, of, say, 5-6 h.p., three-speed countershaft gear, large mudguards (fully 3in. clearance), enclosed chain drive, with tank to hold not less than two gallons (made after the American style), 28in. wheels, and 3in. tyres, should make an excellent machine.

I think that all your readers should be thankful, and also proud, of their choice when they chose your paper, and I thank you, sir, for keeping the paper still as interesting as ever, and hope that you are having the tremendous success that you rightly deserve. OLD READER.

AN OCCASIONAL "KONK."

Sir,—I wonder if you or any of your readers could tell me the cause of the following mishap, which occurred to a second-hand 1912 Scott which I have lately purchased? The engine was running very badly (misfiring, etc.) when I got it, so I at once set to work and made all the joints gas-tight, cleaned up the gauzes in the transfer port covers (only single gauzes were fitted), attended to the magneto points, plugs, etc., but, as very little improvement was apparent, I decided to try another carburetter, and so fitted an adjustable jet B. and B., which I am still using. This improved the running a little, but I could get no speed or power or even running, so decided to take the whole engine down. (In this connection, may I ask if there is any "golden rule" or easy way of fitting or removing the short water connection to radiator?) On completing this operation I found that one of the cranks had sheared its key and twisted round about 90° in relation to the other. This I had put right at one of our best garages, and then I reassembled the engine very carefully, paying particular attention to making all joints absolutely gastight.

The engine started up at the second or third kick and ran smoothly and well, and I thought my troubles were at an end. Not so, however, for I was troubled by an intermittent and most violent "konk," which occurred at any speed and with any setting of the levers or timing of the ignition. Sometimes it would occur every one hundred yards or so and at others I might ride perhaps four or five miles without it happening, but then it would suddenly occur again—just a single, violent, ringing "konk" from the poor engine's vitals. The strange part was that the running seemed unaffected and continued even. I tried timing the magneto slowly, and I also tried lowering the level of the petrol to about ⅛in. below the top of the jet. I could not obtain the Reliance plugs recommended for Scotts, so fitted two new Hobson Pognons. Returning home one day, I had just made up my mind to try fitting double gauzes in the transfer ports in case my trouble should be due to explosions in the crank case, but all at once the engine jammed with one of the usual "konks," and investigation disclosed the sad fact that the cranks had again twisted, and were in almost the same position as before—90°. I have again had the damage repaired at considerable expense, and have just got the machine running again and have fitted the extra gauzes, but a trial run revealed that the same old trouble was still in existence, and now I am at a loss to know how to account for it. As I am too far away to await *The Motor Cycle's* valuable advice, I shall continue to experiment on my own in the meanwhile, but I should nevertheless be very grateful for any tips. I might mention that I have owned and ridden machines of most makes on the market, from 2 h.p. singles to big four-cylinder machines, and so have considerable experience, though the Scott is my first two-stroke, and so is a bit of a puzzle yet!

Graaf Reynet, South Africa. ALLAN R. BIGGS.

AVERAGE SPEED.

Sir,—May I butt-in with a few words on the paces of the Sunbeam?

A reader states that 52 m.p.h. is the fastest speed he has attained on a standard 3½ h.p. Sunbeam. I have a solo 3½ h.p. T.T. 1916 Sunbeam, which, standard save for a re-timed spark, will touch 58 m.p.h. by Watford speedometer—top gear 5¼ to 1 (Sunbeam "sidecar" gear).

Why do the super-experts all dismiss the readings of speedometers? Perhaps the manufacturers of the (say) Stewart, Watford, Cowey, and Jones will hand in a few winged words on the subject. I have tested a Watford against a Jones—result, 47 m.p.h. in each case!

It appears that both the A.B.C. and the Norton are the fastest machines on earth of their power. Perhaps Captains Hodgson and Lindsay will arrange a dust-up, and "E.K., R.F.C.," may make an "eternal triangle" of it! All the arguments on earth will do no good; but a trial of the three machines may have some effect. A cup might even be offered to the winner.

I am very interested in this discussion. After many troubles and experience of many different makes, I have at last what I consider the finest all-round, no-trouble machine on earth—in a word, perfection; and I would like to hear of "E.K." proving his claim. A.H.

WHAT WE SHALL GET.

Sir,—"Ixion" has often referred to the high-efficiency engine of small cubic capacity and low weight. He whets one's appetite with "very wee machines streaking up the mountain road," presumably low geared, and depending for their speed on a great number of r.p.m. I have owned many very wee machines, the best of their class, which included two and four-stroke singles and twins, and have pampered and humoured them to the best of my ability, having fed them reasonably with the oil best suited to their individual needs. Some of these babies I have scrapped after the first few hundred miles; others I have run close on 5,000 miles before parting with them. Some of these "new brooms" were capable of streaking up North End Road, Hampstead, on top gear at the appalling speed of 18 m.p.h. "all out," but it was not long before subsequent rides up the same hill had to be negotiated on second gear, or a slipping clutch, and their embarrassment in the shape of overheating, etc., was distressing to witness. There is no doubt that during the period the small "'bus" remains in good tune it is quite a useful mount for short distances, but, apart from the usual drawbacks of small wheels and tyres and short life of the engine, the great majority of small engines possess one serious defect. I refer to the intolerable nuisance of having to decarbonise the cylinders every few hundred miles. However careful one may be in regulating the lubrication, jet, etc., the fact remains that the small engine loses tune (power) more quickly than does that of greater cubic capacity, which I believe is due chiefly to the difference in gear and r.p.m. An 8 h.p. twin I owned in 1913 ran for 3,600 miles before a slight falling off in power occurred. Opening the throttle an extra ⅛in. then gave me all the necessary reserve power to carry on for a further thousand miles. I then decarbonised the cylinders, not because of "knock" occurring, but for the reason that I felt it was cruelty to dumb animals to continue.

A small engine (one of "Ixion's" post-war "babies") will require to be designed exceptionally well and run very cool indeed to give the same satisfactory results.

My present baby twin, with but a few miles to its credit, has more than once caused me grave anxiety when laboriously dragging me up a steep hill on second gear. The engine revs. are simply terrific, and I fully expect one day to see the thing turn inside out with "revvingitis."

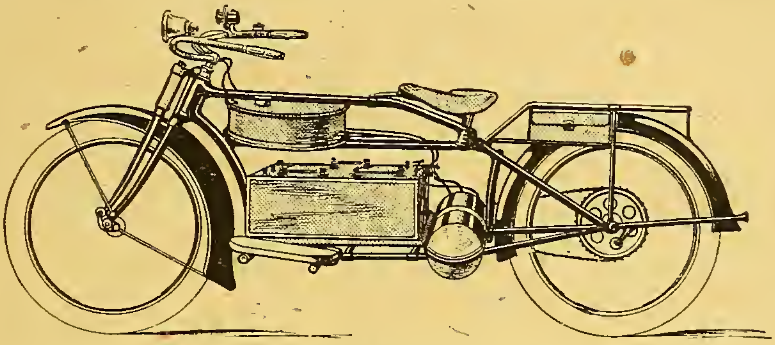
Golder's Green. VIC.

An Electric Motor Cycle.

DETAILS OF AN INTERESTING NORWEGIAN EXPERIMENT.

FROM a Norwegian source comes a description of a motor cycle driven by electricity, which has been invented by Johannes Bjorge, of Christiania, Norway.

We are in some doubt as to whether it is a completely designed electric cycle or an ordinary American motor cycle converted for the purpose. It appears to be the usual type of frame for a four-cylinder engine with accumulators in place of the engine unit, and an electric motor mounted in place of the usual countershaft gear box driving the back wheel direct by a chain. The elliptical box in place of the tank contains the controllers and regulating devices.



A motor cycle designed to be driven by electricity, the invention of Johannes Bjorge, of Christiania, Norway.

A trial demonstration was recently given before a number of Norwegian motor cycle representatives, and their reports are favourable.

The weight is about the same as that of an ordinary motor cycle. There is said to be sufficient power in the storage battery fitted for about forty-five miles riding, but the inventor is at work on a specially constructed battery, which he hopes will give a range of seventy-five miles without recharging. The maximum speed is about forty miles per hour on the level. The running cost of the machine is said to be about four miles for one penny. A further development upon which the inventor is working is a permanent addition to the machine to facilitate recharging wherever electric current is available. We are not convinced that there is anything particularly new or novel in this attempt to produce an electrically driven machine, but it certainly affords possibilities in the way of converting a motor cycle to avoid the use of petrol or coal gas. Whether a storage battery of any efficiency could be temporarily accommodated in place of an ordinary engine unit, single or twin, and whether a lightweight motor of sufficient power could be driven therefrom, are points in doubt. We imagine that many English riders and makers have considered the *pros* and *cons* of this method of driving a motor cycle, and possibly have arrived at the decision that the probable result is not worth the expense. The electric motor cycle is still some way ahead in the future.

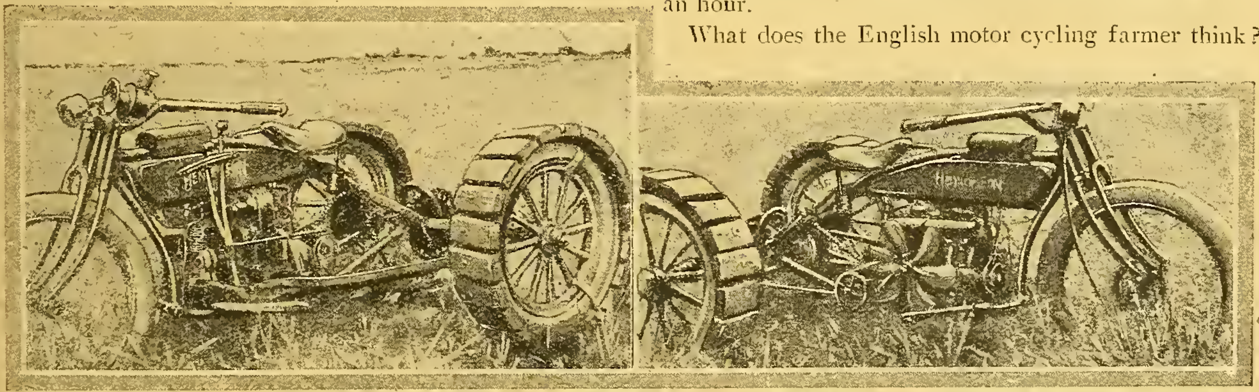
There is no reason why it should not come, but steam may turn out to be a serious opponent.

A Motor Cycle Farm Tractor.

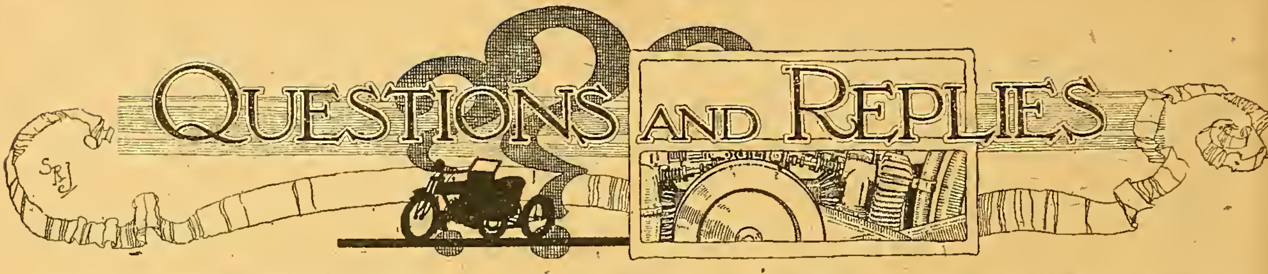
AN American motor cyclist is using his 1917 Henderson for the cultivation of pea nuts. The rear end of an old electric auto is arranged with detachable grips on the tyres, and an ingenious system of gearing gives him a low gear ratio of 20 to 1, with a working speed of two and a half miles per hour. There is no difficulty in pulling a 12in. plough, but it is best adapted to pulling a cultivator or a harrow. By hooking the beam of the plough close to the differential, and setting the shear so that it has a tendency to drag down on the tractor wheels, he has plenty of traction.

The arrangement is readily detachable, and the machine can be converted into a solo mount in half an hour.

What does the English motor cycling farmer think?



A motor cycle tractor is certainly an innovation, and although about the last use to which one would think a motor cycle should be put it has proved a success. Note the cooling fan, which was effective in keeping cool the Henderson four-cylinder engine.



QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Books.

Have you any books published on the timing of engines and magnetos? If so, kindly let me know.—P.

"Motor Cycles and How to Manage Them" deals with all matters connected with motor cycle engines, and "Electricity and the Motor Car" is a complete and exhaustive book on magnetos, as well as other forms of ignition. The price of the former is 1s. 10d., and that of the latter 2s. 10d., both post free from the publishers of *The Motor Cycle.*

Driving from the Sidecar Seat.

(1.) What, in your opinion, would be the best and easiest motor cycle to convert so that it could be driven from the sidecar? (2.) Would a Royal Enfield be suitable? (3.) Do you think a machine fitted up in this manner would be satisfactory and keep the road as well as if it were driven from the saddle?—A.S.

(1 and 2.) There are so many aspects to be considered in the conversion you suggest that we cannot say if one machine would be more adaptable from every point of view than another. However, the 6 h.p. Royal Enfield would be as good as any. (3.) The question of service to be obtained from such a machine is rather a controversial one, and has been several times treated in *The Motor Cycle.* We should think it would hold the road better with all the weight in the sidecar than if it were driven from the saddle.

Illumination from Magneto Current.

(1.) Is it possible to use a magneto on a $2\frac{3}{4}$ h.p. Douglas motor cycle for lighting the front and rear lamps? (2.) If so, how is the wiring carried out, and what connections are made to the magneto? (3.) What voltage lamps are suitable? (4.) Should they be carbon or metal filament lamps? (5.) Does the system harm the magneto? (6.) Is the system satisfactory? (7.) Can you give me a recipe for a petrol proof varnish?—P.F.

(1.) Yes. (2.) You should refer this question to the makers of the device, Messrs. F.R.S. Lamps, Ltd., Beam Works, Pershore Street, Birmingham, who can supply you with a complete outfit. (3.) Four volts and of low amperage. (4.) Metal filament is preferable. (5.) No; it does no harm to the magneto. (6.) Yes; but the light is only moderate (7.) There are several proprietary petrol-proof varnishes on the market. We think that shellac dissolved in acetone would suit your purpose

Petrol Starting Jet.

I should be obliged if you would inform me if a jet supplying petrol tapped into the induction pipe of a $3\frac{1}{2}$ h.p. Rudge, fitted with Senspray carburetter, would enable one to start the engine if the levers were kept in a position to avoid drawing paraffin from the carburetter jet. It would simplify the use of paraffin very much, as it is very messy draining the float chamber and refilling with petrol. The engine runs all right on paraffin when once started. —J.J.A.

Yes; if the pipe supplying the petrol to the induction pipe were fitted so as to project into this pipe about $\frac{3}{16}$in., and suitable provision for air supply and jet were made.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD

Retiming an Old Model.

I have dismantled and reassembled the engine of a 1911 $3\frac{1}{2}$ h.p. Rex to replace a damaged timing pinion, and now I cannot obtain correct firing owing to the timing being incorrect. Would you be good enough to state what is the proper timing for both ignition and valves?—R.M.L.

The following is approximately the correct setting for a $3\frac{1}{2}$ h.p. engine. It is, however, possible that experimenting might provide some slight improvement. The exhaust valve should be down on its seat at the termination of the exhaust stroke. If you set it that way the valve will commence to open at the right time. The inlet valve should begin to open when the piston is at the top dead centre of the exhaust and inlet strokes, and should be closed when the piston has travelled $\frac{3}{8}$in. upwards on the compression stroke. Magneto timing: Place the piston exactly on top dead centre of the compression and firing strokes and connect up the magneto drive with the points of the contact maker just about to separate, and the ignition lever fully retarded.

Using Paraffin.

I have a 6 h.p. Rex-Jap twin motor cycle. Is it possible to make this machine run at all efficiently on paraffin or three parts paraffin to one part petrol? If so, will you please tell me how to do it? Is there an efficient vaporiser for such a machine?—G.A.C.

Yes, it would be quite possible to make the machine in question run on paraffin. It is necessary, first of all, to have a hot air intake to the carburetter, and perhaps to wind the fuel pipe, say, twice round the head of one of the cylinders, so as to heat the fuel before it reaches the engine. After starting on petrol the machine ought then to run satisfactorily; or you might fit a vaporiser, of which there are several on the market.

Garage Morality.

On August 2nd, 1917, a provincial garage accepted a repair to the magneto on a Scott motor cycle. This repair was completed in about two months. Since then, through negligence, the crank case has been punctured and piston broken. I have made visits, also repeated applications, for the machine to be returned in running condition; but the garage proprietor says he is too busy on war work to reassemble it, but will let me have it in parts. I have a permit allowing me to use petrol for business purposes. The machine, which has been in this man's care the whole of the time, has depreciated £20 in appearance, through being exposed to the weather. Will you please advise me how to lay a claim, and what chances I have of success?—Perplexed.

As far as we can say, without actually seeing your machine and without hearing the garage proprietor's version of the case, we should certainly imagine you have good cause for complaint and should have no difficulty in securing adequate satisfaction through the courts. Have you suggested to the garage proprietor that you will be compelled to take legal proceedings if he does not adopt a more reasonable attitude? If you have not done so, you might suggest this to him; and if it has no effect, put the matter in the hands of a local solicitor. If you take the matter into court, you will have to prove to the satisfaction of the judge that the damage to the machine is due to the negligence of the repairer, and that he has not taken reasonable precautions with your machine, and this, we should imagine from your letter, you will have no difficulty in doing.

Strength of Magnets.

I have a magneto, the magnets of which, I think, are run down. Will you please tell me the way to test for weak magnets, also the name and address of a good firm who will remagnetise these?—G.A.E.

There is only one way by which you can test the strength of magnets, and that is by holding a steel article against them, with armature in a certain position, and noting their relative pull in comparison with magnets which are known to be well magnetised. Magneto machines seldom lose magnetism unless they have had the armature removed from the tunnel without a "keeper" being placed across the magnets. The only indication of weakness is that the magneto will start the engine only with difficulty, and will give a very weak spark at the plug when the engine is rotated. If the magnets want remagnetising, send the whole magneto to its makers, whoever they may be. The trouble is far more likely to be due to a faulty contact maker.

Motor Cycle for Business.

I am about to purchase a motor cycle to be used for business purposes, *i.e.*, I live about six miles out of a town where there is no convenient rail, etc. (1.) I presume there is nothing to prevent my accepting a friend's supply of petrol? He is called to the Colours, and has given me his supply—the accumulation of several months. Am I likely to be pulled up by an official of any sort to produce a petrol licence? (2.) What taxes am I liable for, and in the event of my purchasing a second-hand mount shall I be liable for the Inland Revenue tax, even though this tax is not due till January in each year, and the present owner of the machine has paid the tax for this year? (3.) What, in your estimation, would be a fair price to pay for a combination (cycle and sidecar), second-hand? (4.) I have been told on no account to purchase a machine of earlier type than 1914. Is this correct, do you think? (5.) Have you ever had any complaints as to unfair treatment of purchasers by advertisers in your journal?—A.M.

1.) Your friend acted illegally in giving you petrol, and you also in accepting it; but this will not affect the legality of your using the spirit. The Motor Spirit Restriction Order entitles licence holders and others who can obtain motor spirit to use it for business and also for other purposes when no other reasonable means of transit are in existence. (2.) The Inland Revenue licence is 20s., driving licence 5s., and registration 5s. in the case of a new machine or 1s. for the transfer of registration if a second-hand one. You are liable for the Inland Revenue licence within twenty-one days of using the machine on a public road. (3.) So much depends on the make and age of the machine that we cannot answer this query, but a good second-hand machine should be obtained for £50. (4.) If the machine has had little wear, a 1912 is not too old. (5.) Yes. The best safeguard is the deposit system.

Joining a Mechanical Unit.

Can you tell me if I can get into the R.E. or R.A.F. as a despatch rider, or the M.T., A.S.C.? I have passed two D.R.'s tests on previous occasions, but was rejected by the doctor in each case. Later I was graded C1, but have held Tribunal exemptions, as I have been managing my mother's business, owing to the depleted staff. Now I am Grade 1, and shall not be called up until after July 1st. My age is twenty-three.—C.H.W.

The only thing for you to do is to apply to your local R.O., or, for that matter, to any R.O. who has vacancies for despatch riders if your own R.O. has no such vacancies. As you have passed the D.R. tests, you ought to have no difficulty in securing the position you require, if you can find a vacancy.

The Paper Restriction Order

"RETURNS" PROHIBITED FROM JUNE 24TH.

Now necessary for readers to give a definite order for "The Motor Cycle" either to a newsagent or the publishers.

An official Order has been issued by the Board of Trade which prohibits the system of supplying newspapers on "Sale or Return."

This comes into force on JUNE 24th, and after that date only those readers who have given standing orders can be sure of obtaining their copies of *The Motor Cycle.*

In the past it has been the custom to allow newsagents to return unsold copies and this enabled them to hold supplies for the convenience of travellers and other occasional purchasers.

Under the new Order this custom must cease, and newsagents obviously cannot be expected to risk having unsold copies left on their hands. In future they will take enough copies to supply definite orders only.

Readers who have not already done so should give their orders for "The Motor Cycle" at once and thus avoid disappointment.

Timing a Two-stroke.

(1.) Can you tell me if the following timing is correct for a 2¼ h.p. New Hudson two-stroke? I am told to set the piston ¾in. from the top on compression. Is not ¾in. a great deal, and would this be with contact breaker retarded or advanced? What is meant by "on compression," as I thought, in a two-stroke, the piston was "on compression" at the top of every stroke? (2.) Can you tell me what would be a suitable size of accumulator for use on a 2¼ h.p. two-stroke, also the size of bulb to use with it, and how many hours light it would give on a charge?—T.S.McB.

(1.) We should say that for contacts to be about to separate with piston in the position indicated, the contact breaker case would be fully advanced. "On compression" evidently indicates that the piston should be rising on the compression stroke, and not falling on the firing stroke. (2.) A forty ampère-hour Fuller "Block" accumulator should give twenty hours' continuous light for two small bulbs taking slightly less than one ampère each. Four-volt bulbs must be used with a four-volt battery.

READER'S REPLY.

Carburetter Flooding.

Re your answer to "R.F.A." in *The Motor Cycle* of May 9th, regarding the waste of petrol at the main air intake of the Indian carburetter, the fault is in the sluggish action of the needle. Your correspondent will find that slightly enlarging the hole in the carburetter cover will give more looseness and swing at the top of the needle, and he will get a livelier action and a quicker cut off of the petrol. I have ridden Indians since 1913 and had the same experience, no doubt caused by the difficulty in getting the needle into its exact position when reassembling, the needle being bent when screwing down the induction pipe. Also I would advise the permanent removal of the cap over the end of the needle if this is still in position. The inlet valves need no particular adjustment, but the springs must always be kept new and strong. Let him try this, and he will be surprised at the vim of his engine. With congratulations on the success with which you sustain the interest of *our* paper—E. R. MITCHELL.

EXPERIENCES WANTED.

"G.R." (South Wales).—Radco two-stroke. Speed, hill-climbing, and petrol consumption.

"F.B." (Kent).—Searle unburstable inner tube. Resiliency, wear, and puncture-proof qualities.

RECOMMENDED ROUTES.

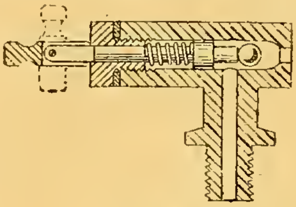
COVENTRY TO BRADFORD-ON-AVON.—G.S.
Coventry, Warwick, Stratford-on-Avon, Evesham, Teddington Cross Hands, Cheltenham, Painswick, Stroud, Nailsworth, Bath, Bradford-on-Avon.

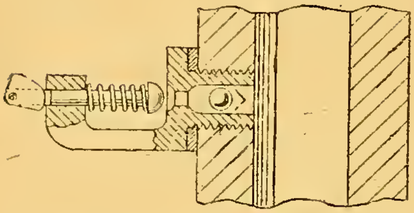
LOUGHBOROUGH TO SKEGNESS.—E.W.
Loughborough, Melton Mowbray, Grantham, Sleaford, Tattershall, Spilsby, Burgh, Skegness.

PATENTS by Eric W. Walford

Auxiliary Air Valve for Two-strokes.

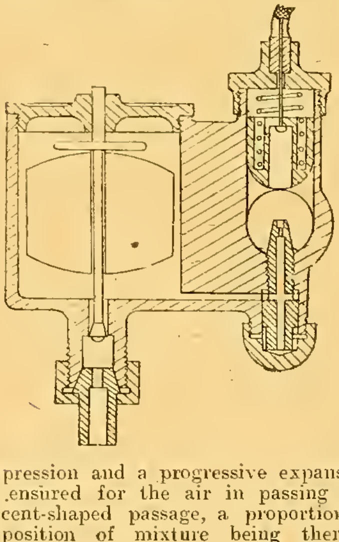
This invention relates to a non-return valve intended to be adapted to admit air to the transfer passage of a two-stroke engine. The air passes into the cylinder in advance of the mixture. Means are also provided whereby the driver is enabled to open or close the valve by external means. The device consists of a ball valve which, when pressed against the smaller orifice by the operating rod, is closed. Alternate applications of the invention are illustrated.—Henry Calvert, Dalton-in-Furness, No. 111,918, December 20th, 1917.





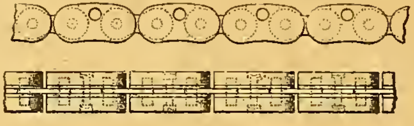
A Carburetter.

This invention consists of a carburetter having the lower part of the sliding member shaped hemispherically, while the sprayer jet is in the form of a truncated cone, whereby a progressive compression and a progressive expansion are ensured for the air in passing the crescent-shaped passage, a proportionate composition of mixture being thereby produced.—Victor Pons, Lyons, France, No. 100,276.



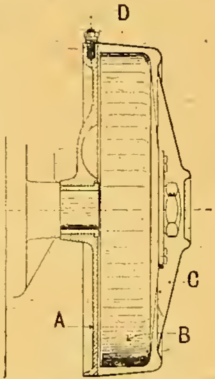
A Link Belt.

A V belt of the link type, in which friction producing links are connected by metallic links. Each frictional link is made with two non-stretchable, non-metallic elements situated on the opposite sides of the ends of the adjacent metallic link, and have apertures to receive the pivot pins of the metallic link.—R. P. Champney, Worcester, No. 111,824.



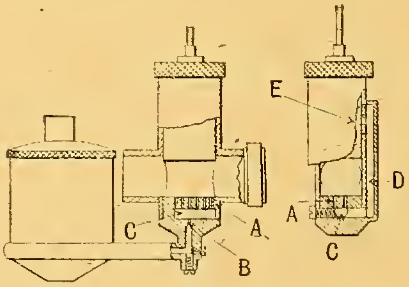
Flywheel Magnetos.

The flywheel magneto is a known device, and comprises a fixed back plate, which carries the contact breaker mechanism, the condenser, the coil, etc., and a front flywheel member, which is mounted on the shaft and carries the permanent magnet. This invention is characterised by the back plate being extended beyond the flywheel member and having a light casing secured to it, which entirely encloses the flywheel member and all the parts embraced between it and the back plate. A is the back plate, B the flywheel member, and C is a dished stamping secured to the back plate by studs and nuts D.—The Villiers Co., Wolverhampton, and G. Funck, Coventry, No. 111,391.



New Carburetter Design.

In this carburetter design it is intended that the liquid fuel be enabled to accumulate when the engine is stationary in a well C, which is in communication with a straight through chamber. In this chamber a sliding piston throttle is incorporated. In the well is located a perforated member A, which acts as an atomiser above the jet B. The well C is in communication with the atmosphere by a conduit D, which is made to communicate with the throttle barrel by a series of perforations E, so that when the throttle is raised the supply of air to the conduit is reduced.—Edwin Hutchinson, Sutton-in-Ashfield, No. 109,505, September 20th, 1917.



SPARKLETS

American Excelsior Spares.

We understand that it is possible to obtain spare parts for the American Excelsior motor cycle from Wm. J. de Greeuw, 27, Maddox Street, Regent Street, London, W.1.

Change of Address.

With reference to the ingenious back springing device and detachable wheel, the invention of Mr. David Levy, which we described and illustrated in *The Motor Cycle* of February 21st, we have to announce that Mr. Levy's address is now at 2, Christchurch Road, Streatham Hill, London, S.W.2, instead of that mentioned in the article.

North British Rubber Co.

The great extension of the business of the North British Rubber Co., Ltd., in the Midlands has rendered it necessary for them to remove from Barwick Street, Birmingham, to more commodious premises, and they are now installed at Clincher House, 158, Gt. Charles Street, to which address all communications for Birmingham and district should be sent.

Catalogue Received.

Douglas Motors, 1918. A tastefully got up catalogue illustrated by pictures of historical interest in the neighbourhood of Bristol, the home of the Douglas. Also profusely illustrated with photographs of the latest models of this famous motor cycle, which has done so much in war service for the British and Allied Armies. All the well-known types—the War Office model, the touring model, the lady's model, and the 4 h.p. machine—are illustrated and described.

Birmingham Municipal Bank.

The Birmingham Small Arms Co. recently offered the sum of £100, divided into six prizes, to be drawn for by depositors in the Birmingham Municipal Bank. The draw, which took place recently, resulted as follows: First prize, £50, J. W. Snead; second, £25, F. Atkins; third, £10, C. Sprason; fourth, £5, Amy Armstrong; fifth, £5, F. F. Ellis; sixth, £5, G. H. Dangerfield. Councillor Hallas attended the draw, and addressed the workpeople on the value of thrift.

Conversion Tables.

We are in receipt of two useful conversion tables from the Hoffmann Manufacturing Co., Ltd., Chelmsford, Essex, manufacturers of steel balls and roller and ball bearings. These conversion tables are for the purpose of converting inches to millimetres, millimetres to inches, also pounds avoirdupois to kilos, grains to grammes, and metric tons to tons. In view of the possibility of the metric system being adopted in this country, and of the large extent to which it is used in modern engineering, these conversion tables should be of great value.

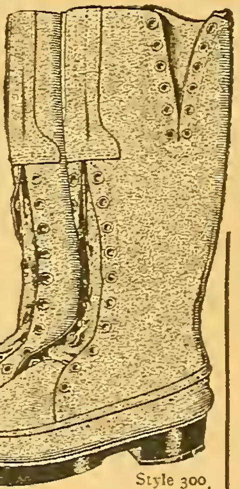
SPECIAL OFFER
TO ALLOTMENT HOLDERS
and all Land Workers.

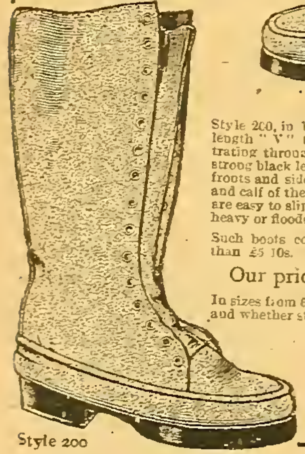
Allotment Holders and all who work on the land require stout waterproof boots that will withstand hard usage, and keep their feet warm and dry on rain-soake soil. It is impossible to obtain such boots in the shops except at exorbitant prices. Every man doing work on the land should therefore seize the present opportunity of obtaining a pair of really high-grade

WATERPROOF BOOTS FOR LAND WORK.

These boots are guaranteed to be repaired Field Trench Boots, made of the finest Government leather with stout new soles and heels, and guaranteed sound uppers of first-class workmanship, material, and finish.



Style 300.



Style 200

Style 200, in brown leather of superb quality, have full-length "V" tongues, which prevent the wet from penetrating through the lace-holes. Style 300, in stout and strong black leather are pull-on boots with special lace up fronts and sides to ensure a comfortable fit at the ankle and calf of the leg. Both have pull-on loops at back, and are easy to slip on and off. They are ideal for rough use on heavy or flooded soil in bad weather.

Such boots could not be obtained in the shops for less than £5 10s.

Our price **21/-** postage 1/- extra.

In sizes from 6 to 10. Send Postal Order and state size, and whether style 200 or style 300 is required.

WHY?

Why do our advertisements pay? Not only because we make them as attractive as possible, but because we make our terms of dealing as attractive and as fair as possible, and because the prices at which we sell our goods are also attractive.
Write for full lists of 150 machines and 50 cars, and ask for details of our instalment scheme, by which you can reserve a good new or second-hand machine for after the war. We also undertake exchanges.
Remember that we will exchange any machine bought within three weeks of purchase if not suitable.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

DRUID

MARK II

Very few motor cyclists can say, on reviewing past jaunts awheel, that these were not rendered most comfortable and smooth by virtue of the presence of DRUID Spring Forks.

In the "science" of their design and construction lies the secret.

A. DREW & Co., Ltd.

TYRES.

THE Economic Tyre Co.—Special clearance lines, carriage paid; approval against remittance.

ECONOMIC.—26×2¼ Kempshall, anti-skid, 17/6; selected covers, 21/-, listed 42/6; Kempshall non-skid, 27/6; selected 32/6, listed 53/4.

ECONOMIC.—650×65 3-rib Clincher Dreadnoughts, 40/-, listed 55/-; Kempshall anti-skid, 30/-, listed 57/9.

ECONOMIC.—28×3 Kempshall, anti-skid, 30/-, listed 69/3; Avon 3-rib, 39/6; A Won, 42/6.

ECONOMIC.—24×2¼ De Luxe, 30/-, listed 39/6, for 2-strokes; 26×2½×2¼, 35/-, listed 46/3; 26×2½, 32/6, listed 44/6.

ECONOMIC.—26×2½×2¼ tubes, for 2¼ rims, 7/6, listed 11/6; 26×2½, 6/6; 650×65, 8/6; belts from 9d. per foot.

ECONOMIC Tyre Co., 137a, Lewisham High Rd., New Cross, S.E.14. 'Phone: New Cross 1393. [5462

TYRES.—See Bancroftian Advertisement under Miscellaneous. Stelastic, Pedley, Kempshall, Hutchinson; extraordinary prices. [0845

ROM Combination Cover, 12/-; Max ditto, not used, cost 54/-, sacrifice 30/-; two butt tubes, 4/- each; all 26×2¼.—65, Linden Av., Thornton Heath. [5635

BASTONES.—Special clearance lines. Michelin heavy Trident covers, B.E., 26×2¼, 19/6; ditto, W.E., 17/6; Michelin, light, B.E., 26×2 8/6, 26×2½ 11/-; tubes, 26×2 4/9, 26×2¼ 5/3, 26×2½ 5/9; all sizes covers and tubes in stock.—228, Pentonville Rd., King's Cross, London, N.1. [5605

ELITE Rubber Company, Ltd.—We have the following special clearance lines in motor cycle covers, tubes, belts, etc. These goods are quite new. Any article sent on 7 days' approval against remittance. A 3/- outfit sent free of charge to all purchasers of covers and tubes, as advertised, on orders exceeding £1.

ELITE.—26×2¼ Avon Sunstone, 35/-, list 52/6; tricar 27/6, list 40/-; Stonehenge, 21/-, list 29/6.

ELITE.—26×2½ Avon tricar, 30/-, list 43/-; Stonehenge, 22/6, list 32/-.

ELITE.—650×65 Avon 3-ribbed, heavy, 33/-, list 48/-; extra heavy, 38/6, list 56/-

ELITE.—26×2¼ Kempshall heavy anti-skid, 19/6, list 37/6; 28×3, 27/6, list 57/6.

ELITE.—26×2½ Kempshall heavy non-skid, 45/-, list 58/6; 26×3, for 650, 42/6; list 78/-; 28×2½, 37/6, list 60/-.

ELITE.—26×2⅝ Pedley, extra heavy, 3-ribbed; 28/6, list 44/-.

ELITE.—26×2½×2¼ Midland, extra heavy ribbed and studded; 22/-, list 35/6.

ELITE.—Best quality inner tubes, 26×2 5/-, 26×2¼ 5/9, 26×2½ 6/6, 26×3 6/6, 28×2½ 7/6, 28×3 10/6; butted 1/6 extra.

ELITE.—Continental belts, 8ft. 6in.×1in., 10/- each; 7ft. 6in.×⅞in., 7/6 each

ELITE.—Best English make belts cannot advertise name, 6ft.×1in. 1/3 ft., suitable for all countershaft gear machines; also supplied as 2-piece belts, any length, 7ft. lengths of ¾in., at 11d. ft.

ELITE.—Retreading, extra heavy 17/6, heavy 15/-, medium 12/6.

ELITE Rubber Co., Ltd., Head Office 321-323, High Rd., Streatham, S.W. 'Phone: Streatham 1467. Also at 266, Vauxhall Bridge Rd., Victoria, S.W.1 (one minute from Victoria Station). 'Phone: Victoria 6553.—Please address all communications to Head Office, Streatham. [0933

TYRES.

GOODYEAR Covers, brand new, unsoiled, not clearance goods, but brand new all-weather tread, 650×65, list price £3/8, our price 30/-; also 700×80, listed at £3/19/6, our price 35/-; carriage paid on 12 covers.—Percy and Co., 337, Euston Rd., London. 1,000 covers in stock: special prices for quantities. [0738

TYRES by Best Makers; nearly half present prices.—Rubber studded, 26×2½, heavy, 28/6; 28×2½, heavy, 29/6; 28×3, heavy, 33/6; 26×2½ sidecar cover, 16/6; Kempshall heavy anti-skids, 26×2¼, 18/6 each; Continental heavy, 26×2½, 25/-; ditto sidecar tyres, 17/6; Goodrich 26×2¼in. rubber studded (clearance), 24/9 each.—Service Co., 292, High Holborn, London, W.C.1. [5757

PATENT AGENTS.

CONSULTING Patent Agency, 253, Gray's Inn Rd., London.—Free advice. Inclusive charges. [6427

INVENTORS' Advice and Handbook Free.—King's Patent Agency, Ltd., 186, Queen Victoria St., London. [5818

TANKS.

TANKS.—Tanks any shape to order, repaired or enamelled; disc for motor wheels; general sheet metal work; lists free.—Attwoods, 86, Rosebery Av., E.C. Tel.: Central 12445. [5523

SITUATIONS VACANT.

CYCLE Business in urgent need of a smart lad to manage it, able to do cycle repairs and buy and sell stock.—Apply, Box L6,321, c/o *The Motor Cycle.* [5606

WANTED, an experienced motor cycle draughtsman, well up on high-class work; a first-class permanent position with good prospects is open to a clever, earnest man.—Apply, Mr. C. Binks, Phœnix Works, Eccles. [X9835

INSURANCE.

FOR Insurance of all kinds (specially motor), apply, Ernest J. Bass, Insurance Broker, Bishops Stortford. [0693

DREADNOUGHT Motor Cycle Policies at Lloyd's. Low premiums by monthly payments. Before insuring elsewhere write for prospectus issued solely by Roys, Ltd., 199, Piccadilly, London. Tels.: Regent 5878-9. [7734

FINANCIAL.

CAPITAL Required, or partner for motor cycle business.—Box L6,347, c/o *The Motor Cycle.* [5751

A. WANTED.

DOUGLAS, Harley-Davidson, A.J.S., Enfield, Sunbeam, B.S.A., and Morgans purchased for spot cash, not earlier than 1915.—Maudes', 100, Gt. Portland St., London, W.1. [4254

WANTED, a motor bicycle.—Shrublands, Kempsey. [5624

WANTED, late model Henderson.—L., 56, Eton Av., N.W.3. [5758

LIGHTWEIGHT Sidecar, for 2¾h.p. Douglas.—Dr. Hancock, Bentley, Hants. [5706

DOUGLAS, 2-speed, 1914, 2¾h.p.; London district.—Box L6,346, c/o *The Motor Cycle.* [5749

WANTED, combination of recent date.—Particulars to 5, Park Av., Palmer's Green, N.13. [X5050

100 Motor Cycles Wanted, spot cash paid; bring or send, Palmer's Garage, Tooting. [0917

PISTON or cylinder and piston wanted, for 3½h.p. Premier.—Harper, Berkhamsted, Herts. [X4989

WANTED, motor cycle and sidecarrier, also lightweight—Frimley Water Co., Frimley Green, Surrey. [5695

WANTED, combination, A.J.S., Enfield, Sunbeam; lowest.—Parsons, 190, Broadway, Hendon, N.W. [5690

WANTED, fast combination, Harley, Clyno, Norton, Triumph preferred; cheap.—Else, Dimple, Matlock. [X5044

2¾h.p. Twin J.A.P. Engine; particulars and lowest cash price.—Will Moore, Westville, Riddlesden, Keighley. [X5037

TWO Fixed Cups, two adjusting cups, and two cones for Rex 1911 2-speed wheel.—Schoolmaster, Molland, Devon. [X5057

WANT a good combination, must be cheap, and not earlier than 1914.—H. Druce, Apsley End, Hemel Hempstead, Herts. [5686

WANTED, A.J.S., Enfield, or Sunbeam twin sidecar combination; cash waiting.—Collier's Motories, Deal St., Halifax. [5652

WANTED, good up-to-date second-hand accessories; state particulars and prices.—Service Co., 292, High Holborn, London. [X4741

WANTED, a Douglas crankshaft, for 2¾h.p. twin, 1913.—Apply, F. Light, The Royal Oak, Elizabeth St., North Woolwich. [5613

WANTED, planet Roc gear wheel, for 1912 Humber motor cycle.—Chalmers, 75, Sommerville Drive, Mount Florida, Glasgow. [X4779

AUCTIONEERS' ANNOUNCEMENT

Owing to Expiration of Lease,

MR. S. G. CUMMINGS

Has been favoured with instructions to

SELL BY AUCTION

upon the

PREMISES OF THE PHŒNIX SIDECAR MANUFACTORY,

736, Holloway Road, Upper Holloway, London, N., on

TUESDAY, JUNE 11TH, at 11 A.M. prompt,

the

STOCK AND UTENSILS OF TRADE

of this Well-known Firm, comprising:

About 60 complete SIDECARS and SIDECAR BODIES complete with wheels and rims, CHASSIS FRAMES, COMPONENTS, MUDGUARDS, ENAMELLING OUTFIT, FORGES, BRAZING HEARTH, APPLIANCES, etc.

CYCLE AND MOTOR CYCLE TOOLS, APPLIANCES, AND ACCESSORIES.

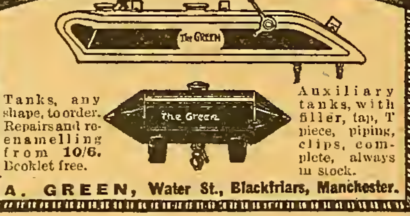
150 HEAVY MOTOR CYCLE NEW COVERS,

200 INNER TUBES,

2 MOTOR LORRIES, OFFICE FITTINGS, FURNITURE, ETC.

Catalogues upon application to the AUCTIONEER, 101, Fulham Road, South Kensington, London, S.W. ('Phone: Ken. 3698), or to THE PHŒNIX SIDECAR CO., 736, Holloway Road, Upper Holloway, N. ('Phone: Hornsey 449).

Petrol & Oil Tanks



Tanks, any shape, to order. Repairs and re-enamelling from **10/6.** Booklet free.

Auxiliary tanks, with filler, tap, T piece, piping, clips, complete, always in stock.

A. GREEN, Water St., Blackfriars, Manchester.

THE BETTER WAY.

Exchange it

Send for our

PRICE LIST OF MOTOR CYCLES,

post free.

WANTED.

WANTED, 3½h.p. Premier, 3 speeds, kick start, any similar make, less power unit.—Musgra Shotton Colliery, Sunderland. [56

WANTED, combination, not earlier than 1915, p fect condition.—Particulars and lowest price, 4 Whitehorse Rd., Thornton Heath. [57

WANTED, sidecar, suitable for Harley-Davidson, g condition; state lowest price and particular Box L6,338, c/o *The Motor Cycle.* [56

WANTED, front wheel, to fit 1914 or later B.S. motor cycle, new, or good second-hand.—Parti lars to Watts, Garage, Lydney, Glos. [X49

WANTED, 2½h.p. 2-stroke engine; state price, da friction Villiers or levers preferred.—Burdon, Fowler Terrace, Hendon, Sunderland. [X50

WANTED, Sunbeam, A.J.S., or Enfield 6-8h.p co binations; cash waiting.—Farrar's Motori Hopwood Lane, Halifax. 'Phone: 919. [47

100 Motor Cycles wanted; bring or send; spot cash.—Palmer's Garage, Tooting. [58

WANTED, T.T. handlebars, for 7h.p. Indian, con tion immaterial if sound; cheap for cash.—Hopkinson, c/o Ramsay, Eton College, Windsor. [57

WANTED, back wheel sprocket, also countersh sprocket, for a 1915 8h.p. Harley-Davidson, 11 Model motor cycle.—Cleale's Garage, Chelmsford. [56

SECOND-HAND Motor Cycle, perfect condition, 4h. h.b.c. clutch, twin Clinchers, 2-3 speeds, kick sta late 1915.—Address, Box L6,337, c/o *The Motor Cy* (D) [56

WANTED, really good machine, 3½h.p. to 5h. must be well-known make, Sunbeam prefere sidecar not objected to.—Box L6,344, c/o *The Mo Cycle.* [57

6h.p. Engine, 50°, complete, less magneto; also t pistons for 3h.p. Enfield; and two springs XPall saddle; deposit.—Sewell, 149, Rockingham R Kettering. [X50

WANTED, drop frame, Druid forks, suitable 7-9h J.A.P.; also P. and M. gear, or countershat whole machine less power unit considered.—Wya Heacham. [57

WANTED, two cylinders, two pistons, induction pi one tappet, in good condition, for 1916 6h.p. N Hudson.—Robert Selkirk, 80, Laidlaw St., Tannochsid Uddingston. [56

WANTED, Douglas, Triumph, or other good ma motor cycle; also powerful combination, conditi immaterial.—Particulars, lowest price, Box L6,345, c *The Motor Cycle.* [57

WANTED to Hire, one or two B.S.A. air rifles, f use at Red Cross fete; would purchase outrig if in good condition and price reasonable.—Jo McAulay, Mid Row, Fairlie. [X50

WANTED, pair mudguards and complete belt ri for Premier 3½h.p., 1914, size of rim 3¼ wi by 9½in. diameter; also pair mudguards for Singe 1914.—Prowse, 43, Horn St., Plymouth. [X50

SPOT Cash for Triumphs, Douglas, A.J.S., Enfield Brough, Nortons, Hendersons, Sunbeam, Zenit Harley-Davidson. Write, call, or 'Phone Holborn 577 —Wauchope's, 9, Shoe Lane, London. [39

PERCY and Co. require at least 100 second-han motor cycles and combinations. Please offer your mount. We offer exceptional high prices. W pay you cash on sight.—Percy and Co., 337, Eust Rd., London. [092

WE are buyers of motor cycles of the following make not earlier than 1914: A.B.C., A.J.S., Broug Enfield, Harley-Davidson, Henderson, Indian, Norto Sunbeam, Triumph, Zenith, and other good makes.—Write, giving particulars and prices, Service Co., 29 High Holborn, London. [X474

WANTED, 3½h.p. Rudge engine and Rudge T. handle-bars, 3-speed gear box with clutch an K.S. suitable for 2¾ Douglas; all must be new, nearly new; send particulars, date, and price.—Bo L6,324, c/o *The Motor Cycle.* [561

MORGAN'S Motor Mart, Sternhold Works, Strea ham Hill, London, require several motor cycle combinations, light cars, etc., for their customers o war work. Machines purchased for cash or sold on commission of 5%. Accessories and parts also wante —Manager (Sales Department), Mr. F. Smith, lat A.S.C., M.T. [X488

SEND Your Motor Cycle to Palmer's Garage, Tootin Wimbledon Station. Cash offer will be tel graphed immediately on receipt of machine. Machin can be included in fortnightly auction without charg if offer not accepted. Reserve price may be fixed.—So address, Palmer's Garage and Auction Rooms, 183-19 High St., Tooting. [091

EXCHANGE.

7-9h.p. Indian Combination; exchange cycle car, sell £40.—H.S., 33, St. Stephen's Rd., Bow, [567

1914 4h.p. Zenith-Gradua, C.B. combination, f higher power solo.—33, Brownhill Rd., Catfor [569

EXCHANGE Morgan, A.C. J.A.P., as new, for goo bike and cash, or sell £100.—C.S., 497, Old Fo Rd., Bow. [563

Air Cooling Problems.

A FORTNIGHT ago we published an article, which should be carefully read by riders, designers, and manufacturers alike, on the important subject of air cooling. The writer points out what serious disadvantages accrue from excessive heat, viz., pre-ignition, generally caused by an incandescent sparking plug point; general loss of power, due to a combination of circumstances; distortion of various parts, owing to the wide range of temperature to which they are subjected (cylinder, piston, valves, valve seatings and valve caps are all liable to distortion); loss of compression, due in part to this distortion and in part to the loss of viscosity of the oil; expansion of gas before entry into the cylinder, with consequent loss of volumetric efficiency; the pitting of valves, especially the exhaust valve, involving much labour in grinding; excessive oil consumption, as much of the oil is burnt and escapes with the exhaust, while the residue is deposited in the engine, not only in the form of carbon deposit on the piston top and in the cylinder head, but on the underside of the piston, whence it falls in flakes into the crank case. This is already a long list, but another important point, not touched in the article to which we refer, remains, namely, the failure of the insulation of the plugs when they reach a certain temperature. Some plugs fail at quite moderate temperatures, and careful tests of this weakness were described in this journal some little while ago.

If the heat were uniform throughout the cylinder and piston but little harm would ensue, even if it were somewhat excessive, provided that the oil were not all burnt. It is the unequal heating of different parts that is so injurious, and it is pointed out in detail that this unequal heating is the result of irregularities in the cylinder casting, lumps of metal, such as valve caps, placed in different positions, the form and thickness of the fins, the cooling draught impinging on the front of the engine, and the internal conditions of induction and exhaust, the former naturally being cold and the latter very hot. To this we may add the fact that distortion, either of cylinder or of piston, is a further source of heat, because it allows the burning gases to pass between the parts and increases the friction between the remaining parts, often seriously.

Something might be done towards improving the draught by means of judiciously placed air scoops. Much can be done to prevent distortion by the adoption of a more symmetrical design of cylinder combined with the use of more suitable metals or alloys. The aero engine owes something to the motor cycle and motor cycle designers—we are glad to be able to record the fact that a most successful aero engine is the product of brains trained in the manufacture of motor cycles—and therefore the motor cycle industry need have no false pride nor foolish scruples about taking a hint or so from the aero engine.

Aluminium cylinders, with or without steel liners, give great possibilities of more efficient cooling to the post-war motor cycle engine. Copper or copper-coated fins offer an alternative system, not by any means to be despised; but it must be remembered that when a liner is fitted the contact between the liner and outer covering or fins must be perfect over the whole surface or local heating and immediate distortion will follow. Pistons of aluminium alloy also seem likely to become more or less general on mounts of the best class.

It should be unnecessary to take down an engine for decarbonisation more than once in a season, and valves should require grinding only at these annual cleanings. If these desirable results are attained it will be, we believe, partly due to the cooling problem being tackled in an efficient manner, though doubtless improved carburation and mechanical oiling will also contribute their quota to the end we have in view—the perfection of the post-war motor cycle.

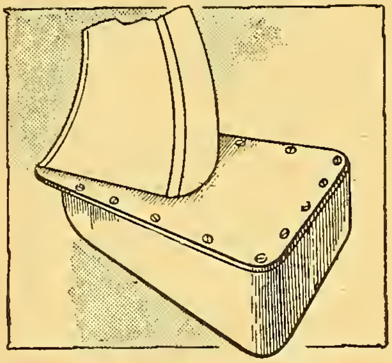
An index to the advertisements in this issue will be found on the page facing the back cover

IDEAS: Useful and Ingenious.

Readers of "The Motor Cycle" are invited to contribute to this page any ideas successfully adapted to their motor cycles. Contributions will be paid for at our usual rates. Rough sketches will suffice

A USEFUL ADDITION TO A FRONT GUARD.

THE front mudguard on some machines with peculiarly shaped horizontal flaps can be much improved by the addition of a U shaped downward extension to the back and sides of this flap, as sketched, which will be found to keep both machine and rider very much cleaner, and its efficiency can be gauged by noticing the amount of mud collected in it during a ride.

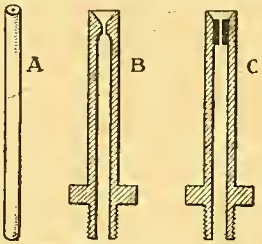


An efficient extension to the front mudguard.

The one actually illustrated was made from 20 S.W.G. sheet aluminium, the bottom edge being beaded round 10 S.W.G. wire and the top edge flanged inwards and secured to the guard by small brass screws and nuts.—F.B.S.

MAKING CARBURETTER JETS.

IN experimenting with a Binks three-jet carburetter, I found a 000 jet too large for the pilot jet, and in reaming out a 0000, which was a trifle too small, spoilt it by making it too large. Having no means of drilling a small enough hole I could not make a new jet; but the following idea solved the problem.



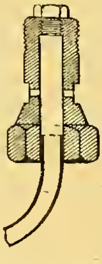
A. Watchmaker's bush wire. B. Spoilt jet. C. Showing the piece of hollow wire in position.

I had in stock some clockmaker's bush wire. This can be got from clock repairers in various sizes, and is drawn brass wire with a minute hole running through it. In this case it was about $\frac{3}{32}$in. diameter, and had a hole which would just take the end of the finest jet reamer I could get—considerably finer than Binks 0000.

I drilled out the end of the spoilt jet to $\frac{3}{32}$in., and sweated in a piece of the bush wire $\frac{1}{8}$in. long, taking care not to block the small hole with solder. The end was then countersunk and the jet reamed out to correct size. The job has proved quite successful.—A. SHARVELL CULLWICK, Wolverhampton.

EASY STARTING.

THE sketch shows a simple alteration carried out on an Amac carburetter which greatly facilitates starting. A hole of $\frac{1}{4}$in. diameter is drilled in the bottom of the jet holder, and a pipe from the auxiliary petrol tank is soldered in. When a start is to be made the tap is turned on, and, as the tank is above the jet, the petrol will force itself out and enable a very easy start to be made. This device has been in use for some time on a Calthorpe-Jap, and is very successful.—N.V., R.N., Dartmouth.



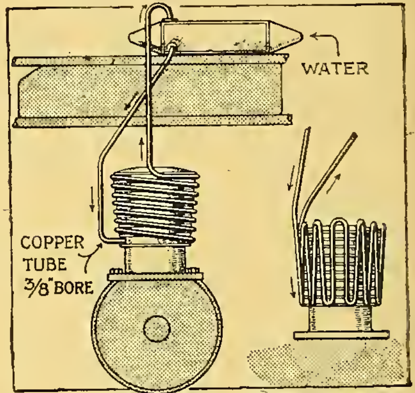
A device for facilitating easy starting.

RESEATING A TYRE VALVE.

THE best plan is to reseat the valve in its original place. Take a patch, making a hole in the centre slightly less than the diameter of the valve barrel. Stretch this over the valve barrel after removing the nut and washer; solution its under side and also that part of the original valve patch on to which it will descend. Apply two thin films of solution and let each dry thoroughly. Then work it down to the valve barrel, being careful not to touch the under side with dirty fingers, and when it is pressed well into place and adhering over its entire surface, push the middle washer down on the valve stem. Screw down the nut, and give plenty of time to dry. Another tip in connection with valves is the rejuvenation of the rubber. By moistening them in warm water and working them in the hand apparently perished valve rubbers can often be utilised.

A PROPOSED CHEAP AND SIMPLE METHOD OF WATER-COOLING.

A SMALL auxiliary tank (such as at present used for starting purposes) is intended to be filled with water, having a copper pipe protruding from the bottom portion down to the engine or cylinder, as shown in the diagram, thence circulating around the cylinder in any suitable manner. The return end of the copper tube would be fixed to the upper portion of the water tank.



A reader's idea for an improved water-cooling system.

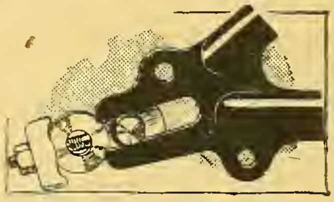
When the engine gets warm, the water in this tube rises, to be replaced by cold water, as in the ordinary water-cooling system.

As copper itself dissipates heat to a larger extent than any other metal, it therefore acts independently of the water as a cooling medium.—H.G.T.

[A similar idea was embodied in the Cayenne motor cycle which was entered in the last T.T. race. The utility of the device is, however, very questionable.—ED.]

CHAIN ADJUSTMENT.

I AM forwarding a simple way of adjusting a chain when the adjuster will no longer act. A washer is placed between the slot for the wheel spindle and the adjuster end. I have used two such for some months with satisfaction.—(REV.) A. E. SAUL.



A useful chain adjuster.

OCCASIONAL COMMENTS

BY 'IXION'

Stumped.

LAST year I ventured the statement that no case of "vibration flooding" with a top feed carburetter had come under my notice. A reader challenges the statement with an eloquent impressionistic story of a dead fly lodging on the needle seat of his top feed. I am ready to learn, I hope, but I do not quite see how vibration caused the dead insect to assume such a position.

Steel Substitutes.

WHEN the motor cycle weights of the future are discussed, people always seem to take it for granted that there will be no advance in metallurgy. The steel industry has advanced by leaps and bounds during the last decade or so: and its advance was due to the pressure of a demand. Among the qualities which our engineering industries demanded in their ideal steels, lightness scarcely figured. So far as lightness has been attained, we have reached it indirectly. We have developed tougher steels, so that a small shaft or pinion of a modern high-grade steel will bear stresses which twenty years ago could only be entrusted to a lump of metal many times as heavy and as large. If we set a 1900 type gear box pinion against its successor of to-day, the contrast resembles that between a water wheel and a motor cycle timing pinion, or thereabouts. The aircraft industry is now shrieking for light metals: and sooner or later the demand will procure a supply. Just as built-up spars of plywood or bentwood will tend to replace heavy spruce and ash timber, so featherweight metals will in time oust weighty steel, just as steel and light alloys have already ousted cast-iron. These tendencies will react on the motor bicycle. If I live to be a really old man, I expect to see my grandson straddling a motor bicycle as bulky as those of to-day, and scaling 50% less; in other words, I will venture a prophecy that the 1960 edition of the, let us say, Triumph roadster will look as big as the 1917 model, but will not weigh more than 112 lb.

The Aëroplane Again.

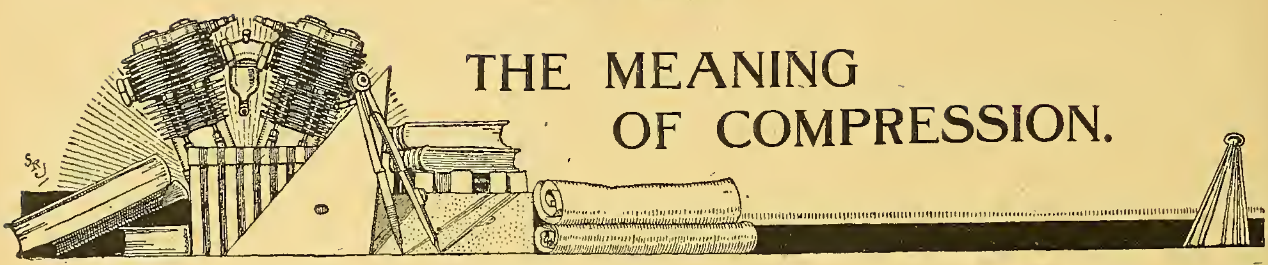
IT is, of course, absurd to pretend that a demand for a given substance directly creates that substance; if it did, I presume $99\frac{3}{4}\%$ of mankind would be millionaires. But demand creates indirectly. Humanity is faced by a new need. Altruism, covetousness, and other factors instantly concentrate many of the best brains on the supply of what will meet the need. At present the aeroplane is the crudest of engineering feats, its engine only excepted. It is made of wood and linen and wire and glue. These materials have two merits—they are cheap to buy, and they are easy to repair after a crash. On the other hand, they deteriorate with extraordinary rapidity. The linen is only usable after numerous coats of expensive dopes and varnishes; and even at that, it is grossly unsuitable for covering surfaces which should maintain an accurate contour, because it sags. The wood is short-lived, and possessed of no great strength; its main strength is derived from the bracing wires, which require prolonged attention from an ultra-skilled staff after every flight. Thus the aeroplane creates an unquestionable demand for a huge supply of wholly novel metals, ranging from a featherweight covering metal for the planes to featherweight tubing for spars and struts. These metals will undoubtedly materialise. Their development will be enormously hastened as soon as "crashes" become exceptional experiences, and cheap repairs cease to be of practical importance. As the aeroplane has borrowed freely in its infancy from the car and the cycle, so in its prime it will repay the debt, with interest added thereto. The very aeroplanes which are the pride of the R.A.F. to-day will excite the incredulous derision of our sons, just as the few surviving boneshakers make us reflect that the pioneer cyclists must have been hardy lads.

Minus One Cylinder.

HERE is a bone for the torque *v.* balance merchants to quarrel over. On reading the recent discussion, some of us deliberately ran several types of twin with one cylinder cut out. The only machine which we found "sittable" under these circumstances was a flat twin. Whilst not particularly pleasant at low speeds, is was infinitely superior to the V's under similar conditions; and when revved up a little it ran so well on one cylinder that an inexperienced rider might not have guessed there was anything amiss with it up to the limit of speed obtainable.

Two-in-one.

I HAVE often said that in one respect the flat twin engine is tantalising. It is the easiest thing in the world to discover a flat twin which can rev. on a low gear, for nearly all flat twins do it. It is not an unknown experience to encounter a flat twin which can pound away on its top gear under a heavy load or against a stiff gradient. The early Douglases were pretty useful at this particular stunt, and I have happy memories of a Brough which habitually indulged in it. But it is quite exceptional to strike a flat twin which can rev. *and* pound, in the sense that I could apply those verbs to my last Triumph, for example. I always tuned it on the middle gear, and knew it was near the top notch if I got 40 m.p.h. "instrument speed" on that gear; with the same tuning it would rush really steep hills on top with a roar, and also clamber up stiffish slopes at one pop a minute. I never yet owned a flat twin which earned quite the same praise. But I hear that the new Raleigh engine combines both extremes to a very high degree. When I get a chance to try this 'bus, I may have more to say. Incidentally, I hope that its spring frame will set the rigid merchants thinking.

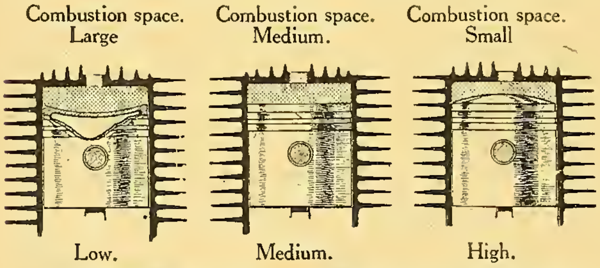


THE MEANING OF COMPRESSION.

MOTOR cyclists may be divided into three classes: (1.) The really skilled, having some knowledge as to the why and wherefore of the internal combustion engine. In practice these men are usually excellent for obtaining niceties of engine tune. (2.) The man of the multitude, who has learnt how to keep a machine in repair, can do his own adjustments, but has insufficient knowledge to enable him to obtain competition results. (3.) The raw novice, who knows nothing beyond starting, stopping and steering his machine, and who regards a companion of two years' experience as an absolute encyclopædia of knowledge.

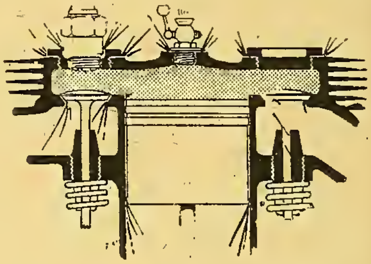
What does compression mean to these three classes? The first knows what it is, and therefore can be eliminated. The second knows what it is when he loses it, and decides to grind in his valves. The third regards it as an illusive something that dropped off at the last hill, and that is why he has to push up the next.

"Compression" is one of those gloriously elastic terms which the engineer uses in one sense and the amateur in another. To the professional it means the actual pressure attained in the combustion space when the piston has attained the top of its stroke. It has nothing to do with burnt valves and oval pistons. It is decided by the ratio between the total volume of the cylinder with the piston at the bottom of its stroke (*i.e.*, the c.c. plus the combustion space) and the combustion space alone. A long stroke engine, however, has not usually a high compression; on the contrary, a long stroke engine is usually a low compression engine, having a large combustion space, for in order to make use of the length of stroke a steady push is required, rather than a violent explosion. By igniting the charge at a comparatively low compression we get this steady push, whereas by compressing it to a very high pressure we get the violent or rapid explosion, and high revolutions thereby made possible. Also we get a tendency towards knocking, and a type of engine with which it is necessary to keep up the "revs."



These diagrams show how the compression ratio of an engine may be reduced or enlarged by the use of a different piston without altering the stroke, and illustrate the meaning of high and low compression.

Coming down to practice it will readily be seen that the best type for pulling heavy loads at comparatively low speeds is the low compression. In this class we may take the P. and M., which is a single-cylinder moderate-powered machine, that has developed on the lines of a hard slogger simply because everyone insisted upon fitting a sidecar to it. It is because the P. and M. is a low compression engine, tuned for hard slogging, that it will tow a heavy sidecar at its own gait almost anywhere, and it will be recalled that in 1914, I believe, the makers fitted a concave piston to enlarge the compression space still further, and thus lower the compression.



Showing the meaning of bad compression as distinct from low compression. An engine in which leakages are shown past the piston rings, valves, valve caps, and sparking plug.

Given low compression, therefore, we have the elements of a hard slogging, hard pulling engine, but it is the combination of compression and valve timing that gives these results. That is, it must not be thought that by fitting thick washers between the cylinders and crank case of a high revving flat twin, and thus reducing the compression, we shall obtain a hard pulling engine which will slog away and never knock when abused. The whole valve mechanism would have to be revised ere such an engine were suitable for sidecar use, and by merely lowering the compression we should simply rob the engine of its revving capabilities, while we should gain very little as regards hard pulling under load.

The Two Types.

By raising the compression of a low compression engine, on the other hand—*i.e.*, by fitting a flat topped piston instead of a concave—we straightaway obtain very much higher revs., and the machine is probably improved for solo use. In the days when I used to ride low compression singles—a vice now abandoned—I always found they were at their best for solo use when they reached that point of carbonisation at which knocking became noticeable with a sidecar, and my last P. and M. was at its fastest after about 1,800 miles of steady riding.

The foregoing, I trust, will assist one or two amateurs to a better understanding of the word compression from an engineer's point of view. A high compression engine is one which has a small compres-

The Meaning of Compression.—

sion space above the piston when the piston is at the top, the length of the stroke being taken into consideration. Then the unignited gases are at a high pressure when the spark occurs, and a violent explosion takes place, giving a quick impulse to the piston but tending to cause a knock should the load be too great. The explosion of paraffin vapour is very rapid, and therefore a very low compression engine is necessary if a knock is to be avoided with that fuel. A low compression engine is one so arranged that the charge in the combustion space cannot attain a high pressure before ignition, and therefore a more or less slow burning explosion takes place, giving the piston a push rather than a kick, and therefore rendering the unit better suited to sidecar propulsion than to speed work.

Volumetric Efficiency.

This does not enter, from the enquirer's point of view, into the question at all. The volumetric efficiency of an engine is nothing whatever to do with its efficiency for its size or for the amount of petrol it uses. An engine having volumetric efficiency of the very highest might be an absolute dud on the road or under bench test, for volumetric efficiency simply means the efficiency of an engine as a pump. That is to say, an engine of perfect volumetric efficiency is one which draws in a volume of gas exactly equivalent to the displacement of the piston stroke, and volumetric efficiency is decided by the size of the valves, the lift given them, and the absence of obstructions in the induction pipe and exhaust. If it were possible to remove the entire cylinder head for induction and exhaust, then we should have an engine of 100% volumetric efficiency—a thing most British engineers aim at, while most Americans ignore it. It is nothing whatever to do with the length of the stroke and the size of the compression space, and therefore it is a mystery quite apart from that of compression.

The Amateur's Version.

So much as regards compression from the engineer's point of view. The amateur need not bother himself about this side of the question, and whether or not his engine is high compression, whether it has a short stroke or a long, need not trouble him in the least so long as he is retaining the compression his pet manufacturer has decided is good for him.

Compression from the amateur's point of view is the stuff that leaks if his cylinder wears oval, or if he neglects his valves, and let us be quite clear on one point. You have no doubt heard it said that so and so's machine, which is a notorious glutton for speed, has no compression whatever, and you at once decide that in the art of timing good compression need not be taken into account. Once I possessed a most extraordinary cycle car, and all my friends were surprised to find that in starting it up one could swing round the handle like a sewing machine. "Good night—no compression at all!" was the usual comment.

Loss of Compression.

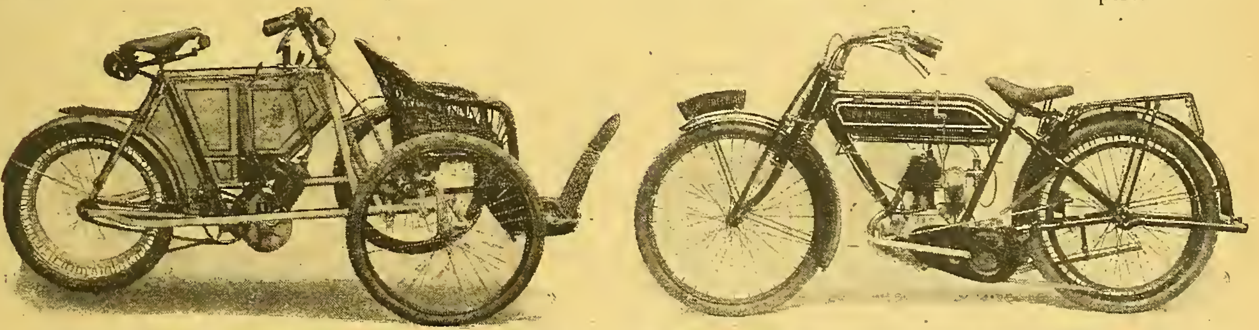
As a matter of fact the compression of that engine was pretty well prefect, and the fact of the matter was that it was an unusually "low compression" engine, having heavy flywheels, and it pulled an unusually high gear.

But—and this is the point the amateur must bear in mind—whatever the natural compression of his engine, every atom of gas lost past the piston or through the valves is *power lost.* These low compression engines which carry everything before them are low compression because their engineers decided thus—not because gas is lost or the volumetric efficiency is low. If you are going to obtain better results you must make sure that none of the charge drawn in is being wasted, and naturally, if your engine is a low compression engine, there is not the same need for glass-faced valves and perfectly bedded piston rings as there is with a high compression engine.

This is one great point on which the low compression engine scores. It is obviously easier to keep in tune than the high compression, and when more than one cylinder is used one can safely consider it the most practical type for general use. CHINOOK.

POST-WAR TRADE.

Another body, having for its object the development of post-war trade, is The British Empire Producers' Organisation, with headquarters at Evelyn House, 62, Oxford Street, W.1. The secretary of this organisation appeals to all trades to formulate a policy which may be placed before the Imperial Conference to be held in June. At this conference representatives of the Dominion Government will be present, and the views of British traders on the following matters could be conveniently presented: (1) As to the measures needed to give to British industries the security necessary for development after the war. (2.) As to the steps necessary to prevent Germany or any other foreign nation from regaining any measure of control of the industries and finance of the Empire.



An old tricar and a modern lightweight, having engines of somewhat similar dimensions. A popular tricar of fifteen years ago had a low compression 2 h.p. Minerva engine, 269 c.c., which, combined with a low gear ratio, could propel a passenger load at slow speeds; a lightweight J.A.P. of 2½ h.p. = 292 c.c., is a mount capable of double the speed with a much lighter load.

CURRENT CHAT

Times to Light Lamps.

SUMMER TIME.

June 13th	9.45 p.m.
,, 15th	9.46 ,,
,, 17th	9.47 ,,
,, 19th	9.48 ,,

June.

This is the time of the year when one used to think of T.T. races and the Scottish and English six days trials.

Cigar Lighters.

We are informed that a smoker was prosecuted recently for illegally using petrol in a cigar lighter. More rumours?

Chichopoxtle.

It is reported from Mexico that a new fruit has been discovered that contains a high percentage of good quality lubricating oil. It is known as Chichopoxtle.

Celluloid Finish.

We have heard of experiments in connection with celluloid covering for the tubing of motor cycle frames. The handle-bars of Rudge machines have been so treated for some years.

Order—or go without.

This, in effect, is the meaning of the new Paper Restriction Order, the details of which are indicated in our advertisement pages. You must either order your copy of *The Motor Cycle* in advance or go without it. Chance purchases at bookstalls will now be very difficult, and at small shops will be practically impossible.

Draw in Aid of the 17th R.W.F. Band Fund.

As a result of this draw, which we have previously dealt with, no less a sum than £350 has been remitted to Col. the Hon. H. Lloyd-Mostyn!

Imagination.

A youthful reader advises us that by fixing a twig against the spokes of his push bicycle he can make a sound almost like a motor cycle.

Motor Cycles in India.

A correspondent writes to us from a tea-planting district in South India as follows: "We have quite a number of motor bicycles and sidecars in this part of the world, which is 4,000 to 7,000 feet above sea level."

Law re Petrol Tins.

At Matlock County Court on Monday, before Judge Macpherson, William Hand, garage proprietor, Matlock, sued W. E. Ganney, of Old Chorlton, Kent, for 3s. 6d., the balance of a sum owing for motor hire. Defendant had, it appeared, handed in seven empty petrol tins to Mr. Hand, who had allowed him 1s. 6d. each for them instead of the 2s. which Ganney claimed was customary, and he therefore deducted the 3s. 6d. now claimed from his taxi bill. The Judge, in giving his decision, said that the plaintiff was justified in only allowing 1s. 6d. for the empty tins as the petrol had not been purchased from him, and he found for plaintiff for the full amount claimed.

Special Features.

THE MEANING OF COMPRESSION.

DANGEROUS TRAMLINES.

ECONOMY OF THE MOTOR CYCLE.

Rustless Iron.

A company has been formed at Shepperton-on-Thames to manufacture aeroplane and other fittings of rustless iron, which is produced by a new process called "doxidising."

Sleeve Valves?

Recently we saw a V twin-engined motor cycle which was as silent as a car. Apparently it was fitted with sleeve valves, but our view from the upper deck of a tramcar did not permit a close examination.

The Spirit of the Pastime.

There is more in motor cycling than in most sports and pastimes. Despite the petrol restrictions and the fact that nine-tenths of pre-war motor cyclists are in khaki, the interest in motor cycle design always shown by our readers is as keen as ever.

Engine Starters.

Since the introduction and abandoning of engine starters by the Merkel and Indian makers we have heard very little of "press the button" devices on motor cycles. It may be remembered the Merkel device was an arrangement of springs, while the Indian was electrical.

A group of motor cyclists and light car owners of the Headquarters Central Detachment Special Constabulary (A.A. Section). The third rider from left is H. C. Horswill, formerly of the Essex Motor Club, a competitor in the London-Edinburgh and other competitions. F. A. Applebee and the late Lt. O. C Godfrey, R.F.C., were both members of this detachment.

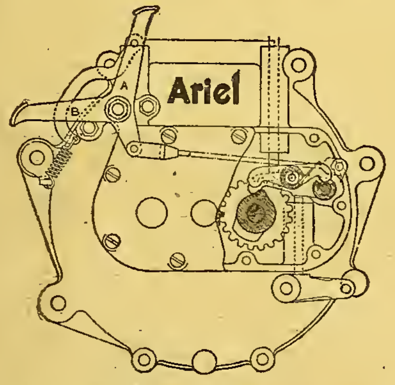
EASY STARTING

OF THE

ARIEL

MOTOR CYCLE

The easy starting of the Ariel is specially mentioned in nearly every letter we receive from owners. The following are a few extracts selected at random.



The Ariel (Patent) Decompressor.

A simple mechanical device—absolutely positive in action—nothing to get out of order. To bring the decompressor into operation the front lever (A) is placed in the forward position, and the rear lever (B) pressed down to bring the engine under full compression.

"Even on to-day's so-called petrol, mine starts at first kick."—W. D. W., Redbourne.

"The other night the bike was left out from 12 a.m. till 8 a.m. in a perfect rain storm. When I got to her in the morning she started up with the first kick."—
Dr. G. H., Shetland.

"It is easy starting and most powerful on hills."—B. S. W., Stowmarket.

"I find the easy starting a great comfort."
—Dr. D. M. H., Bolton.

"The easy starting decompressor is a revelation."—A. B., Ulverston.

HELPING TO WIN
is what the

STURMEY ARCHER COUNTERSHAFT GEAR

is doing to-day.

And after the war is over it will still be "helping to win" the best results from every motor cycle.

Make a note of it.

Sturmey-Archer
Gears, Ltd.,
Nottingham.

In the light

of practical experience the JAMES proves its supremacy over all other British-made machines.

Then why not invest in a

JAMES

for your next new motor cycle?

Our range satisfies all needs, being made throughout by practical riders.

No. 6—4¼ h.p. "Big Single," 3-sp., for Sidecar £79
With James Canoelet Sidecar, £20 extra.

No. 7—3½ h.p. Twin, 3-sp., with hand-controlled clutch, for Solo £79

No. 8—2¼ h.p., 2-st., 2-sp., Lightweight ... £50

No. 9—5-6 h.p. Twin, 3-sp., Sidecar model £84
With James Canoelet Sidecar, £20 extra.

Although mainly producing motor cycles for the BRITISH and ALLIED GOVERNMENTS, we still have a limited number available for civilian use, and orders are being dealt with in strict rotation.

Therefore—if you want one—you should get your name on our "Earliest Delivery List" without delay.

The JAMES Cycle Co., Ld.
GREET, BIRMINGHAM.

London Depot: 23, Holb. Via., E.C.1.
Birmingham Depot: Broad St. Corner.

Prices and Fuel.

These are two matters that cannot be kept too much to the fore nor too frequently discussed. Petrol at over 4s. a gallon (including the tax) and the price of a new sidecar combination in the neighbourhood of £130 make one think hard of the future prospects of motor cycling.

A 3½ h.p. Sidecar Combination Enthusiast.

Recently Maj. Hodgson had his 3½ h.p. Sunbeam sidecar stolen, but, fortunately, it was soon recovered, being found abandoned in a road at Hoxton by a policeman two days after it had disappeared. The numbers were unaltered and the machine uninjured, except that the toolkit, pump, and spare tube were missing. The thief had evidently been taken with panic and had left the combination. Maj. Hodgson left it outside a house in London for an hour, and when he came out it had gone. He tells us that it is the best sidecar outfit he has ever owned, and that he finds a 3½ h.p. combination much more interesting to drive than a big twin. "I have," he tells us, "taken a passenger up Birdlip on it on second without a falter, and that was after a long, hot run. It may interest you to know that I have an F.R.S. lighting set run off the magneto. With the exception of the lamps it only cost £2 2s., gives a wonderful light, and is more reliable than any dynamo set I have ever seen."

Major H. Graham Hodgson, R.A.M.C., winner of *The Motor Cycle* Cup on the occasion of the United Services Motor Cycle Race Meeting at Brooklands, September 4th, 1915.

Manufactured Petrol.

During a lecture before the American Electro-Chemical Society, a Mr. L. B. Cherry, an electrical engineer, stated that it is possible to produce synthetic petrol. Mr. Cherry claims that by producing chemical union of a gas (such as natural gas compound chiefly of methane or hydrogen) with a hydrocarbon (such as paraffin), by subjecting the gas and paraffin vapour to a high frequency high potential electric current, it is possible to reorganise the molecules so as to produce a fuel of the nature of petrol.

British Magnetos after the War.

Many people have expressed anxiety as to how our new industries, such as the magneto industry, will fare after the war when foreign competition is again to be encountered. It is therefore interesting to know that Lord Burleigh's Committee advocates the prohibition of any importation of magnetos from enemy countries after the war and an *ad valorem* duty of 33% on those imported from other countries.

British Magneto Firm's Prosperity.

The Fellows Magneto Co., Ltd., appears to have more than justified the enterprise which gave rise to its inception some eighteen months ago. The dividends recently declared are 9½% on the preferred shares and 15% on the ordinary, and this result has been obtained during a period of only nine months' full working of the new factory.

The King's Birthday Honours.

Among the recipients of Honours of H.M. the King's birthday is the name of Sec.-Lt. George Geoffrey Smith, Royal Air Force, who is appointed a member of the Most Excellent Order of the British Empire for services rendered in connection with the war. Mr. Smith was editor of *The Motor Cycle* up to the time of his joining the Air Service.

Other recipients of honours well-known to motorists are: Commanders of the Order of the British Empire, Mr. Edward Mauger Iliffe, Controller Machine Tool Department, Ministry of Munitions (Mr. Iliffe is of the firm of Messrs. Iliffe and Sons Ltd., proprietors of *The Motor Cycle* and our sister publications); Mr. Edward Shrapnell-Smith, Chairman of the Standing Joint Committee Mechanical Road Transport Associations, Chief Officer controlling the Petrol Executive. Officer of the Order of the British Empire, Mr. Granville E. Bradshaw, the designer of the A.B.C. motor cycle.

A Hydraulic Engine Starter.

A "week-end" experimenter is working hard perfecting a hydraulic engine starter for motor cycles for which he claims that by turning a tap and sitting upon the saddle the engine will be made to start.

"After the War."

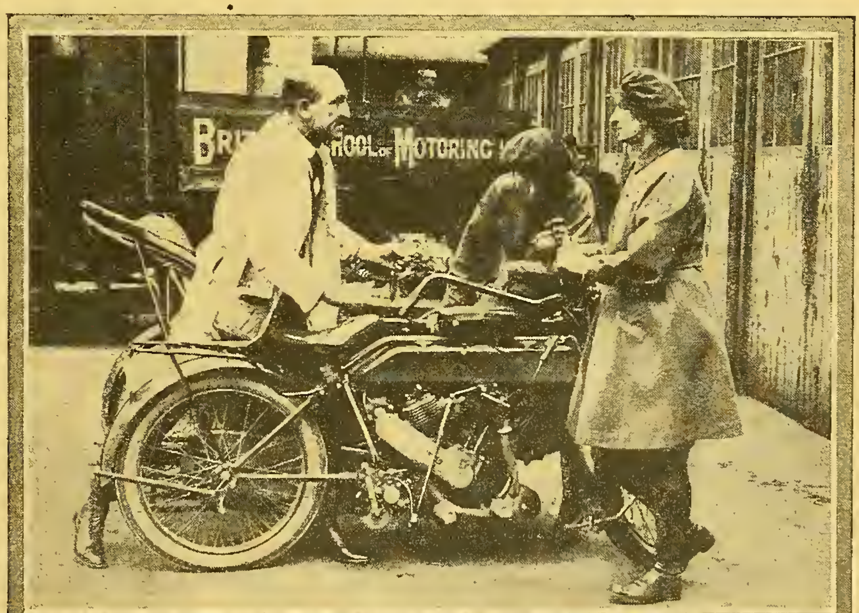
Some time ago we inserted on this page a paragraph on the possibilities, or probabilities, of the petrol situation immediately after the declaration of peace. We stated that, as far as we were aware, Dora would remain in operation till she was repealed.

"Duration of the War."

The subject is revived by an announcement in the dailies of June 6th that a Parliamentary Committee is now in existence to determine the official interpretation of the term duration of the war. In other words the committee has to decide for how long after the declaration of peace shall existing regulations under Dora be continued.

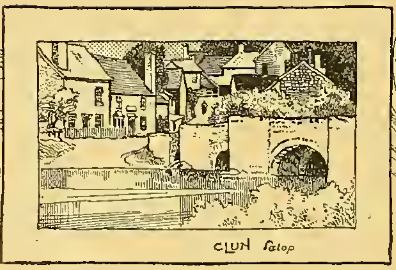
A la the Motor.

Frequently it is said that the motor cycle is a glorified pedal cycle. In America there are cycle models closely resembling the motor cycle, which are in fact, lightweights minus engine. We have also seen a pedal cycle with a neat countershaft gear, which permitted the use of a very neat oil bath case, as the driving and driven sprockets were of the same size.

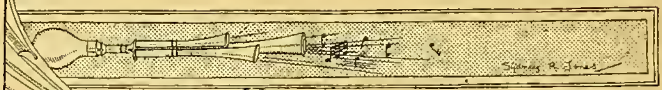


THE HEROINES OF PERVYSE.

—The Baroness de T'Serclaes and Miss Mairi Chisholm, whom we recently referred to in *The Motor Cycle* as having been badly gassed. They are no longer able to carry on their splendid hospital work in the Belgian lines, and are now taking a preparatory course of motor cycling at the British School of Motoring preliminary to joining the Royal Air Force.



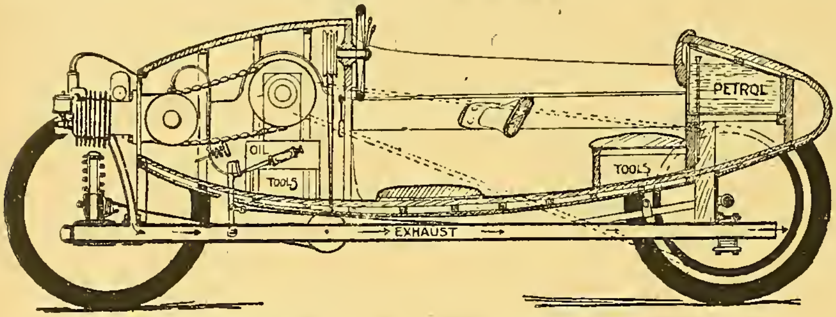
The Very Simple Cycle Car.



Seating Accommodation v. Mechanical Perfection.

THE cycle car was introduced as a motor cycle redesigned to give the driver the same protection from the elements as that enjoyed by the passenger in a sidecar combination. It finished up by being a car in miniature.

At the present time there are many signs of a cycle car revival. In any case, greater interest is being taken in the type than has been the case for several years, and the question naturally arises as to which type of runabout is in the minds of those who may reintroduce this "step between the sidecar and light car."

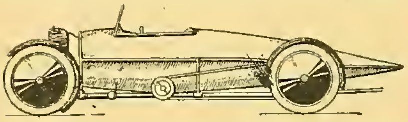


Side sectional elevation of the Gibbons two-seater cycle car, which weighs less than a sidecar combination.

There are three known types of runabout: (1.) The three-wheeler on the lines of the Morgan, the success of which may exert considerable influence over manufacturers. (2.) The belt driven simple cycle car such as the G.N. (3.) A cheaply produced little car following car practice, generally with, say, an air-cooled V twin engine.

A New Type.

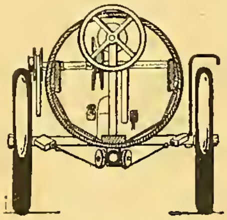
There is, however, still another type, which is not only interesting, but appears to offer certain possibilities for development. Since one machine of this type has been built and run for some 3,000 miles, has a speed of 45 to 50 m.p.h. and a petrol consumption of 85 to 90 m.p.g. with a load of two persons, one is justified in naming the type after its designer and builder, Mr. E. Gibbons; hence the fourth kind of cycle car, which may be considered in the running when cycle cars again are introduced, may be known as the Gibbons type, just as three-wheelers like the runabout from Malvern will always be referred to as being of the Morgan type.



A sporting runabout designed by an Eton boy, embodying many of the features of the Gibbons design.

A solo motor cycle is nine-tenths machine and one-tenth accommodation. With a sidecar combination the accommodation figure is much higher, with a car higher still; with the Gibbons type of runabout one may say that the accommodation element predominates, while the opposite to the Gibbons may be imagined as a 60 h.p. car fitted with a pair of bucket seats.

A car with just bare necessary accommodation suggests that it has been built to propel itself, but because the human element is necessary to manipulate its wheel and levers the designer tardily agrees to allow the driver the use of a seat. The Gibbons type of vehicle is exactly the opposite; the motoring idea is started at the other end of the proposition. Instead of an ingenious machine fitted with a body, it is a body fitted with machinery to propel it.



Front section of the Gibbons cycle car.

To make my point more clear, I will cite the case of the invalid's Bath chair. Here we have a chair to accommodate a passenger. The wheels and other ironwork are necessary, but the chief item in the specification is the chair. That is the Gibbons idea, to build a body for the accommodation of the passengers and fit it to the necessary machinery to propel it. Instead of being a car built around an engine and gear box, with a body added because it was necessary, in this case the body is all important, and it is the machinery that is embodied because it is necessary—a very different thing from usual practice.

At the motor shows, makers display bare chassis and complete cars. The Gibbons idea would be to show bodies and complete cars. There is a great deal of difference between the two, and it arises probably because the average British motorist attaches more importance to the details of the mechanism than the comfort of the body.

As a direct result of this line of thought a little vehicle has been produced which, although having four wheels, weighs considerably less than a sidecar combination with the same mechanical units.

Constructional Details.

Mr. Gibbons's runabout here illustrated has a 3½ h.p. engine and an epicyclic gear and weighs only 16 lb. over 2 cwt. A sidecar machine with such an engine and gear would weigh considerably more.

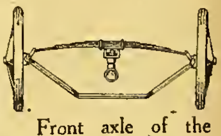
The method of construction permits a very light but strong body being built. Upon thirteen two-ply hard wood hoops are fixed forty laths ¼in. thick and tapering towards each end from the largest diameter of the body where they are 2¼in. wide. These are made a dead fit, and afterwards covered with canvas and varnished.

I think I am right in saying that one or two concerns built sidecar bodies by this process just before the war, and when they were finished a very smooth exterior was obtained.

In the nose of the body is a circular iron plate to which the cylinder of the engine and the crank case are secured.

The only frame member is a straight tube between the axles which also serves as an exhaust pipe.

An Eton boy (E. S. Reynolds) has now submitted a similar design, but whether it is coincidence or intended as a development of the Gibbons runabout is not clear. However, the design shows a racy looking machine, which will appeal strongly to the sporting section of the motoring fraternity.



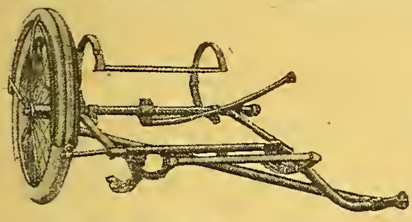
Front axle of the Reynolds design, showing the transverse springing and central frame tube.

The whole point suggested by these designs is that there must be a place in future motoring for a runabout type of machine which weighs no more than a sidecar combination, which should cost no more to manufacture, no more to run (excepting slightly increased taxation), and give the driver a comfortable seat out of the mud, dust, and wet—so adding to the comfort of sidecarring.

A.

A NEAT SIDECAR CHASSIS.

THE American idea of beauty in connection with sidecar body design does not, in any way, coincide with the standard of the Englishman, and therefore the average American sidecar fails to interest the motorist on this side of the Atlantic. However, we think the chassis illustrated here will be of interest to our readers. There are several features which make for simplicity and neatness, among which the design of the frame at the point where it is secured to the motor cycle is particularly good. The diagonal tube from the motor cycle to the sidecar wheel should lend strength, while the weight must be considerably lower than that of many designs which only secure the same results by additional tubing and connections. This chassis is made by the National Machine Co., of Goshen, Ind., U.S.A.



The chassis of the new National sidecar, an American production. The diagonal tube from the motor cycle to the wheel of the sidecar is a noticeable feature.

THE MOTOR CYCLE IN AMERICA.

A Frenchman's Views.

IN a recent issue of *L'Auto* there appeared an article written by M. Vallée-Picaud expressing his views on the motor cycle boom in America. M. Picaud was, before the war, agent for the Clyno in Paris, competed in the Paris-Nice trial in 1913 and 1914, and he was also a competitor in reliability trials held by our principal Allies. When war broke out he served with the French Army as a despatch rider.

M. Picaud points out that the motor cycle has a vogue in the United States at the present time, which is only equalled by that which occurred in England previously, but which France will enjoy after the war. At the moment he is in the United States, and he has certainly studied the question extensively. He enters at some length into the uses to which the motor cycle is put in the States, and quotes instances of even cowboys chasing their herds, on motor bicycles, armed with the famous lasso.

He mentions how much the sidecarrier is utilised for delivering goods, and how keenly the Americans are alive to the fact that the motor cycle can be used with success and far more cheaply than the motor car. He speaks of the excellent work done by the motor cycle mounted police in various cities, and how energetically the dealers and manufacturers carry on their advertising campaigns.

He points out that the American public has not the same mechanical knowledge as the English, that American sidecars are comfortable, but are not so luxurious as those made in Great Britain. Chassis are rigid and solid, and the state of the roads demands this. M. Picaud also expresses his admiration of the way in which a motor cyclist, having bought a machine, can register it and take out the necessary formalities with the greatest ease. The motor cyclist goes to a special office, usually close by where the machine is sold, a declaration is made before a notary, and a tax of $2.50 is paid for a sidecar machine; he then receives a number plate to fix to the machine. The number plate is at the same time a receipt for the registration and a permit to drive. The whole procedure only takes ten minutes.

To hope for such an ideal as this in our own red tape bound country may be too much, but the ideal is perhaps worth bearing in mind. And does it not serve as a hint as to how the oft-discussed tax on pedal cycles might be levied?

To obtain *The Motor Cycle* Regularly after JUNE 24th

Every reader must give a definite order either to a newsagent or to the publishers.

AN official Order has been issued by the Board of Trade which prohibits the system of supplying newspapers on "Sale or Return."

This comes into force on JUNE 24th, and after that date only those readers who have given standing orders can be sure of obtaining their copies of *The Motor Cycle.*

In the past it has been the custom to allow newsagents to return unsold copies and this enabled them to hold supplies for the convenience of travellers and other occasional purchasers.

Under the new Order this custom must cease, and newsagents obviously cannot be expected to risk having unsold copies left on their hands. In future they will take enough copies to supply definite orders only.

Readers who have not already done so should give their orders for "The Motor Cycle" at once and thus avoid disappointment.

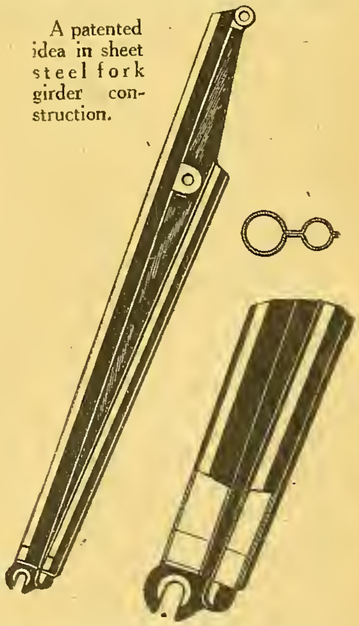
THE OVERSIZE TYRE.

THERE is a marked tendency at the present time for manufacturers to consider seriously the question of fitting larger tyres. A few years ago the 26in. × 2¼in. size was regarded as a standard tyre for a 3½ h.p. machine; then, owing to the increased weight of machines, brought about by the introduction of change speed gears, etc., it was found desirable to increase the size to 26in. × 2⅜in., and finally 26in. × 2½in., or 650 × 65 mm., tyres came into almost general use for machines fitted with countershaft gear boxes and intended for sidecar work. Probably the last mentioned size is the limit, so far as the medium-powered single is concerned, but for 5-6 h.p. and 7-9 h.p. twin combinations we may see the oversize 3in. tyre exceeded.

Certainly riders used to large 700×80 tyres on a heavy combination all declare they will never again think of anything less if they can help it. And war roads—which will also be post-war roads—are an advocate of oversize tyres whose convincing eloquence will take some beating.

SHEET STEEL FORK GIRDERS.

APROPOS the article on pressed steel frame construction by "Mechanicus" in a recent issue, it is interesting to note that Mr. William Starley (whose name is well known in the cycle world) has patented a system of constructing fork girders of sheet steel. From the illustration, it will be seen that each girder is cut out of one piece of sheet steel, which is made to form two tubes with a web between them. No doubt such construction would be stronger and much cheaper to produce than the conventional method of brazing tubes into machined lugs, provided, of course, the output were sufficient to justify the cost of the tools, and there is no reason why other units of the frame, such as back and chain stays, should not be so constructed.



A patented idea in sheet steel fork girder construction.

THE ECONOMY OF MOTOR CYCLING.

Some Examples to Show how an Increased Use of Petrol would aid Reduction in Railway Traffic.

THE recent necessity to travel from the Midlands to the West of England by rail demonstrated once again the remarkable economy of the motor cycle, and incidentally emphasised two points. First, the superiority in speed and business usefulness of road travel over railway travel as at present restricted. Second, the absurdity of petrol restrictions when viewed from the aspect of comparative economy.

Regarding the First Point.

The journey in question was between two large towns, ninety-four miles apart by road. We have frequently covered this route in three and a half hours, non-stop each way, at an expenditure of just over two gallons of petrol, or a total running cost for the return journey (quite possible in one day including three or four hours' business) of about 8s. 6d. solo, or, say, 10s. with sidecar occupied.

Petrol being taboo, we travelled by rail, on the shortest route (115 miles), by the fastest trains now running, in just over four hours, and no return journey was possible on the same day if any business was to be attended to.

The bill was as follows:

	£	s.	d.
Third class rail fare	1	7	6
Increased lunching charges over country prices		3	0
Hotel for one night, say		12	6
Trams and other conveyances, sundries, etc.		2	0
Total	£2	5	0

(or for two people about £4), and the loss of a day into the bargain.

The Second Point.

We were told repeatedly that there was a critical need for conservation of petrol supplies in this country, and a big reduction has been effected accordingly. Now we are being told that there is a further critical need for at least 40% reduction in railway passenger traffic. There can be little doubt which causes most expense to the State, the journey of ninety-four miles by road or 115 miles by rail. The economy to the individual is obvious. Following the arguments through, would it not be an advisable proceeding to allow a freer use of petrol under some system of permits for necessary business journeys to relieve the already congested railway traffic? No question of extra transport of petrol Overseas is involved; the amount coming in appears to be ample for the allotment of a portion to this purpose, and many riders have sufficient in stock for a number of such journeys before making application for more.

By a close co-operation between the Petrol Controller and the railway authorities much might be done to reduce passenger traffic, and particularly season ticket traffic.

A more striking example occurred in a journey between two important Midland manufacturing towns fifty miles apart, or a two hours' run by road. By train it is now impossible to travel in the morning to keep an appointment before midday. As this was imperative, it was necessary to travel overnight, with the consequent hotel expenses. The distance by rail is over sixty miles.

The comparative expenses for the two journeys are as follow:

FIRST JOURNEY.—BY ROAD.

Return journey	188 miles.
Travelling time	7 hours.
Cost—solo	8s. 6d.
sidecar	10s. 0d.

Return journey and business in one day.

BY RAIL.

Return journey	230 miles.
Travelling time	8½ hours.
Cost—solo	£2 5s. 0d.
two persons	£4 0s. 0d.

Return journey and business two days.

SECOND JOURNEY.—BY ROAD.

Return journey	100 miles.
Travelling time	4 hours.
Cost—solo	5s. 0d.
sidecar	6s. 6d.

Return journey and business in less than one day.
Open air and health.

BY RAIL.

Return journey	120 miles.
Travelling time	6 hours.
Cost—solo	£1 10s. 0d.
two persons	£2 15s. 0d.

Return journey and business best part of two days
Overcrowded carriages and unhealthy conditions.

The necessary expenses for meals, being common to both modes of travel, are omitted.

The following suggestion for reducing season ticket traffic is not so unreasonable as it may appear at first. When a regular holder of a season ticket for business purposes on short or medium distances wishes to renew his ticket, the question could be put to him—are you a motor cyclist? Are you prepared to take an allotment of petrol in lieu of a season ticket, and so make your journey daily by road? If he agree, the railway company should make a requisition to the Petrol Control Department to supply Mr. So-and-so with the necessary amount. On the permit or licence could be stipulated the particular journey for which it was granted. In many cases half or one gallon per week would relieve the railway of one passenger.

The progress of various types of locomotion at the present time is shown in an interesting London traffic return recently published from Mr. H. Hewitt Griffin's statistics. While a decrease in the number of motor vehicles on the road is only to be expected under present conditions, it would appear that London of all cities in the belligerent countries (excluding, of course, America) has suffered least. For instance, public service motor vehicles have actually increased in numbers since last year, the figures being 2,042 and 2,036. Similarly trade vehicles have increased from 329 to 340; private cars have decreased from 166 to 149.

The percentage decreases from last year in the case of motor vehicles amount to about 5.58%, and 51.97% for pedal cycles.

THE MOTOR CYCLE AVIATION SECTION

The enormous importance of the Air Service needs no emphasis; it will certainly be a determining factor in the winning of the war. The need for men in every branch of aviation is imperative. There is no class in the community better fitted to become flying officers or air mechanics than motor cyclists, a large percentage of whom are young, keen men with sporting instincts, mechanical knowledge, and plenty of nerve.

In the days of voluntary enlistment we were able to enrol no fewer than 11,000 of our readers in the R.E. Signals (D.R.'s), Motor Transport Section, Motor Machine Gun Service, Tanks, etc., a sufficient testimony to the patriotism of motor cyclists. To-day we feel that we can render no better National Service than that of keeping our readers informed of Air Service developments, and, we hope, stimulating and maintaining their interest therein. Therefore, we purpose to devote some editorial pages of "The Motor Cycle" each week to aviation matters without, however, in any way neglecting the primary function of this journal, namely, the fostering and encouragement of the motor cycle movement and the development of the machine.

We realise, too, that motor cyclists, after the war, will be among the first to take up seriously the art of flying, and so, in endeavouring to perform a patriotic duty now, we are also preparing for the future needs of our readers, who, therefore, will welcome on both counts, we hope, this new feature in our paper and theirs.

Rotaries and Radials.

Those who talk of radial engines when in reality they mean rotaries should remember that although a rotary is a radial a radial engine is not necessarily a rotary. Equipment officers, please note!

◆

"Nibs" on Design.

The technical staff responsible for the examination of British engine and aeroplane designs is principally located at Pen Corner House, Kingsway. Members of the staff are, as a consequence, appropriately referred to as the "Nibs."

◆

Those Big Bombers!

The performances of the American Liberty "airplane," and particularly the engine, are anxiously awaited by the Royal Air Force. Like many British manufacturers in the past, our American cousins have evidently discovered that successful airplanes are not produced quite so easily as "shelling peas."

◆

German Rotary Engines.

The Motor Cycle hinted several months ago that the Germans would ultimately be driven to revise their engine policy and adopt the rotary engine for their fighting scouts. Late last autumn there were rumours that new German scouts fitted with such engines had been sighted well over the Hun lines, and that our pilots were trying every trick to shepherd one or two of these machines across to our side so that an engine could be procured for examination—a common dodge when the existence of a new power unit is suspected. Several of these machines have now been satisfactorily crashed over Allied soil, but the bubble has burst. The engines are either captured Allied rotaries, or very ordinary copies thereof, constructed at the Oberursel works, which represented the Gnôme patents in Germany before the war.

Aero Engine Types.

The air-cooled aeroplane still continues to grow in favour—in this country, at any rate. Meanwhile, the Huns still stick to their six-cylinder water-cooled engines—and may they continue to do so.

◆

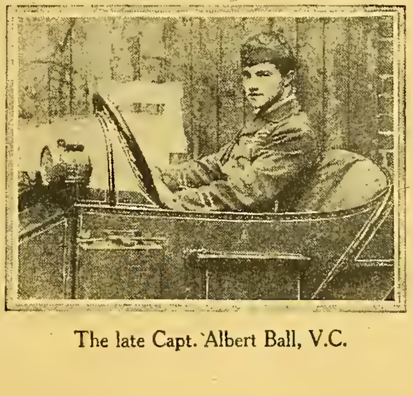
The Man at the Helm.

Sir Arthur Duckham, K.C.B., Member of Council, Air Group, has lately assumed control of the Departments of Aircraft Production. The appointment was necessitated by Sir William Weir's promotion to Secretary of State for the R.A.F.

◆

AIRMEN MOTOR CYCLISTS

The late Capt. Albert Ball, V.C., D.S.O., M.C. (son of Alderman Albert Ball, J.P., Nottingham, a director of the Austin Motor Co), was one of our most famous airmen to meet a brave death at the hands of the Hun. Capt. Ball destroyed over forty German aeroplanes and a balloon. In addition to being a pilot, he was also a motor cyclist. His last mount was a Morgan Runabout, which he used frequently when in England to convey him to various aerodromes. We have, of course, previously given particulars of Capt. Ball's exploits.



The late Capt. Albert Ball, V.C.

The First Internal Combustion Engine Driven Airship.

Paul Haenlein, a German, is reputed to have been the first to propel a dirigible by means of a gas engine. This was about the year 1860.

◆

An Italian Airman and the World's Records.

A sergeant in the Italian Flying Corps established recently what is said to be a new world's record for speed. He flew from Langley Park, Hampton Roads, Va., to Washington in a Spa fighting plane in one hour. The distance is 145 miles

◆

Spare Time Models.

So great is the interest now taken in aeroplanes that several big boys (over military age) of our acquaintance are building models for their sons ranging in age from three months to thirteen years. Those who have not sons usually find a nephew to whom they can *promise* the finished article.

◆

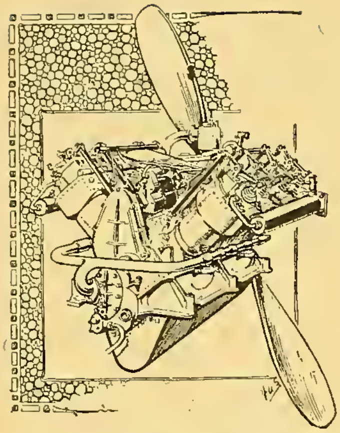
Night Landings.

One of the greatest difficulties in landing at night is to be dead certain that the machine is gliding level and will touch ground with both wheels simultaneously. Should one wheel touch before the other the undercarriage will crumple up, and one wing hit the ground a terrific blow.

◆

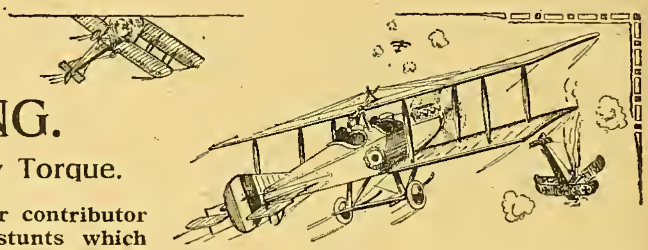
The Monoplane.

The monoplane is reappearing in combat over the Western Front. When the war began, France had many Morane "parasols" in commission, but they were soon discarded. An improved Morane has been recently tested, and its climbing ability and speed have found favour. To give the pilot an unhampered view, the planes in the new model are placed some distance above the fuselage.



STUNT FLYING.

PART IV. By Torque.



In this instalment our contributor deals with a set of stunts which commence with levering the machine over on to one wing tip.

We have already seen that as *surprise* is often the decisive factor in ground warfare, so in aerial fighting it is desirable to keep the enemy guessing about one's intentions. The loop, which has already been dealt with, is a stunt which lends itself to two or three different ruses. Much the same applies to a set of stunts which open with levering the 'bus over so that one wing tip points skyward and the other groundward, the planes exchanging their normal horizontal position for the vertical. A manœuvre which commences in this fashion may develop into at least three separate stunts, namely:

(1.) The vertical bank.
(2.) The wing-slide.
(3.) The roll.

In the first place, there is not the least difficulty in making a modern scout aeroplane stand on its wing tip, so to speak. The earlier aeroplanes were fitted with lateral controls—wingflaps (ailerons) or wing-warping gear—which were just sufficiently powerful to furnish the control required for normal flights, *i.e.*, to effect a rational turn, or to correct the lateral balance. The modern scout has lateral controls which will turn it bodily over in a couple of seconds, and, according to the fashion in which this enormous leverage is employed, one or other of the above trio of stunts can be performed.

For example, a glance out of the tail of a pilot's eye or the rip of bullets tells him that a Hun has caught him unawares, and he may wish to attack the aggressor. He is tail-on to the Hun, and he cannot attack until he is head-on, as his own guns only fire forward. If he thrusts the joystick sideways to the correct degree, the machine will cant over through 90° till its planes are vertical: and if he further uses his rudder, the 'bus will be wrenched round in a vertically banked turn. This turn may be continued through a full circle or part of a circle, as circumstances or Fritz's conduct may dictate. For example, if Fritz blunders straight on, desiring to avoid battle since his first swoop has failed, a vertical bank through a full circular turn will reverse the positions of the two machines, and the Britisher will now be on the tail of the Hun.

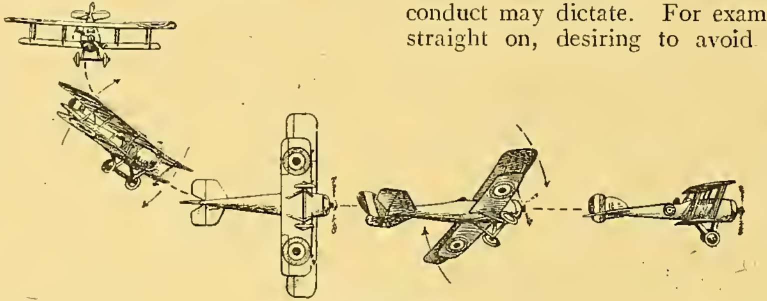


Fig. 1.—Vertical bank.

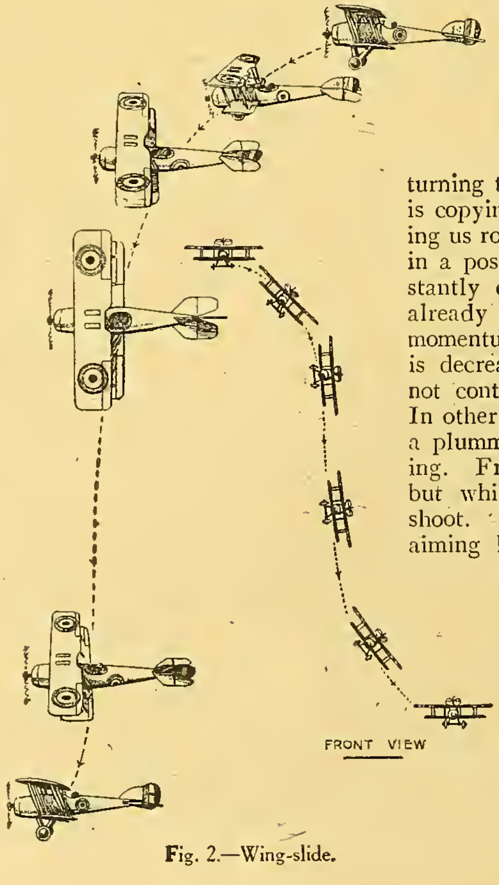

Fig. 2.—Wing-slide.

On the other hand, if Fritz has full stomach for a fight, and banks round after us, we are no better off than when we started to bank. He is still on our tail, and possibly has never ceased fire. Something must be done very quickly. Suppose that after turning through 180°, we realise that Fritz is copying all our movements, and following us round. Our planes are vertical, *i.e.*, in a position in which they furnish a constantly decreasing lift. If we have not already dropped, we owe the fact to our momentum round the turn. The momentum is decreasing rapidly, and if the turn is not continued, a wing-slide is inevitable. In other words, the machine will drop like a plummet, with the lower wing tip leading. Fritz can wing-slide too, if he likes, but while he is wing-sliding he cannot shoot. He can only aim his guns by aiming his fuselage at us: and a wing-sliding machine, though perfectly under control in the sense that it will not "crash" provided there is plenty of room between it and earth, is not under such control that its pilot can line up his sights till the slide has ended.

It is now clear that the vertical bank is a stunt which enables a pilot to change *direction* very rapidly, without any loss of height worth mentioning. On the

Stunt Flying.—

other hand, a wing-slide is a very fast type of *descent.* I have no space in which to work out a detailed comparison between wing-slides and other fast descents, such as the various kinds of dive. It is enough to point out that the path of descent varies according as a spin, a vertical nose dive, a tail-slide, or a wing-slide is employed, and that it is very useful to hoodwink an assailant by having several modes of descent up one's sleeve.

Still more violent or continuous use of the lateral control will cause the machine to "roll," *i.e.*, instead of poising itself on its lower wing tip, it will throw a side somersault whilst continuing to travel forwards. This movement is clearly shown in the sketch on this page.

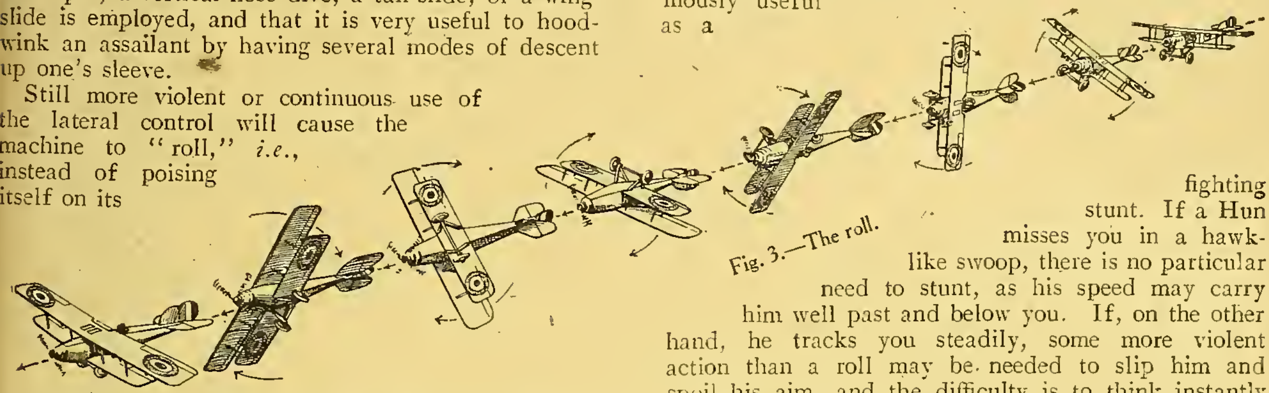

Fig. 3.—The roll.

The Roll.

At one moment the left-hand wing tip is pointing vertically downward. A second or so later the machine has turned over on to its back, lost a little height, and swung a trifle to one side of its original course. A second or so later still, the right-hand wing tip is pointing vertically downwards, the machine has dropped still more, and has rolled still further off its original line of flight. It is tumbling sideways head over heels, like a rabbit shot in mid career. It cannot be pretended that a machine offers a very easy target in the midst of such gyrations. Still, the roll is not enormously useful as a fighting stunt. If a Hun misses you in a hawk-like swoop, there is no particular need to stunt, as his speed may carry him well past and below you. If, on the other hand, he tracks you steadily, some more violent action than a roll may be needed to slip him and spoil his aim, and the difficulty is to think instantly of the most suitable method of eluding him. Every tiniest moment of time is of importance in these encounters.

It should be noted that if it is not possible or desirable to terminate any of the above manœuvres by levering the machine back on to a level keel, the pilot throttles down his engine and puts his controls in neutral. The stunt should then resolve itself automatically into a glide. A crack pilot can usually assist the recovery by the use of his controls.

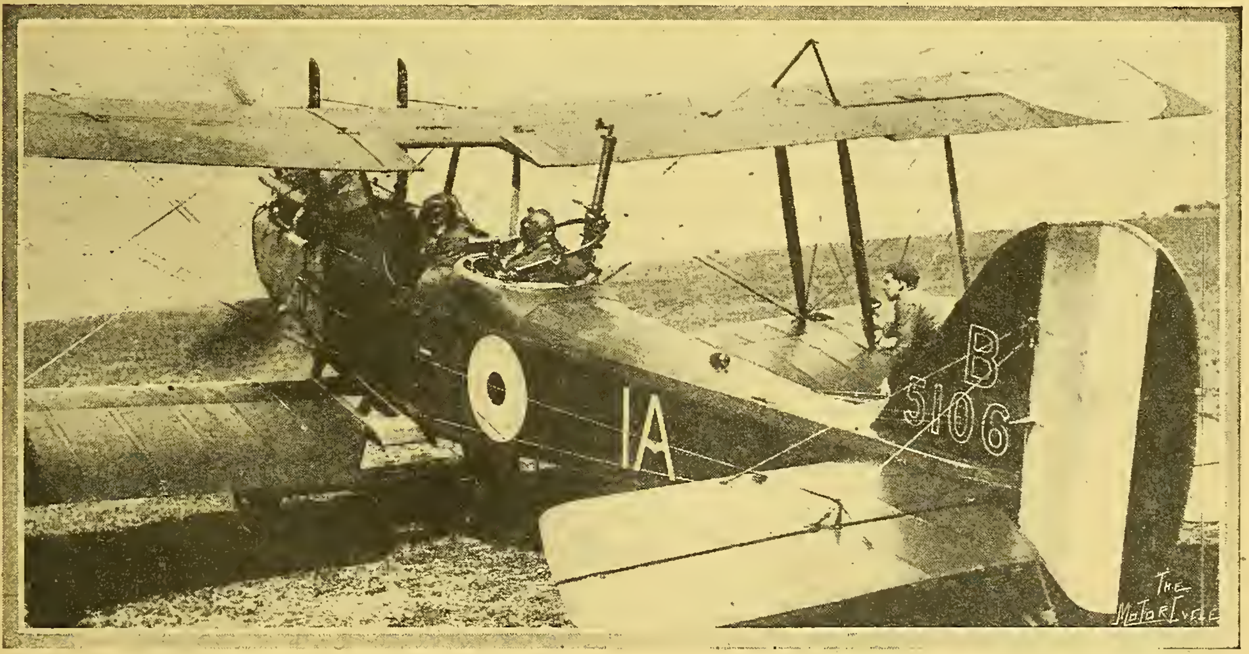
OUR AIRMEN ON THE WESTERN FRONT.



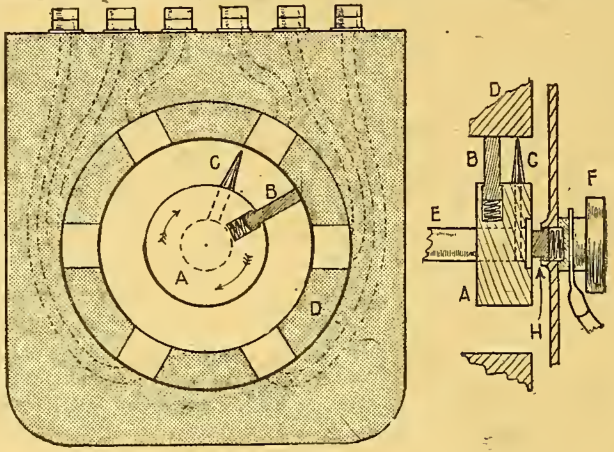
A British aeroplane on the Western Front about to start off for the German lines to work in conjunction with our artillery and infantry. (*Official.*)

THE "BOOSTER" MAG.

How Large Difficultly Swung Aero Engines are Started.

I WONDER how many of our readers have heard of a "booster mag." It is a special type of magneto employed for starting aero engines. Only the largest land engines and most seaplane engines possess electrical or compressed air starters: and "swinging the prop." of engines exceeding 200 h.p. is no great fun. It is obviously possible to get a fine spark out of any magneto, if it be disconnected from an engine and its armature is spun by a small handle. This is how the booster mag. is used. It is mounted in the cockpit, and the pilot spins its handle when the "ac-emma" (air mechanic) has filled the cylinders with gas, and put a cylinder on the firing compression. The current generated in the booster mag., which resembles an ordinary single-cylinder motor cycle magneto, is led by a cable to the distributer of the "service" magneto, mounted on and driven by the engine, and the "booster's" current is utilised in the distributer of the service magneto. Two special fittings are necessary. The booster current cannot be fed to the service rotor, for it would take the easiest path to earth *viâ* the H.T. winding, in preference to jumping a plug gap under compression. Secondly, as the piston of the engine is stationary, a much greater spark retard is necessary than the service magneto provides. These little points are easily managed. The booster cable is attached to a terminal on the centre of the distributer cover, and this terminal is connected by a rubbing brush to the service rotor. The currrent is not conducted to the service brush on the rotor, but to a steel point at the trailing edge of the rotor. Being set behind the service brush, this steel point has a good many degrees of extra retard, and the fact that it does not touch the distributer contacts is of no account, as the booster mag. is being spun pretty fast, and its spark can jump the gap. If everything is in order, the biggest aero engine will start easily on a booster mag., thus saving the air mechanics much exertion and a little danger. It also enables a pilot who has made a forced landing to get away again without the help of men to swing the prop.

TORQUE.



The "booster" magneto, a special type employed for starting aero engines.

A. Rotor.
B. Brush making contact with brush path.
C. Steel point connected to booster magneto; with small jump spark gap.
D. Brush path with six contacts.
E. Rotor spindle bringing current from Service magneto.
F. Terminal of lead from booster magneto.
H. Brush rubbing on brass disc in rotor, and connected to steel point.

D'ARTAGNAN IN THE AIR.

The Charmed Life of a French Airman.

APROPOS of the recent bestowal of the rosette of the Legion of Honour on Charles Nungesser, the French "ace," who has thirty-six victories to his credit (and who has been seventeen times wounded), there are many points of interest in the career of this plucky pilot not generally known. He is one of the few men who have been awarded the Médaille Militaire after less than a month of service. After a lurid career in the Far West of America, he returned to France, and enlisted in the Hussars at the outbreak of war. His superior officer was badly wounded in a nasty little scrap. Nungesser laid in wait at the angle of a road, and by good shooting succeeded in disposing of four German officers who were in charge of an approaching staff car. He impounded the car with all the verve of a d'Artagnan, and drove his officer back to headquarters. In his ragged and dejected state there was no chance of his being received by the general, so he blandly proclaims that he is a spy, and demands to be conducted to "*le Chef.*"

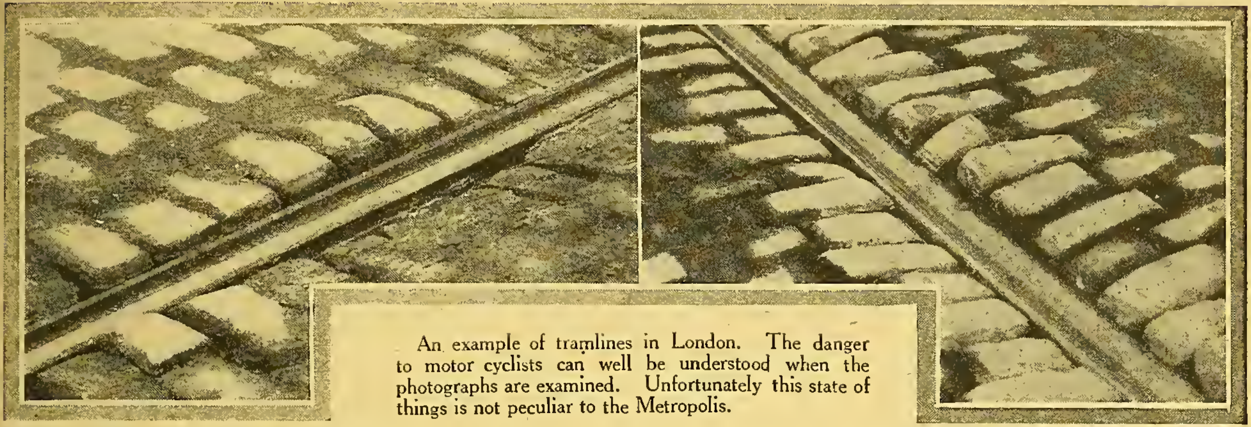
Follow explanations, felicitations, and the military medal, as a map found in the car furnishes valuable indications of German intentions with regard to Paris. Such a man could not long be kept out of the aviation service.

He has had frightful falls: on one occasion he was picked up with a broken leg, innumerable contusions, and yet another frightful wound, his palate transfixed by the control lever. Another man would have been killed outright, but, thanks to a phenomenal constitution, and his double dentition which saved his jaw, he was brought back to life. For three months he was laid up, fretting at enforced inactivity while his fellows were fighting for dear life at Verdun. He decided to go back. Remonstrance at such madness was unavailing, and he returned, saying, "Before the fortnight I will have my Boche!" Two days afterwards this man who could not walk, save weakly with the aid of crutches, made a flight, and brought down an L.V.G. after a few shots! Inside the week, on a frail monoplane, he tackled a heavy bomber—"aerobus" as he terms it! You see him next taking snaps of the *débris* of his victim in the woods of Hauts-Fourneaux.

Never was the gay little rosette better earned.

DANGEROUS TRAMLINES.

A WARNING OF WORN TRAM RAILS TO ALL MOTORISTS.



An example of tramlines in London. The danger to motor cyclists can well be understood when the photographs are examined. Unfortunately this state of things is not peculiar to the Metropolis.

EVER since tramlines were first laid in the public roads and streets they have been the *bête noire* of other traffic. It is perhaps not too much to state that badly laid and neglected tramlines have been the cause of more accidents, minor and major, than anything placed in or on the highways in modern times.

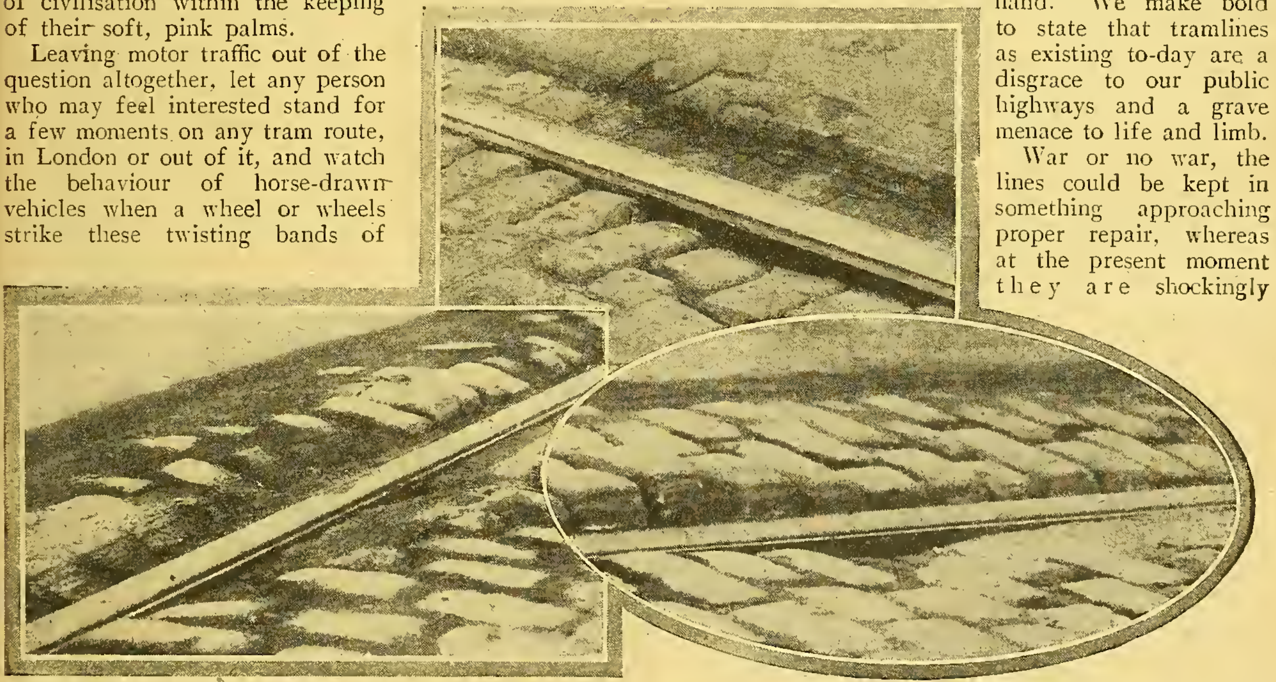
As a motoring journal, we anticipate that there will arise in the minds of the powers responsible for these tramways the opinion that we are biased, that naturally, or unnaturally, we are opposed to every form of travel that has not for its power unit the internal combustion engine. We cannot govern men's thoughts and minds, but could, if we so wished, let the above expected opinion rebound in like manner to those having the "welfare" of the vehicular bully of civilisation within the keeping of their soft, pink palms.

Leaving motor traffic out of the question altogether, let any person who may feel interested stand for a few moments on any tram route, in London or out of it, and watch the behaviour of horse-drawn vehicles when a wheel or wheels strike these twisting bands of "cussedness." It is no unusual sight to see a horse-drawn van proceed for several yards with one wheel locked against the projecting tramlines, the body proceeding at an angle to the fore part of the conveyance, to the undoing of any other vehicle or pedestrian that may be unlucky enough to be in the line of fire.

Some day, perhaps, we may see tramcars running on the overhead trolley system, but without rails laid in the ground. It is too much, we suppose, to hope that they will ever disappear altogether. Once a council or corporation, with ratepayers' money to spend, secures a hold on anything, it is a long, long time letting go, even though the whole thing is a palpable white elephant.

Submitting that we motor cyclists have got to bear it, we absolutely refuse to grin. Quite on the other hand. We make bold to state that tramlines as existing to-day are a disgrace to our public highways and a grave menace to life and limb.

War or no war, the lines could be kept in something approaching proper repair, whereas at the present moment they are shockingly



A further sample—many provincial cities and towns can show just as deplorable examples as these.

Dangerous Tramlines.—
neglected: so bad, indeed, are they that if they were the property of any private person or concern the district authorities would be down upon the owners right away, nor listen to any stories of there being "a war on," or shortage of labour, or anything else.

A glance at the photographs on the previous page will convey some idea of the state existing at the present moment on the routes in and around London. It needs no imagination to gather what would happen when the wheels of any light vehicle such as a motor cycle, sidecar, or light car became entangled in some of the traps shown, or have to cross one at a fine angle. The least to be expected is a very severe wrench to the wheels and axles of a three or four-wheeler, while the rider of a single-track machine would be lucky if he escaped a severe skid and an upsetting resulting in injury of a more or less harmful nature, if not death. In some places where the rails are laid in stone setts the stones stand above the common level of the road to more than half their depth, while at the same time the metal of the rails has sunk an equal amount, and on most routes these bad places occur every few yards.

That the companies know of this deplorable state of affairs is shown by the fact that on many routes men are busy filling up the depressions with loose sand, thereby covering and hiding the pitfall and making things worse, for as the wheels plough through the sand they easily displace it, leaving the unfortunate motor cyclist to emerge by a series of acrobatic tricks, or go under.

In the meanwhile there are plenty of old men about capable of such a small job as levelling a few stones and resetting them with a little cement. Failing which the routes should be closed altogether, as would probably happen were they private enterprises.

DOUGLAS SPRING FRAMES.

Notes on the Famous Bristol Firm's Patented Designs of Spring Frames.

IF proof were needed to show that the spring frame proposition is a problem difficult to solve, we should find it in the patent files. Here, too, we find evidence that British manufacturers are now alive to the necessity of insulating the machine from road shocks, and also that *The Motor Cycle* campaign in favour of spring frames is bearing fruit.

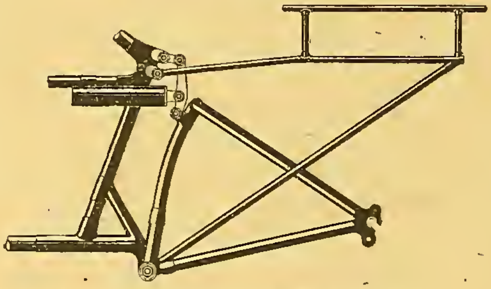


Fig. 1.—A spring frame recently patented by Messrs. Douglas Bros.

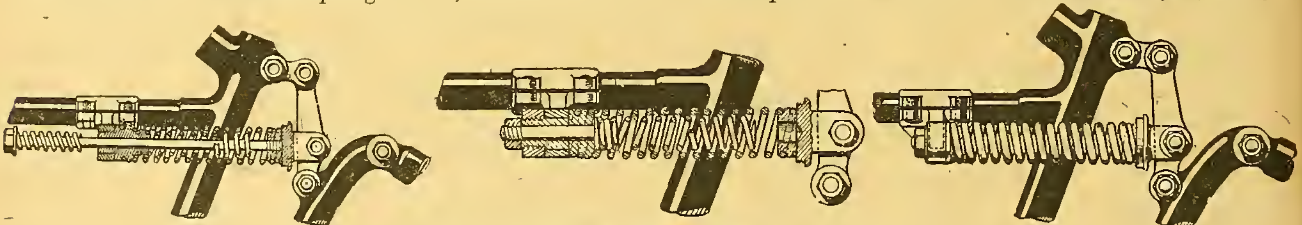
The two latest new machines in the British motor cycle world are the Raleigh and the Matchless. Both have flat twin engines and spring frames. The A.B.C. is another flat twin with a spring frame, while one of the latest models of the parent of the flat twin type—the Douglas—also has a spring frame. It may be remembered that the last mentioned machine has half elliptic cantilever springs. The patent files reveal that Messrs. Douglas Bros. are not content to consider their previous model as finality in spring frames, for we find no fewer than four subsequent patents, in which connection it is interesting to note that, for the time being at least, this Bristol firm is experimenting in a direction apart from laminated leaf springs.

We think that it is generally agreed that it is possible to obtain with coil springs all the results accruing from leaf springs with a reduction of weight. From this it would appear that the coil spring offers very decided advantages in motor cycle spring frame design, as weight is an important factor.

From the various patents granted to Messrs. Douglas Bros., it seems that these advantages are appreciated by this firm, and in fig. 1 we illustrate its latest patent in connection with spring frames.

In this design the coil springs are enclosed in a horizontal casing, the frame for the rear wheel being pivoted at its lower end and shackled at the top. The object of this patent is a design which permits the carrier to be efficiently sprung.



Figs. 2, 3, and 4.—Douglas springing patents of varying dates.

Figs. 2 and 3 are subjects of another patent, and show the principles of the spring action of fig. 1. It will be noted that the springs are anchored at both ends so that they act both in tension and compression. An auxiliary spring is located within the main spring, while in fig. 2 a second auxiliary spring is embodied, which, like the auxiliary spring within the main spring, only comes into action when the main spring has been stressed to some extent.

Fig. 4 illustrates a slightly earlier patent in which auxiliary springs are not included, while fig. 5 is another and earlier patent in which a single and shorter than usual coil spring is used.

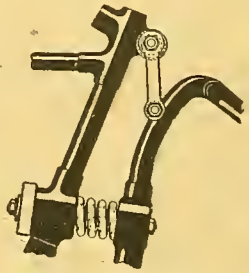


Fig. 5.—A comparatively early patented design.

Letters to the Editor

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

THE FOUR-CYLINDER F.N.

Sir,—I have recently purchased a 1913 5-6 h.p. two-speed F.N. motor bicycle, geared 6 to 1 on high, 12 to 1 on low.

Will any of your readers experienced with this class of machine state if the standard gear ratios for solo work were as low as this, and also what speed I can reasonably expect to get?

I may mention that the cycle is now undergoing a thorough overhaul, and I had not covered more than seven miles previous to taking it down. CANTERBURY.

Thames Haven.

PLUG TROUBLE.

Sir,—*Re* letter from R. C. Meeson in *The Motor Cycle* of May 23rd, page 504, I would strongly recommend him to fit a Reflex plug (White Motors and Accessories). My experience with 4 point Bosch was that it "sooted up." I have used Reflex plugs for both car and cycle work, and found them really satisfactory. As you are probably aware, they are similar to Reliance, only more substantial. If your correspondent decides to fit one, I should be pleased if he would let me know the result. Usual disclaimer.

Douglas. RUDGE.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—Referring to a letter in *The Motor Cycle* of May 2nd by "A Few M.T. Fitters, R.A.F.," I do not think any of these men have been to France. If so, can they let me know the name of any place here where M.T. fitters look after motor cycles, as they say, and are at all times responsible for their being in running order? I should like to say that all motor cyclists out here have to do all repairs but broken frames. I have had nearly two years' riding out here, and have myself done all repairs, bar frames, which are done in the motor cycle repair shop. There are only two of these, and the work is done by M.C. fitters, not M.T. J.H.

B.E.F.

THE RAID ON CUXHAVEN.

Sir,—In the issue of your paper dated April 18th you show a photograph of an Avro biplane with Monsoupape engine. Underneath the photograph is the following: "This type of machine was used in the raid on Cuxhaven in the early days of the war." As a matter of fact, Short seaplanes were used in raid on Cuxhaven, but three Avro biplanes were used in December, 1914, in the raid on Fredrickshafen. Probably Cuxhaven was a printer's error.

You may be interested to know that I joined the M.M.G.S. at Nottingham in July, 1916, and in August, 1917, I obtained a transfer to the R.F.C., and later got my commission. R.A.F.

E.E.F.

MAGNETO HAS A COLD.

Sir,—This experience may be of interest to your readers. In February last year I was on stunt for ammunition, and the journey took me through a rather large French town. The weather, I might add, was of a sort very much undesired by us D.R.'s. It was a journey of about fifty kilometres in a continual drizzle of fine rain, coupled with *beaucoup* slush and mud.

I was jogging along, feeling rather miserable, when suddenly the old W.D. Triumph gave up the ghost. I had a good look round, and found everything was A1, apart from the fact that I could not obtain a decent spark. So I removed the magneto, dismantled and cleaned it, but still it failed to give off the desired effect. This delay put me rather behind time, the motor bicycle was *na poo*, and the message not delivered. So I commandeered the first D.R. that passed to deliver the message. That done, all well and good!

Now I received a sudden brain wave, and came to the conclusion that the magneto had got a cold, or was rather damp. So I sauntered into the nearest French cottage to air it a little round a fire. The result was marvellous; it absolutely put new life into it. I returned to the machine and fitted the magneto, retimed it, etc., and the engine started first kick. PTE. H. F. MIDDLETON.

DIFFICULT STARTING.

Sir,—I read with interest "S.W.'s" letter in *The Motor Cycle* of May 23rd, *re* his B.S.A., and especially as he found it difficult to start up when the engine was cold.

I am riding a B.S.A. 4¼ h.p. sidecar combination, and at first found it difficult to start up, but now I am getting used to its little ways, and can generally get away at the first kick. My machine is a fine goer, and we have some pretty tough hills in this part of Derbyshire, as some of your readers know.

I find the front brake useless, no matter what adjustments I make. A few weeks ago I was puzzled by the "blow backs" in the carburetter whilst running fast, but it pulled A1 on a hill. I am only a novice with twelve months' experience, and I knew not the cause, but I fitted a new plug, and lo, the trouble vanished, and the good old 'bus now runs as sweetly as ever.

I agree with "S.W." that the "amount of neglect it will stand is astonishing," as I have no time whatever for looking things over. R 2531.

Tideswell.

SHOULD SIDECARS BE DETACHABLE?

Sir,—I am a great reader of *The Motor Cycle*. Your paper gives me inestimable pleasure, and passes many a weary hour. The subjects are always very interesting.

I was reading the other day an article in your issue of February 28th concerning the Sociable sidecar. There have been many articles on the same subject previously. I have very much wanted an explanation of this idea of having the chassis of a sidecar integral with the frame of the machine. I cannot see in the least what benefit is derived therefrom. Are we having a car or a motor cycle and sidecar outfit? Which is it to be? Surely, from what I have understood, the reason we have the sidecar outfit is that we can make it, as it were, either a kind of car or solo machine. We are doing away with that advantage entirely, and are gaining nothing. It is neither a car nor a sidecar outfit. The answer will most probably be, "It is much less expensive than a car." True enough; but why not have the same engine fixed to the car itself, and with a small bonnet to cover it, then, instead of having it exposed to the dust and weather conditions, it would be protected. The motor cycle trouble is such an exposed engine (which, in these new outfits, is no longer a cycle!). There is no need to have a motor cycle which cannot be ridden glued to the side. Does this new idea mean to eliminate the old detachable sidecar in time? If so, I am very sorry, and I think many others may agree with me. I wonder if these new outfits will be so popular and the sale so great as is expected after the war. I should be very glad indeed if this can be explained to me.

Aboukir, Egypt. G. B. CODLING, Lt., R.A.F.

[This letter has been much delayed, apparently by submarine.—Ed.]

BRITISH MAGNETOS.

Sir,—Please accept my thanks, as chairman of the British Ignition Apparatus Association, for the article which you gave in your issue of May 16th on the various different makes of British magnetos.

I am convinced that the united appeal has far more weight than any amount of individual booming. It shows that the magneto industry has been tackled in a large way, and that there are ample resources to take care of all the requirements of after-war trade.

At present we are only concerned with removing from the mind of the motoring world the fallacy that Bosch was the only ignition, and we wish to replace it with British.

PETER F. BENNETT.

LONG V. MEDIUM STROKE ENGINES.

Sir,—There has been a deal of controversy on the "stroke-bore ratio" question, and I am under the impression that so far as general efficiency, or, if I may so phrase it, economical power production, is concerned, engineers definitely acknowledge the superiority of the longer stroke engine, and, since its much decried introduction by my company, the practically universal increase of stroke in car and motor cycle engines—excepting where space limitation denies the advantage, as in flat twins, etc.—is abundant evidence of this.

I was pleased, however, to see the letter from Mr. B. Breslau referring to the aid of the long stroke to thermal efficiency, and without any intention of entering the argumentative lists on the subject again, I would nevertheless like to supplement Mr. Breslau's remarks *re* the value of the smaller or more compact combustion chamber of the long stroke engine.

Although heat loss varies as the ratio of surface to volume, the superficial area of the piston-swept cylinder walls exposed to the hot gases is of almost insignificant importance compared with the area of combustion space.

In order that this may clearly be understood, I would draw attention to the following:

1. Heat loss depends upon temperature difference.
2. The period of greatest thermal loss is the period of greatest pressure (or heat).
3. Conductivity of gas increases rapidly with temperature, and makes heat loss at high temperatures much greater than in simple proportion to temperature.

This being so, no very great effort of imagination is required to realise, *first*, that the most important losses are those during ignition or early combustion, as here temperature and pressure are at maximum, and losses at this period *affect the whole of the subsequent stroke*, lowering mean pressure.

Again, the surface of the combustion chamber is exposed during the *whole time* occupied by the stroke, whereas the piston-swept walls are exposed during part of the stroke only, and then to comparatively low temperatures.

Bearing this in mind, the superior thermal efficiency of the long over the short stroke engine seems obvious, the latter presenting more cooling area to the gases when their temperature and conductivity is highest, and at a period when loss affects the whole of the stroke.

It is this fact, quite apart from consideration of mechanical advantages, that accounts for the superior stroke-power and economy of the long stroke engine.

JAS. L. NORTON.

HYDROGEN FROM WATER.

Sir,—The letter on the above subject, in your issue of May 30th, was of great interest to me. I am sure the thanks of the motor cycling fraternity are due to "Pilot," who has given us the secret of a cheap and plentiful supply of fuel, and enabled us, at a most opportune time of the year, to "blind" through the somewhat harassing regulations of the Petrol Controller.

"Pilot's" Commanding Officer should be speedily approached, and requested to forbid "Pilot," in the interests of the engineering and scientific world, to make any more ascents.

He really cannot be spared to tackle such trivial problems as bagging "Huns," who, if they happened to capture him, would soon make use of his obvious genius in chemical research.

Perhaps "Pilot" will tell us, if it is not revealing trade secrets:

(1.) The make of magneto which enables him to utilise the H.T. spark, as well as shorting a considerable portion of output from primary winding through the liquid, at a voltage high enough to pass through pure water (acidulated water, of course, would spoil the nickelled fittings of his tank), and with sufficient wattage to render possible the liberation of some 350,000 c.c. per minute, at normal road speed, of free hydrogen.

(2.) When he first discovered that unidirectional electrolysis was possible with alternating current.

(3.) What device he uses to secure the escape of oxygen only from one of the electrodes coupled to magneto primary.

Barrow-in-Furness. K.A.W.

Sir,—I read with great interest a letter signed by "Pilot, R.A.F.," in your issue of May 30th *re* hydrogen as fuel for motor cycles.

It appears to me that this method of obtaining and using hydrogen is quite impossible. The energy required to split up the water must, of necessity, exactly balance that given up by the hydrogen in recombining with the oxygen in the air.

As the power used in splitting up the water comes, through the magneto, from the engine, there can be no surplus energy to overcome friction of the bearings to drive the bicycle, etc.

I should be glad to hear further details from "Pilot, R.A.F." OBSERVER.

R.N.

Sir,—May I suggest two small improvements to the system by which "Pilot, R.A.F.," runs his motor cycle on hydrogen generated from water by current from the earth terminal of his magneto?

First: Why let the oxygen escape? Why not use the perfect mixture, and so avoid the misfiring he experiences at over 15 m.p.h.?

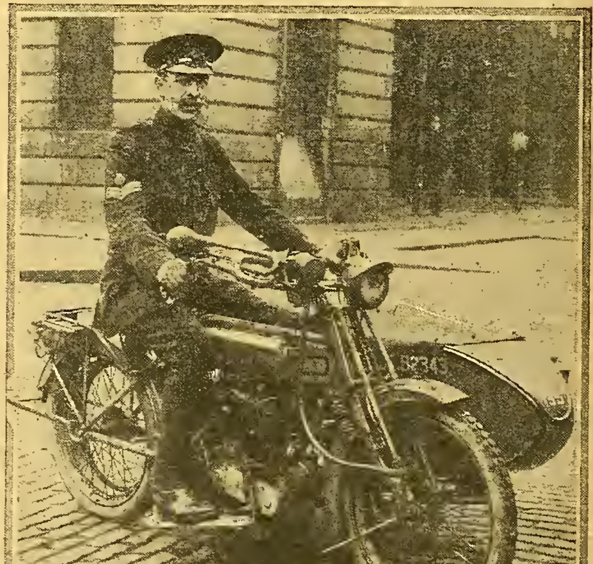
Second: Why not fit a condenser to the exhaust, and thus save the expense of filling up his tank with water?

The Radco, I believe, is fitted with an English magneto; and yet there be they who still prefer the German article!

I sincerely trust "Pilot, R.A.F.," has fully covered his idea, as I believe the patent for a good perpetual motion machine is of considerable value.

Or, Mr. Editor, is "Pilot, R.A.F.," pulling our wing?

F. STEPHENS.



Sgt.-in-charge R. M. Brice, H.Q.C.D. (A.A. Section), on his 8 h.p. Vindec sidecar combination. R. M. Brice is one of our old-time and best known motor cyclists, having competed regularly in competitions from the very earliest days of motor cycling.

Sir,—The letter in *The Motor Cycle* of May 30th by "Pilot" is very interesting, but the following queries arise :

(a.) Why is it the water does not flow into the engine *viâ* the induction pipe?

(b.) As it is necessary to use acidulated water (plain water being a very poor conductor), is the tank of earthenware or lined?

(c.) How is it possible to separate hydrogen from oxygen with an alternating current, *i.e.*, from a magneto?

(d.) Why two wires to "earth" terminal?

(e.) As hydrogen 2 parts, oxygen 1 part, by volume form an ideal explosive mixture, why allow the oxygen to escape?

(f.) As 250 c.f. gas = 1 gal. petrol, say 120 m.p.g., with 211 c.c., escape at 12 m.p.h. = 10 hours running on 250 c.f. gas = 25 c.f. gas per hour = .4 c.f. gas per minute. The usual magnetos give 4 to 6 amps. at 6 volts. What does "Pilot's" magneto give to generate .4 c.f. gas per minute?

(g.) Is "Pilot" quite sure he turned off the petrol after starting up?

I may add that I have tried this "stunt," but beyond having very bad missing in the cylinders and a few stray bubbles on wires immersed in water it was a wash-out.

ILFORDONIAN.

Sir,—We were extremely interested to see, in your issue of May 30th, the letter by "Pilot, R.A.F.," in which he describes his method of using water as a fuel. Nearly two years ago my chum and I thought out this "stunt," but as we had not the wherewithal to try it on our 'bus we had to drop it.

We wonder why your contributor allows all his oxygen to escape, when the two gases are coming over in perfect proportions all ready to his hand? Why not allow them to remix and fire them in the usual manner? There is also less fear of leakage, as no air inlet is required.

We had foreseen the difficulty of the slow evolution of the gases, and proposed to divide the tank in compartments, insulated from one another, with electrodes fitted in each, these being connected in parallel. Of course, to do this properly would really require an extra small dynamo, instead of using the magneto for this purpose and also for sparking. Perhaps this would overcome the difficulty your correspondent speaks of—that of misfiring at over 15 m.p.h.

What we have really been unable to understand is this : The exhaust from an engine running on oxygen and hydrogen is, of course, water vapour. Now if this be condensed and returned to the tank, we have perpetual motion! If any of your readers can throw any light on this phenomenon we shall be glad to hear of it.

Midlothian. TWO SCHOOLBOYS.

[We printed "Pilot's" letter exactly as received, knowing that it would cause interest and comment. At the same time, realising the improbability, not to say impossibility, of the whole affair as described, although it contains the germs of truth, we made enquiries, which have resulted in showing the letter to be simply an effort of the imagination. This most of our correspondents have been quick to perceive.—ED.]

FRAMES EMBODYING THE TANKS.

Sir,—In an article by "Vedette" on "Frames Embodying the Tanks," the writer states "that the only adaptation of this idea has been on recently designed machines," etc. I would like to contradict this, and say that a frame identical with the Premier was designed by Mr. G. Pilkington and the undersigned and constructed by the Rex Co. in 1909.

The idea, however, was considered unsightly, and was not proceeded with. It was, no doubt, like a good many other Rex productions, years before its time.

H. SARGINSON.

DIFFICULT STARTING.

Sir,—As I have seen several letters from B.S.A. riders complaining of difficult starting previously to that of "S.W." in *The Motor Cycle* for May 23rd, it strikes me that my experience may be of use to some.

Over two years ago I purchased a B.S.A. sidecar combination of the standard 4¼ h.p. type, and, a complete novice, commenced my motoring career, with nothing but a fair general knowledge of mechanics to guide me. At once the difficult starting bogey cropped up. *(a)* Starting from cold. *(b)* Starting with the engine hot after an enforced stop on the road.

(a) I had had the usual instructions which every novice receives, viz., "After priming the cylinder with a few drops of petrol, lift the exhaust valve, push the kick-starter vigorously, and when the engine is turning briskly drop the valve suddenly." Why *do* the books give this advice? It is totally wrong. It will get a start—sometimes; but oftener it will not. Many a time I sweated at the job for ten, fifteen, and twenty minutes, especially if the engine was a bit stiff. I was then indebted to a casual letter in *The Motor Cycle* for the correct way, and I have never since failed to get the machine off easily at the first or second kick, provided there was not something wrong with the magneto, such as a dirty contact. The following is the way to do it, and every driver of a single-cylinder engine should take note of it. It will save both perspiration and profanity :

(1.) Inject a little petrol through the compression tap and close tap.

(2.) Press kick-starter pedal till the compression stops you.

(3.) Lift exhaust valve, keeping just pressure enough on kick-starter to carry the piston over the top of the compression stroke, but no further.

(4.) Drop exhaust valve.

(5.) Now give the kick-starter a vigorous push. In this way the piston has to make three complete strokes before again meeting the resistance of the compression, and the flywheel has therefore a chance to get up speed enough to get over the compression. In cold weather it is well to rotate the engine a few turns with the exhaust valve up, after priming, in order to free the piston before trying to start.

(b) Now about starting *hot*. The only difficulty that can be present (if all is in order) is, in brief, *faulty mixture*. You are well primed with instructions as to the proper position of air and throttle levers for starting *cold*. But no one ever has thought of offering the novice the tip that the setting of the air lever which is quite right for a *cold* start is quite wrong for a *hot* start. You start from cold with air closed. But to start from hot you must have air open; if the cylinder is only warm, a little open; if it is very hot, wide open —as wide as the throttle. Before I discovered this simple tip, how I hated being forced to stop for shying horses, or a herd of cattle, etc. More than once I was twenty minutes getting off again. Now I do not care. I would as soon stop the engine to open a gate as declutch, for one kick will start the engine again. And I have come to the conclusion that there is no such thing as difficult starting, at least with the B.S.A., if the rider knows how. But why in the name of all that is perverse do not the books tell one these things? And, may I add, for an absolutely "no trouble" mount the B.S.A. is hard to beat when one knows the machine. In other words, troubles are due to the rider, not to the machine.

"S.W." also complains of the lubrication of the fork spindles. These certainly repay a little attention. It is a good plan to withdraw the pins occasionally, clean and oil them all over before replacing. A very little light oil in the lubricating holes will then keep them running all right.

And one more tip about the weakest point of a motor cycle, viz., the front wheel bearings. Every rider knows the bother caused by water and grit being conducted into the bearings, *viâ* the forks, in wet weather. Here is a complete cure. Cut two circular pieces from any old tin 4in. diameter. In the centre of each make a hole the size of the front hub spindle. Take the wheel off, remove nuts, and slip one of the tin circles on each end of the spindle, up against the cone. Replace the wheel with the tin discs *inside the forks*, and screw up tightly. The pressure of the nuts will cause the discs to assume a saucer shape and concave inwards. Water, etc., running down the forks cannot get inside these, nor can splashes from the tyre in front.

(REV.) WM. F. A. ELLISON.

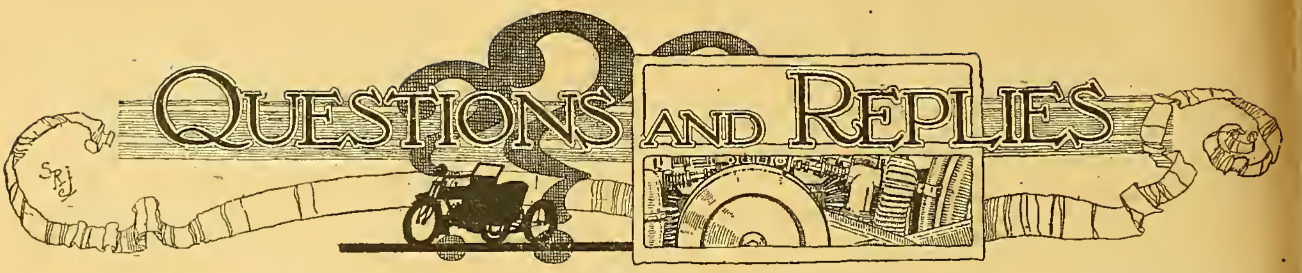
SUMMARY OF CORRESPONDENCE.

We have received the following remarks from Mr. E. B. Ware, chief engineer to Messrs. J. A. Prestwich and Co., regarding the idea for starting a Zenith-Jap illustrated in *The Motor Cycle* of May 16th :

"This arrangement would be unsatisfactory, and we should certainly not recommend it.

"(1.) The J.A.P. gear sprocket is screwed with a left-hand thread, thus any attempt at rotating the engine forward through its teeth will result in the unscrewing of the sprocket and upsetting the timing.

"(2.) The teeth of the wheels are not designed to transmit the power required to start the engine."



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Removing Old Enamel.

I have my motor cycle in pieces, and I am anxious to re-enamel it, so will you please let me know which is the best and the easiest way to remove the old enamel?—E.R.

We should recommend you to burn the old enamel off with a blow lamp, and then scrape and sandpaper the tubes.

Faulty Flywheel Key.

I have a 1914 single-cylinder two-stroke, and recently had to remove the flywheel, and, after replacing it, I started the engine, with the result that the key split in half, leaving one piece in the keyway on the crankshaft and the other piece in the keyway on the flywheel. I have now had the flywheel rebushed as it was somewhat worn, and a new key cut. I then replaced the flywheel, taking care to drive it well up the taper, but as soon as I started the engine the key again split. Should the key be made of extra hard steel?—A.G.

Evidently the key was made of over-hardened steel. We should therefore recommend you to fit a new one, made of something rather tougher and less brittle.

Petrol for Testing.

We are motor engineers and dealers, and have taken out a trade registration for the last eight years. Supposing we advertise a machine for sale in your paper—which we do most weeks—and an intending purchaser wishes us to ride the machine over for his inspection, say a distance of fifty miles, is it perfectly legal for us to do so under the present restrictions? Also, if we purchase a machine from, say, fifty or sixty miles away, shall we be in order in riding it home? Also, supposing we have overhauled a machine, shall we be right in testing it on the road, provided we have our trade number-plates on the machine?—E.B.

The present legal position is that in connection with the *bonâ fide* sale or intended sale of a motor vehicle it can be ridden a distance of twenty miles without a permit, provided the seller has obtained the permission of the police authority of the area in which the vehicle is kept. For distances exceeding twenty miles a special permit must be obtained from the Petrol Controller. As regards testing, this is quite in order, provided you carry your trade numbers and satisfy the usual conditions.

Loss of Power.

(1.) My motor cycle engine has the exhaust valve seating cracked. It goes all right for about half a mile, and then loses power and stops. Do you think the cracked exhaust valve seating would cause the trouble? (2.) I sent the cylinder to a firm to have the crack welded, but it was returned to me with a letter stating that they could not do the work without receiving a certificate from the Ministry of Munitions. (3.) Can I get a certificate from the Ministry of Munitions to have the cylinder repaired?—G.W.

(1.) We think there is no doubt that the cracked exhaust valve seating is the cause of the trouble. (2 and 3.) A priority certificate will only be granted if the owner is doing work of national importance. Application should be made to the Ministry of Munitions, Priority Branch, Caxton House, Westminster, S.W.1.

A Burnt-out Armature.

I shall be glad of your expert advice on the following trouble with a two-stroke motor cycle. After a run of about fifty miles, and leaving the machine standing, on starting up again I found that the shellac on the armature of the magneto had melted and simply gummed up. This meant taking off the magneto cover and cleaning the armature with paraffin. Will you kindly let me know how this can be remedied, and the cause of the melting? Does this happen in all two-strokes with the magneto placed close behind the cylinder?—R.J.R., India.

The trouble which you have experienced is probably the burning out of the armature. This does not mean merely taking the magneto to pieces and cleaning the armature with paraffin, but rewinding the whole armature—a job which cannot possibly be undertaken by an amateur. Either you must send the armature back for rewinding or purchase a new one. Also when removing the armature, instantly place a piece of iron across the poles of the magneto as a keeper, otherwise you will lose all the magnetism; in fact, it would be better to send the whole magneto back to the makers of the machine or to some reputable firm in one of the large towns, such as Bombay. The trouble may have been caused by excessive heat, and we have often heard of similar trouble in the tropics. It is probable, too, that the position of the magneto has something to do with the trouble.

Suction Gas.

Will you kindly tell me if a permit is required for a suction gas apparatus for a motor cycle, and if such an apparatus is on the market?—F.L.

Since "gas" means any form of gas capable of being used for the purpose of driving internal combustion engines, suction gas would come under this category, and would be forbidden to be used except for the purposes mentioned in the Motor Spirit (Consolidation) and Gas Restriction Order, 1918.

Petrol Permits for Munition Workers.

I have tried in vain to obtain a petrol permit. My case is that of a foreman in a munitions factory, and I have to work unusual hours. I cannot use the method of conveyance provided for the other employees because our leaving times do not coincide. I have to walk one mile to the nearest tram service, the journey takes one hour, and I can do the whole journey on a motor cycle in fifteen minutes. You will see I should save threequarters of an hour each way, which is a consideration in these very strenuous times. I have always used a motor cycle for work, and now when I have really more work than ever to do I find it more difficult to get to work and with less time for rest.—M.R.V.

You might try putting your case before the secretary of the National Motor Cyclists' Fuel Union, 70, Abingdon Street, Derby, but we do not think you have much prospect of success. If a tram will take you to within one mile of your work, you may not be regarded by the Controller as deserving of a permit.

READER'S REPLY.

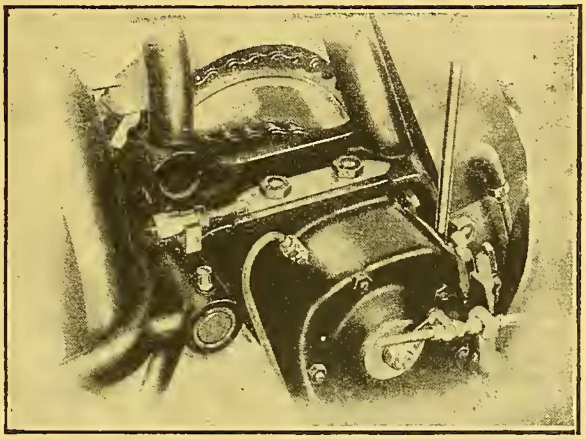
Flywheel out of Truth.

On May 30th "C.S." complains that the flywheel of his 1913 Douglas is out of truth on assembling. With most Douglases the flywheel fits very tightly to the crankshaft, owing to a slight cone. It is usually very difficult to take the flywheel off, and without an extractor the usual method of tapping the crankshaft is useless until the taps become hard knocks. This nearly always results in bending the crankshaft. The remedy is a new crankshaft unless the old one can be straightened. If the flywheel has worked loose, the centre and keyway will be damaged also, and this necessitates a new flywheel.—R.E.C.

A Post-War Feature of the

1918 Powerplus Indian Motocycles

We regret that we are not in a position to supply motorcycles at the present time. But we can send 1918 abridged descriptive lists on application. This applies to Great Britain — only. —



The Powerplus Gear Box showing micrometer adjustment. By turning the nut at the left, the box can be moved to get the correct tension on the short chain.

Order "The Motor Cycle" before JUNE 24

Owing to the Government order prohibiting "returns," newsagents will no longer be able to cater for chance buyers. The only way to ensure getting copies regularly is to **GIVE A DEFINITE ORDER.**

FOR some time past we have been urging upon readers the importance of placing a definite order, either with a newsagent or direct to ourselves, for a regular supply of "THE MOTOR CYCLE," the reason for this being that in view of the paper shortage all chance buying—which leads to copies being left unsold and possibly wasted—must be discontinued.

An official order—which comes into force on June 24th—has now been issued by the Controller of Paper, prohibiting the system of supplying newspapers and periodicals "on sale or return."

In the past it has been the custom with publishers to allow newsagents to return unsold copies, and this enabled them to provide for the requirements o travellers and other chance buyers.

The new Order prohibits this custom, and, consequently, the newsagents, being unable to return unsold copies, obviously cannot be expected to run the risk of having copies left on their hands, and in future they will take only sufficient to supply definite orders.

To avoid the disappointment of being unable to obtain "The Motor Cycle," each reader, who has not yet given a standing order, should at once ask his newsagent to reserve or deliver a copy weekly, or, if preferred, a direct subscription may be placed with the publishers.

ILIFFE & SONS LTD.

PLEASE FILL IN ONE OR OTHER OF THESE ORDER FORMS TO-DAY.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

DVERTISEMENTS in these columns rst 12 words or less 1/6, and 3d. for every words after. Each paragraph is charged rately. Name and address must be counted. s discounts, conditions, and special terms egular trade advertisers will be quoted on ication.

stal Orders sent in payment for advernents should be made payable to FE & SONS Ltd., and crossed & Co.

l advertisements in this section should be mpanied with remittance, and be addressed he offices of "The Motor Cycle," Hertford et, Coventry. To ensure insertion letters ld be posted in time to reach the offices of e Motor Cycle," Coventry, or London (20, or St., E.C.4), by the first post on Friday ning previous to the day of issue.

ll letters relating to advertisements should te the number which is printed at the end of advertisement, and the date of the issue which it appeared.

he proprietors are not responsible for clerical rinters' errors, although every care is taken void mistakes.

NUMBERED ADDRESSES.

r the convenience of advertisers, letters may be essed to numbers at "The Motor Cycle" Office. n this is desired, the sum of 6d. to defray the cost of tration and to cover postage on replies must be added e advertisement charge. Only the number will appear e advertisement. All replies should be addressed . 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☛ DEPOSIT SYSTEM.

rsons who hesitate to send money to unknown persons deal in perfect safety by availing themselves of our sit System. If the money be deposited with "The r Cycle," both parties are advised of this receipt.

e time allowed for a decision after receipt of the s is three days, and if a sale is effected we remit the nt to the seller. but if not we return the amount e depositor, and each party to the transaction pays ge one way. For all transactions exceeding £10 in , a deposit fee of 2s. 6d. is charged: when under he fee is 1s. All deposit matters are dealt with at ntry, and cheques and money orders should be made ble to Iliffe & Sons Limited.

e letter "D" at the end of an advertisement is an atioo that the advertiser is willing to avail himself of Deposit System. Other advertisers may be equally ous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no er to their enquiries are requested to regard the e as an indication that the goods advertised have dy been disposed of. Advertisers often receive so enquiries that it is quite impossible to reply to each by post.

NEW Imperial, 4¼h.p., N.S.U. speed, Bosch mag., just overhauled, splendid condition; owner joined up; £23.—A., 211, Hatfield Rd., St. Albans. [5786

NEW Imperial Motor Cycles, 2 speeds, clutch and kick starter, and lady's models in stock for immediate delivery; trade supplied; no permits required. —P. J. Evans, 91, John Bright St., Birmingham. [5678

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—New Imperial, 1916, 2-speed J.A.P., as new, 29 gns.; ditto, 1915, 24 gns.; both the above machines have been re-enamelled and replated throughout. [5821

Norton.

NORTON Big Four, all chain drive; £82/10; in stock. —Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter. [3524

3½h.p. 1915 T.T. Norton, powerful engine; lowest price 40 gns.—Wauchope's, 9, Shoe Lane, London. [5902

BIG Four Norton, 1916, equipped with lamps, horn, splendid condition throughout; £68.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C.3. [0598

NORTON, 3-speed, clutch, fast, flexible, quiet; first £26 secures; snip; coachbuilt sidecar if required. —Clapham (Motors), King George St., Greenwich. [X5074

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Immediate delivery of the new 1918 Military Model Norton, 4h.p., Sturmey countershaft gears, chain drive; £82/10. [5819

N.U.T.

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—N.U.T.-J.A.P., 1915, 3½h.p. twin, o.h.v., T.T., very fast; 35 gns [5822

P. and M.

P.M., 1913, 2-speed, kick starter, in fine order, T.T. bars, lamps, horn, spares, chains, tube, etc.; £25, or sensible exchange.—Davis, 43, Shern Hall St., Walthamstow, E.17. [5775

Pierce.

PIERCE, 4-cyl., 2-speed, clutch, perfect condition; what offers?—Baets, 10, King's Rd., Richmond. [5776

N.S.U.

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—N.S.U. 1913 3h.p. twin, 2-speed, clutch, attractive lightweight; 19 gns. [5820

HAVING Acquired the entire stock-in-trade of the N.S.U. Motor Co., Ltd., we can supply spares for practically all types of N.S.U. motor cycles. In ordering it is important to submit old parts as patterns.—Eagles and Co., Acton Hill Works, Acton, W.3. [0739

O.K.

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—O.K.-J.A.P., 1916, 2½h.p., 2-speed, hand clutch, 26 gns.; O.K.-Precision, 1914, 3½h.p., T.T., good order, 19 gns. [5823

Precision.

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Precision, 1914, 4h.p., T.T., good order; 19 gns. [5825

Premier.

PREMIER 3-speed Countershaft Combination, like new, 1915; £48.—Peck, 10, Thornbury Rd., Clapham Park, S.W.2. [5875

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Premier, 1913, 3½h.p., 2-speed, clutch, 24 gns.; Premier, 1915, 2½h.p., clutch model lightweight, 23 gns.; Premier, 1913, 3½h.p., 3-speed combination, 29 gns.; Premier, 1914, 3½h.p., 2-speed countershaft 29 gns.; Premier, 1914, 3½h.p., 3-speed coachbuilt combination, 35 gns.; Premier, 1915, 3½h.p., 3-speed, Canoelet sidecar, 45 gns. [5824

Quadrant.

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Quadrant, 1913, 3½h.p., 3-speed; 24 gns. [5826

Radco.

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Radco, 1915, 2½h.p., 2-stroke; 17 gns. [5829

Rex.

REX 3¼h.p., accumulator ignition; 75/-.—77, Acre Lane, S.W.2. [5925

REX, 3½h.p. Tourist, £12/10; 2-speed twin, £18/10; Rex 6h.p. twin, m.o.v., £14/10; 1913 2-speed, 6 h.p. Sidette, £36.—Motor Exchange, Horton St., Halifax. [5857

6h.p. Rex Motor Bicycle, with sidecar fittings, for sale, property of an officer, new condition; only genuine applicants need apply.—Roy, Angel Hotel, Worcester. [X4985

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Rex, 1915, 8h.p., T.T., clutch, handle start, 29 gns.; Rex 1914 8h.p. 2-speed combination, 27 gns. [5828

MOTOR CYCLES FOR SALE.

Rex.

REX 5-6h.p. Combination, 1914; £45; splendid condition.—Olive House, Thornbury Rd., Clapham Park, S.W.2. [5877

6h.p. Twin Rex, Bosch mag., spring forks, free engine, 2 speeds, m.o. valves, good tyres and belt, perfect order, splendid condition; £15, genuine bargain. —Box 2,011, c/o *The Motor Cycle.* [X5219

Rover.

ROVER Combination, 1918, run 400 miles, indistinguishable from new; £90.—Below.

ROVER Combination, 1917, in exceptional nice condition throughout; £70; both fully equipped, speedometers.—Below.

ROVER, 3½h.p., 3 speeds, solo, in nice condition; £34.—Percy and Co., 337, Euston Rd., London. [5940

3½h.p. Rover 3-speed Combination; £25.—De Paepe, Linden Braadshill, Colnbrook, Bucks. [5886

ROVER, 4h.p., 1914½, 3-speed, clutch, grand order; £28; must sell.—Box 2,012, c/o *The Motor Cycle.* [X5244

1914 3½h.p. T.T. Rover, just overhauled; £30.—Gourlay, Australian Hospital, Harefield, Middlesex. [5761

ROVER 1915 3½h.p. Combination, 3 speeds, genuine Rover sidecar, with brake, all accessories, excellent condition; £52.—Maudes', 100, Gt. Portland St., London, W.1. [5739

ROVER Motor Cycles, 3½h.p. and 5-6h.p. models, in stock for immediate delivery, both solo and sidecar outfits; trade supplied; no permits required.—P. J. Evans, 91, John Bright St., Birmingham. [5676

Royal Ruby.

ROYAL Ruby, 1917 (shop-soiled only), 3½h.p. J.A.P. engine, 3-speed Sturmey-Archer countershaft gear, kick start, hand clutch; list price £72; what offers, cash, or exchange good turnout, piano, or lightweight.—Bunting's Motor Exchange, Mason's Av., Harrow. [5867

Rudge.

RUDGE Multi, 5-6h.p., with coach sidecar, very powerful; £45.—Motor Exchange, Horton St., Halifax. [5856

RUDGE, 3½h.p., 1913, and sidecar, 2-speed N.S.U., in excellent condition; £22.—T., 24, Townley Rd., Dulwich. [5789

RUDGE Multi Combination, in real nice order and condition, speedometer, disc wheels; £35.—Percy and Co., 337, Euston Rd., London. [5944

RUDGE, 3½h.p., special model, all accessories, Jones speedometer, condition like new; £24.—Maudes', 100, Gt. Portland St., London, W.1. [5740

3½h.p. 1917 Rudge Multi, up-to-date machine, new condition, includes all accessories; price 50 gns.; guaranteed.—Wauchope's, 9, Shoe Lane, London. [5903

RUDGE Multi Coachbuilt Combination, 3½h.p., splendid condition; bargain; speedometer, mechanical horn; £29.—131, Green St., Forest Gate, E.7. [X5214

RUDGE Multi 1917 Coachbuilt Combination, in perfect condition, Jones speedometer, Stewart warning signal, lamps, new spare tyre and spares; £50 cash.—20, Amberley Grove, East Croydon. [5769

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Rudge Multi, 1914, 3½h.p., re-enamelled and replated, 36 gns.; Rudge Multi, 1913, 3½h.p., standard, 28 gns.; Rudge, 1913, 3½h.p., variable gear, solo, 23 gns., with sporting sidecar 29 gns.; Rudge, 1915, 5-6h.p., 3-speed, clutch, kick start, 37 gns.; Rudge, 1913, 3½h.p., single speed, 21 gns. [5827

Scott.

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Scott, 1914, 3h.p., 2-speed, clutch, kick start, Scott coach sidecar, 37 gns.; solo, 31 gns.; many Scott parts in stock. [5832

Sheffield Minor.

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Sheffield Minor, 1916, 2-stroke, sloping tank, as new; 19 gns. [5830

Singer.

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Singer, 1914, T.T., 2½h.p., clutch, 19 gns.; Singer, 1913, 3½h.p., clutch, 22 gns. [5831

3½h.p. Singer, all accessories, recently overhauled, enamelling and plate as new, Villiers hub, good tyres, thorough running order; open to inspection; cheap, £35.—W., 14, Barttelot Rd., Horsham. (D) [X5261

Sun.

SUN V.T.S., nearly new; £28, bargain; owner called up.—Roberts, 22, Woodland St., Smethwick. [5768

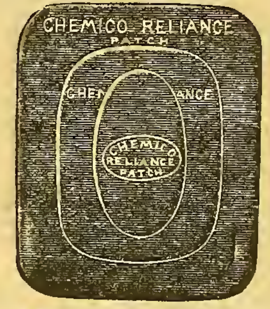
RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Sun-Villiers, 1916, 2½h.p., 2-speed, 24 gns.; ditto, single speed, 18 gns. [5833

SUN-VILLIERS 2-stroke Motor Cycle, nearly new Dunlop studded tyres and belt, mechanically sound; bargain, £12/10.—Peat, 72, The Chase, Clapham Common, S.W. [5778

Sunbeam.

1916 Sunbeam, 8h.p., condition absolutely as new, very little used; largest offer over £70.—Lubbock, High Elms, Orpington, Kent. [5783

"CHEMICO"



THAT PATCH

Means everything to you that the very best patch that can be produced can mean—with this difference—that whilst it might be easy to make a costlier patch

IT IS IMPOSSIBLE TO MAKE A BETTER ONE.

THE COUNTY CHEMICAL CO., LTD., BIRMINGHAM.

MOTOR CYCLES FOR SALE.

Sunbeam.

SUNBEAM 4h.p. Combination, 1917 War Office Model, fully equipped, run 700 miles; £105.—Percy and Co., 337, Euston Rd., London. [5941

3½h.p. Sunbeam Combination, 1914 model, nice sound turnout, includes Lucas best accessories, tools, storm apron; £75; guaranteed.—Wauchope's, 9, Shoe Lane, London. [5904

SUNBEAM Combination, 1916, 6h.p. M.A.G., lamps, horns, very good condition throughout; £100; exchanges entertained.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C.3. [0480

LATEST 1917 (May) 3½h.p. £90 Military Sunbeam, 3-speed, kick, Duplex tank, clutch, Lucas lamps, mechanical horn, unused 1918, beautiful machine; reasonable offer.—Lord, Mountfield, Prestwich. [X5246

T.D.C.

1916 T.D.C., De Luxe Motor Cycle, less magneto and carburetter; £8.—Mason's Garage, Letchworth. [5873

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—T.D.C., 1915, 2½h.p., 2-speed, 2-stroke; 22 gns. [5835

Triumph.

1913 Triumph, clutch model, excellent condition; £19, immense bargain.—54, Seymour Rd., Leyton. [5880

4h.p. 3-speed Countershaft Triumph, perfect; £45, or near.—Paterson, Percival Parade, Worcester Park. [5885

TRIUMPH, 1913, 3½h.p., clutch model, Bosch mag., Triumph carburetter, £22; Triumph, 1909, Bosch mag., £17; Triumph, 1913 clutch model, just been overhauled, requires reassembling, £20.—Maudes', 100, Gt. Portland St., London, W.1. [5741

RIDER TROWARD and Co., 31 and 40b, High St., Hampstead.—Triumph, 1913, 3½h.p., 3-speed combination, 36 gns.; Triumph, 1913, 3½h.p., 2-speed, 24 gns., with sidecar 29 gns.; Triumph, 1913 T.T., clutch, fine order, 25 gns.; Triumph, 1913 T.T., single speed, 22 gns.; Triumph, 1911, 3½h.p., 2-speed, clutch, 19 gns.; ditto, single speed, 14 gns.; many Triumph parts in stock.—'Phone: Hampstead 5392 [5834

Velocette.

VELOCETTE, 2 speeds, Watford speedometer, first-class order; £25.—Darke, Draper, Sutton, Surrey. [5759

Williamson.

WILLIAMSON 8-10h.p. 1914 Combination, water-cooled, perfect condition, very little used, every accessory; bargain, £60, or exchange 2¾h.p. Douglas and cash.—Gardner, Birchington, Kent. [X5252

MOTOR CYCLES FOR SALE

Wolf.

RIDER TROWARD and Co., 31 and 40b, H Hampstead.—Wolf, 1916, 2-stroke, good 19 gns.

WOLF, 2¾h.p., 2-speed, free engine, kick sta model; £27/10.—Motor Exchange, Hort Halifax.

Wooler.

RIDER TROWARD and Co., 31 and 40b, H Hampstead.—Wooler, 1916, 2-speed, 2-stroke, frame, as new; 29 gns.

Zenith.

ZENITH, 1917, 4-5h.p., Model C., lamps, ho done 1,000 miles; £52.—100, Gt. Portla London, W.1.

ZENITH Motor Cycle and Sidecar, 1913, Zenith-Gradua gear, B. and B., perfect con £45, or near offer.—Whitney, 48, Edith Rd., Pe

ZENITH-GRADUA, 3½h.p., just overhauled, a condition, new tyres and tubes, Stewart ometer, horn; £21, or nearest.—Gill, St. Elmo, W Essex.

3½h.p. Zenith-Gradua, 1912, J.A.P. engine, condition and perfect running order, had cally no use for last 3 years; 20 gns., lowest.—B Lowesmoor, Worcester.

RIDER TROWARD and Co., 31 and 40b, Hi Hampstead.—Zenith-Gradua, 1911, 3½h.p., 2 1913 6h.p., 29 gns.; 1913 6h.p. combinatio gns.; 1914 6h.p. combination, clutch and kick 45 gns.; 1914 8h.p. countershaft combination, 4 1915 8h.p. countershaft combination, 59 gns.; 8h.p. T.T. solo, 52 gns.; 1916 4-5h.p. twin, as 48 gns.; 1915 4-5h.p. twin, sporting sidecar, 5 solo, 44 gns.—'Phone: Hampstead 5392.

Miscellaneous.

1916 Indian Powerplus Combination, as new;

1916 Indian Powerplus Combination, as new; £8 both electric models.

1916 Enfield Combination, in good order; £

1915 Indian, 3-speed model, solo; £55.

1915 Harley-Davidson Combination; £60.

1915 Levis (Baby), disc wheels, like new; £

1914 Indian, 2-speed, and sidecar; £50.

1915 B.S.A. 4h.p. Combination; £50.

1913 3½h.p. Rudge Multi; £28.

1913 2¾h.p. Douglas, 2-speed; £33.

1914 6h.p. Sunbeam Combination, A1 condition;

1914 New Hudson Combination; £37.

1913 New Hudson and sidecar; £32.

1913 Rover, 3-speed, solo; £33.

1913 Arno, 3-speed, and sidecar; £24.

1913 6h.p. Rex and coach sidecar; £45.

1912 6h.p. Rex, solo; £20.

3½h.p. Brown, 2-speed N.S.U.; £19/10.

1912 Douglas, 2-speed, in splendid order, newly en elled; £25.

ALL the Above Machines are guaranteed in the of order, and sent on approval, deposit.

TO Officers and Soldiers on Leave.—Please note we do not let on hire motor cycles, but we prepared to sell you a machine and repurchase same a given fixed price when your leave is up, provi that the machine is in good running order.—Jones' age, Broadway, Muswell Hill, N.10. 'Phone: Hor 2562. [5

MEBES and Mebes have the following motor c for immediate disposal at bargain prices:

1916 Enfield 6h.p. Combination, as new; £85.

1917 4¼h.p. B.S.A. Combination, as new; £90.

1914 2¾h.p. A.J.S., 3-speed countershaft; £40.

1914 2¾h.p. Enfield, 2-speed, chain drive; £35.

1916 2¾h.p. Connaught, 2-stroke; £26.

1916 Levis, free engine, clutch; £27/10.

British Magnetos.

IT is hardly necessary for us to remind our readers that we have in the past done our utmost, in conjunction with our parent journal *The Autocar*, to further the interests of the magneto industry in this country. The present is, however, an appropriate time for referring again to this important subject, and for this reason. Last week the British Ignition Apparatus Association invited representatives of the press and the motor industry to visit the works of certain firms who are members of the Association. The object of this gathering and inspection was to convince those who were intimately concerned in the commercial use of magnetos and those whose position enabled them to pass on their knowledge to the public, of the absolutely sound condition of the British magneto industry. Personally, we required no convincing, for we had been on a somewhat similar round of inspection a few months ago; but, though we had learnt much on that occasion, our second visit last week showed us that the whole subject could not be assimilated at once, and we became acquainted with many more details of this important work.

At the outbreak of war there was, we believe, only one British firm engaged in the manufacture of what will readily be acknowledged to be a highly specialised job, viz., the making of magnetos, and these were not being made for motor cycles or cars, and much less for aeroplanes, but for work of a far less exacting character. That being the case, the strides made by the British magneto manufacturers are little short of miraculous, and they have deserved the gratitude of the whole nation.

Before the war it was—and this in spite of our efforts—generally accepted that the Germans were supreme and unapproachable in the manufacture of magnetos. In fact, one journal went so far as to assert that there was something in the air of Stuttgart which, like the water of Burton in the matter of beer, lent itself to the making of magnetos; further, that there was some wonderful quality in the mentality of the German workman which tended to the same end, and that it was therefore useless to try to compete with the great enemy firm that flooded our country with magnetos—and good magnetos, too, else would our fault have been far greater.

Now, to the infinite credit of all concerned, we have proved to the world that what the Germans can do, we also can do, and do it better. For, in spite of the immense difficulties which had to be faced in obtaining the correct raw materials, in setting up suitable machinery, and training workmen to the high degree of skill that is necessary, the British magneto is probably the best in the world, and certainly second to none. We are afraid that the Government did but little to assist. First of all, they ignored the Britisher, and expected to get all the magnetos they required from America. Then they changed their minds, and pressed for the immediate delivery of large quantities of magnetos "to a design not yet completed and on plant we had not got." We quote from memory the witty remark of the chairman, Mr. Peter F. Bennett, at one of the gatherings which formed a pleasant change from the round of inspection and the noise of machinery.

On aeroplanes magnetos are put to very strenuous work. With some engines the vibration is enormous, and when there are a large number of cylinders, even though the r.p.m. is not excessive (say, twelve cylinders at 1,500 r.p.m.), the magneto has to produce 9,000 sparks per minute. We saw an aeroplane magneto of special design giving four sparks per revolution which is capable of a regular output of 16,000 sparks per minute. This, of course, means very careful design and the utmost accuracy in manufacture. One of the latest Bosch magnetos, recently captured from the enemy, broke down at about one-third of this speed. Is it therefore any wonder that even the German airmen use British magnetos—when they can get them?

An index to the advertisements in this issue will be found on the page facing the back cover

NOVEL TWO-STROKE DESIGNS.

Some Recent Patents granted to Inventors of "Improved" Two-stroke Engines.

ONE has only to go through the patent files to appreciate that the interest in the two-stroke cycle shows no sign of abating. At a recent meeting of a graduates' section of the Institution of Automobile Engineers, we were interested to learn that Mr. Cyril G. Pullin, the last Senior T.T. winner, was actively interested in the two-stroke engine, and he gave some very interesting figures to show that he has been thoroughly investigating the merits of the simple engine with a view to its embodiment in a low price motor cycle for after-the-war production.

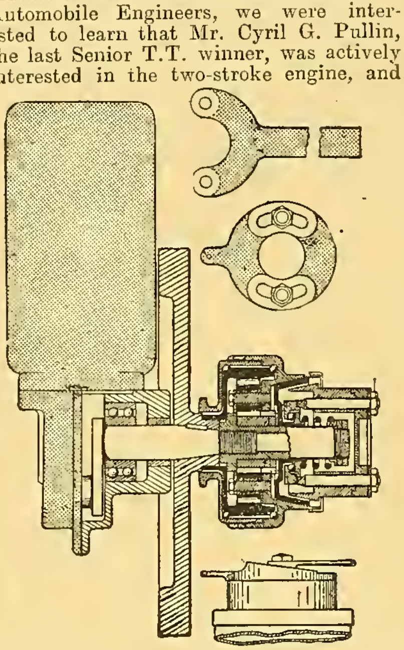

Fig. 1.—A patent by Mr. Cyril G. Pullin of a simple epicyclic gear to be fixed on the crankshaft.

Mr. Pullin gave a brief specification of a machine which, in the motor cycle world, would occupy the same position as that enjoyed by the Ford among cars. Hence the patent drawing bearing his name, which we reproduce (fig. 1), while not referring to two-stroke engines exactly, may be taken as a shadow of coming events.

The design is of a simple epicyclic gear for the crankshaft of what appears to be a small water-cooled two-stroke engine. The invention consists in a spring-controlled clutch with internal and external friction surfaces reciprocating between corresponding rotary and stationary members, a non-rotating device withdrawing the clutch from engagement, and a rotary action member having inclines actuating the clutch withdrawing device.

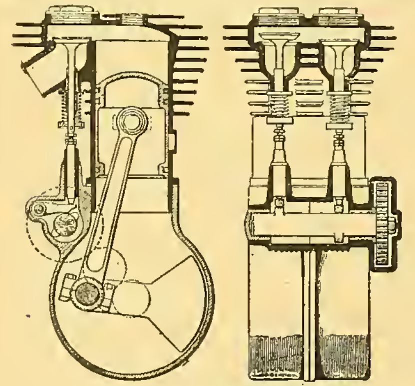

Fig. 2.—A two-stroke patented by Mr. G. E. Stanley.

Another well-known name in the competition world is G. E. Stanley. The ex-Singer crack has patented a two-stroke engine (fig. 2), which is interesting. In a single-cylinder engine, the invention consists in the embodiment of two exhaust valves of the poppet type, which are operated by cams on a half-time shaft. These cams are placed at 180°, so that the valves are actuated alternately. Each valve, therefore, is subjected only to the effects of one-half the exhaust strokes, and has an opportunity of cooling between each operative period.

Another interesting design is shown in fig. 3, which, while being very unconventional, is, nevertheless, interesting to all who follow the mechanics of the motor cycle. This is Marshall's motor wheel—an attempt to embody the power plant within the hub of the wheel. In fact, the cylinder (water and air-cooled) acts as the hub shell in which a ring piston operates. It has two connecting rods and two crankshafts which drive bevel pinions meshing with a larger and fixed toothed ring. A study of the drawing will reveal that the engine must revolve about the central axle, since the toothed ring is fixed. The carburetter is fixed to the hollow spindle, and the ignition current is carried through a fixed ring shown at the left side of the drawing.

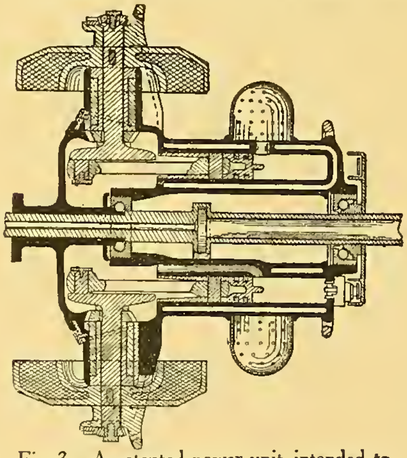

Fig. 3.—A patented power unit intended to be used within the hub of a wheel.

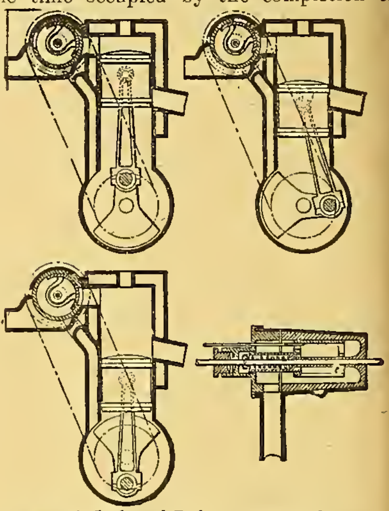
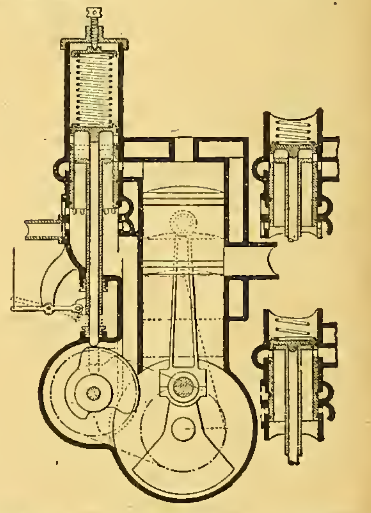
Probably the most interesting designs in the group under review are those of Messrs. Thomas and Edwards. These designs embody a rotary and a cam-operated piston valve respectively.

Figs. 4, 5, 6, and 7 depict the rotary valve design. The valve is located at the side of the head of the cylinder, and is driven by a chain or other suitable transmission. It is intended that a charge of gas is, during the up stroke of the piston, drawn into the crank case through a transfer pipe leading from the valve. On the approach to the completion of the upward stroke of the piston the supply of gas is cut off by the valve, and air from the atmosphere is admitted during the time occupied by the completion of the stroke. This air being the last to enter the transfer pipe will be the first to enter the cylinder when the new charge follows the exhaust down the cylinder at the bottom of the next stroke; therefore there is a layer of air between the burnt and new gases. Within the rotary valve there is a cut-off valve which can be hand operated.



Figs. 4, 5, 6, and 7 show a patented rotary valve, which is located at the side of the head of the cylinder.

In the second design, figs. 8, 9, and 10, the same principles are embodied in an engine having a piston valve, within which is a cut-off valve. This piston valve is operated by a cam, with a spring for its return.



Figs. 8, 9, and 10.—A design having a piston valve operated by a cam.

OCCASIONAL COMMENTS.

By "IXION."

The Future of the Little 'Uns.

I NOTICE that various readers are bad-wording me in our Correspondence columns for espousing the cause of the lightweight, and prophesying that some day small engines will reach a standard of speed and reliability now attained by nothing under 3½ h.p. Please perceive that I have never said that pre-war lightweights or the few existing experimental lightweights will do the trick. Technically, there is no reason why we should not get all the power we need out of a miniature single-cylinder, two-stroke or four-stroke; practically at least seven buyers out of ten would give a decent lightweight the preference over a decent medium or heavyweight.

In Favour of Lightweights.

READERS will denounce such a chronic speedster as myself for estimating the potential lightweight enthusiasts at 70% of the motor cycling public; but I guess the percentage with some confidence. Practically all the girls (bless 'em!) prefer lightweights. So do the old men. So do the lazy men, who dislike propping up solo machines in an attitude reminiscent of helping your mother-in-law into a tram. So do the nervous men (and many motor cyclists are secretly terrified of their machines three times per day, though they would rather die than tell you so). Deducting the stalwarts, you get a large majority for the lightweight, when—the lightweight is fit to ride.

Wanted, a Lightweight de Luxe.

HITHERTO the motor world has been dominated by the fallacy that the price of a motor should be in proportion to its bulk. This certainly applies to ships, buns, and certain other commodities, but not necessarily to motor bicycles. It has been taken for granted that if a 3½ h.p. bicycle costs £60, a 1¾ h.p. bicycle should sell at £30. This is largely a delusion. When you are toting round a lot of h.p. which you seldom use, you can put up with indifferent workmanship and third-rate design and material, up to certain limits: when your nominal h.p. is the absolute minimum requisite for road work, you need a machine de luxe. The manufacturer can save very little on the cost of material in making a 1¾ h.p. as compared with a 3½ h.p. Workmanship is the main item in both costings, and the workmanship of the little 'un must be superb: otherwise, as every experienced rider of the breed knows, oil leaks and rapidly fading power make the machine a curse to its owner. I quite think that the best way to accelerate the inevitable and natural lightweight boom would be for a firm of the highest standing to produce a 1¾ h.p. at £50 or £60. If this attempt be made, the resultant machine will not ooze oil at every pore, will not drop to two flea-power after a week's work, will not toil painfully up gentle grades at 5 m.p.h., but will create a vogue for itself amongst a moneyed and fastidious class of buyers. Then some vulgarer soul will plot to market a similar machine at a lower cost, urged on by the coming millions of girl motor cyclists and others. And the decent lightweight will become a commonplace.

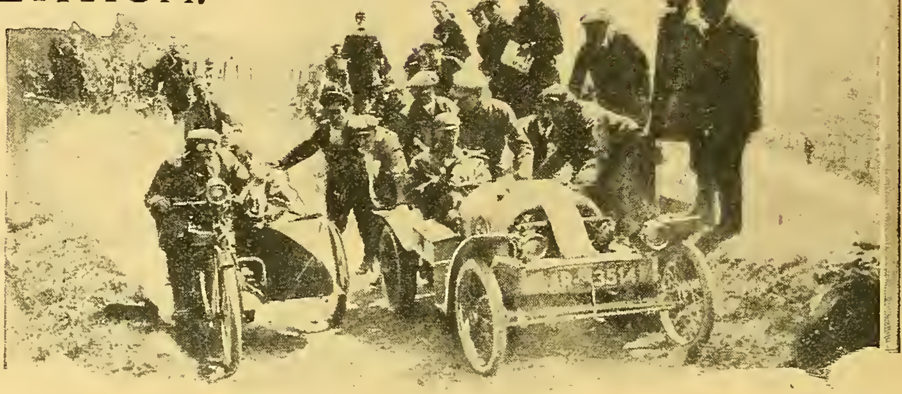
The Technical Possibilities.

"VIC," who regards my lightweight dreams as entirely pernicious, is perhaps unaware that the smallest petrol engine cylinders in the world are made for continuous heavy duty under war conditions. Price being immaterial within wide limits, the engine in question stands up well. To get the requisite power out of a stated c.c. is a matter of development, and development always awaits a stimulus. We did not get 300 h.p. out of a 150 h.p. engine until war aviation compelled such developments. We did not get 70 b.h.p. out of a four-cylinder 80 mm. bore car engine until a quaint taxation scheme and trade competition set engineers' brains waving feebly in that direction. Nor shall we get roadworthy lightweights till the necessary stimulus is applied; and then everybody will wonder why we did not have them in 1906. Maintenance of power in lightweights depends on three main factors: The lubrication system must be proof against swift carbonisation (past lightweights have been disfigured by a ridiculous oiling system: barely tolerable on light-duty engines, but insane on machines forced to rev. continuously). The various metals employed, especially for valves and piston rings, must be well chosen; no profound problem in metallurgy is involved, but in the past our lightweight valves warped and pitted, our lightweight piston rings ceased to act as a compression seal in three days' work, our pistons distorted, and our cylinders swelled egg-shaped. Cooling must be efficient: and pre-war air-cooling was barely adequate for engines of 3½-7 nominal h.p., which did nearly all their work on quarter throttle or less; still less was it efficient on the babies, which normally ran on half throttle.

The Commercial Aspects.

AS hinted above, the business factors are our chief handicap. For the present, the lightweight engine must be beautifully made. It will show a very trifling saving over the bigger engines on the score of raw material, but there will be a much bigger percentage of scrap in the shops, the workmanship must be more highly skilled, and the materials must be of better quality. To express this point graphically, I should say that a crack firm could make a first-class 1¾ h.p. with profit at a selling price of £70. a ditto 2¾ h.p. at £60, and a ditto 3½ h.p. at £50. In actual practice the public expect a 3½ h.p. for £50 and a 1¾ h.p. for £25. This is the real reason why the half-baked two-stroke leapt into such sudden popularity. Every engineer was familiar with its intrinsic limitations and its unsolved problems. But in its cruder forms it was an infinitely cheap engine to make, and, however shoddily it might be slung together, it would run after a fashion, and maintain such power as it could squeeze out for a thousand miles. It was the path of least resistance: and the trade took it. When its surviving weaknesses yield to invention, it may solve all the lightweight difficulties: and it so happens that two-strokes are receiving unusual attention from clever men just now.

THE SINGLE-CYLINDER IN COMPETITION.



A 3½ h.p. Premier sidecar passing an H. and S. cycle car on Amulree Hill.

An Harangue on the Merits of the Single, as Proved by Competition Results.

By DEAN BARRY.

GENTLEMEN of the trade, gentlemen of the road, I hold a brief for the single-cylinder engine. It is my honour to address you to uphold the type of engine that has done so much to make motor cycling popular. There are many among you who would forget the tried and proved friend of the past and follow the flame of a will-o'-th'-wisp because there is so much written and said and promised by the enthusiasts for "flat twins" and "big twins" and "fours."

I am a "big twin" man myself. I like the idea of a good "four" also, and I have owned a "flat twin"; but I have not secured extra pleasure equivalent to the extra cost and trouble with a big twin compared with the simple reliable single. True, with a big twin sidecar I have taken a few minutes off my best single sidecar time on a thirty-mile journey I made fairly frequently, and I have made some very long runs with a sidecar without changing gear, but it has cost me at least another £20 per annum to do it, and I doubt whether I got value.

I think of four cylinders because I am getting old—at least I am older than I was—and the luxurious appeals to a man who is an enthusiast.

"Flat" Twins.

As for flat twins, perhaps my experience has been unfortunate; but for ordinary every-day sidecar work, and an occasional tour at holiday times, for the man of moderate means I favour the medium powered single. We are not all worshippers at the shrine of mechanical ingenuity. It is trite to say that most of us own a motor cycle to use as a means of transportation, to get out into the country. In other words, it is motor cycling that appeals to us, and not the machine as an example of the skill of the motor cycle engineer. What does it matter if the flat twin is theoretically superior? The fact remains, the single will do the same amount of work at a lower cost and at less expenditure of time in tuning than any other type of engine. As for speed—well, we can double the legal limit when we want to, and, what is more, the modern single can maintain that speed, if need be, as witness the twin-single test, over which there was so much controversy. The very fact that it was difficult to decide to which machine the more credit was due—when the twin had an engine nearly twice the capacity of the single—speaks volumes.

Pre-war competitions — as strenuous as they were—failed to eliminate completely the medium powered single. They seem so long ago that they may be forgotten by many of the present-day riders and potential riders.

The Z bend on Cowdale, one of the noted hills in the A.C.U. One Day and Six Days Trials of 1914

The Single in Competition.

Great injustice was done to the single-cylinder by competitions committees, who forced the smaller type of machine with sidecar to compete on level terms with big twins. Competition rules were framed to eliminate as many machines as possible—to do this, courses had to be found which would knock out the "big feller," and they did it. What chance had the 500 c.c. single sidecar outfit over courses picked to try so severely machines with engines twice the size? Yet they acquitted themselves very creditably.

(1) One of the many paved lanes in Yorkshire included in the 1914 A.C.U. Six Days Trial.

(2) A hairpin bend on the famous Tornapress Hill (better known as Applecross), which rises over 2,000 feet in six miles of grass grown, boulder-strewn track.

(3) A "staircase" lane in the A.C.U. Six Days Trial.

I was in most of the 1914 trials as passenger aboard a single-cylinder outfit, and only those in these competitions and on similar machines know the real capabilities of the single. Take, for example, the A.C.U. One Day Spring Trial of 1914. There were fifty-four single solo mounts entered, of which thirteen obtained first-class certificates and twenty-seven certificates of merit; only four failed to finish. The twin solo machines did better, it is true: but most of them were big twins, and there should be no course where sidecars can go at all that should knock out a big twin ridden solo.

In the sidecar class, thirteen singles started, of which seven finished—one with a first-class certificate and a 500 c.c. machine at that. The remaining six secured certificates of merit. The twin sidecars did not do so well. Forty-six started, twelve secured first-class certificates and eighteen certificates of merit—thirty all told.

Then in the A.C.U. Six Days', fifty-six solo singles started—many of them ridiculously small lightweights, some under 200 c.c. capacity—yet thirty-four finished, while in the twin class thirty-two solo machines started and only seventeen finished. A few manufacturers were daring enough to enter 500 c.c. single-cylinder sidecars in this event. There were five of them, and two finished, one—again a 500 c.c. outfit—being awarded a special medal for its meritorious performance. In the twin classes, thirty-two solo machines started and seventeen finished; twenty-four sidecars started and thirteen finished.

In this event the singles proved that they could do all the twin could accomplish—perhaps not so well; but it is sufficient to know that over the most difficult courses ever picked for a trial—up staircase lanes and almost every freak hill to be found in hilly Yorkshire and Derbyshire—the singles stood up to the hardest six days' gruelling ever planned by the A.C.U.

Again, in the Scottish trials of 1914 solo singles secured forty-one awards out of fifty-two entries, solo twins nineteen out of twenty-seven, and sidecar twins ten out of twenty-one. There were three single sidecars in this time, and for the first four days they covered themselves with glory on the noted hills of Scotland, including Amulree, Abriachan, Cairn-o'-Mount, Cockbrig Ladder, and Trinafour. It was the famous Applecross Hill, with its 2,200 feet climb in six miles of boulder-strewn path, that proved their Waterloo. They all finished with red-hot engines, after about four miles in bottom gear.

But Applecross has been scaled in competition by a single-cylinder sidecar. Hugh Gibson in the 1913 Scottish trial succeeded in making a non-stop climb—

The Single-cylinder in Competition.—

in fact, he secured a gold medal—with a 3½ h.p. Bradbury fitted with a three-speed hub gear. On the same or a similar machine the same rider secured an award in the 1912 event, in which, out of twenty-nine gold medals, nineteen were secured by singles.

Has ever a 500 c.c. twin sidecar outfit won an award in any of these classic events? No. It is safe to say that a twin of even 600 c.c. capacity cannot emulate the 500 c.c. single.

T.T. Evidence.

Then there is the T.T. race. The winners of both senior and junior events in 1914 were singles—a Rudge and A.J.S. respectively. In the junior event fifteen singles started and eleven finished. The twins numbered thirty-four, but only nineteen finished.

In the senior event, forty-nine singles started and thirty-two finished; fifty-two twins started and only eighteen finished.

Finally, let us remember that all the 500 c.c. records are held by the single-cylinder machine. Twins have wrested the laurels from the single-lunger, but the single has resecured them. The Norton alone holds the following:

500 c.c. CLASS. SOLO RECORDS.

	Speed.
Flying kilo.	82.85 m.p.h.
Flying mile	78.95 m.p.h.
Flying five miles	75.88 m.p.h.
Standing ten miles	73.29 m.p.h.

750 c.c. CLASS. SOLO RECORDS, WITH 500 c.c. ENGINE.

	Time.
Kilo.	0m. 27⅕s.
Mile	0m. 45⅘s.
Five miles	3m. 51⅕s.
Ten miles	8m. 11⅕s.

500 c.c. SIDECAR RECORDS.

	Speed.
Flying kilo.	64.65 m.p.h.
Flying mile	62.07 m.p.h.
Flying five miles	58.78 m.p.h.

All the 750 c.c. sidecar records are held by a single, as well as the five miles record in the 1,000 c.c. class.

What has the twin done to warrant the opinion so popular among "experts," that the single is doomed? There is a lot of life in the old single yet, and now that really efficient shock absorbers are within a measurable distance of success, it will be a long time before the single will be a back number and classed among the obsolete steps in the evolution of the motor cycle. Gentlemen, what is your verdict?

LIVING IN THE COUNTRY.

The Motor Cycle and the Town Dweller.

FOR many years past the average British artisan has resented, silently or otherwise, the evil fate which compelled him to live in dingy streets. He intends to alter this after the war. Many thousands of soldiers have applied for "homesteads" (presumably a country cottage with a bit of land attached to it) after the war. Thousands of civilians are putting in all their spare time on allotments, which more often than not consist of a bit of shallow, third-rate land, practically unfenced, and most inconveniently situated in relation to their homes: one may see these patriots wheeling gardening tools along public streets in children's pushcarts any Saturday afternoon. Some of these allotment-holders will relapse after the war. Many are bitten with the land craze. They have conceived a novel passion for a country cottage with a few rods of land attached to it inside their own fence. After the war there will be a great push for country homes for artisans: and transport will be a main difficulty. Garden cities are perpetually being founded in the suburbs of London and of a few large provincial towns. In such cases transport difficulties do not exist. The motor 'bus and electric tram services push out their tentacles a mile or two further, and the problem is solved. This solution is hardly applicable to typical provincial areas. Still less is it desirable. England would be spoilt if our urban tram services defaced and endangered our country roads.

Nevertheless, a country home is necessarily distant from the factory where millions of intending rural householders will work. A Labour Government is a possibility of the near-future, and may be trusted to remember the workers' aspiration for pleasanter homes. Whilst it cannot be pretended that the motor cycle can solve all the transport questions involved, it is tolerably obvious that the artisan will enter more and more into the market for the cheaper types of motor, with the motor bicycle first, and the cycle car second. In framing post-war plans, manufacturers should allow for this novel and expanding market. It implies the placing of a new value on two familiar items concerned in every production scheme. The first is that of output, the second is that of price. In the first place, the artisan market is largely untapped by motor cycles, except amongst the best paid workmen, especially in Lancashire, Yorkshire, and Birmingham. Much larger sales can be expected in this direction. Secondly, the lower the price, the greater the market. The sporting youngster and middle-class hobbyseeker are not particular to £25 what they pay for a machine. Many artisans would buy at £50, but cannot buy at £75. If any firm can weigh in with a cheap quantity 3½ h.p. machine, capable of sidecar work, within three years after the end of the war, it will do a mighty business.

Despatch riders attached to the Royal Engineers mounted on W.D. Triumphs. Reading from left to right: L. Moore, H. Rayne, H. Newton, and H. Dovaston. All were enthusiastic motor cyclists before the war. Moore was a track cyclist; Rayne, Newton, and Dovaston being keen members of various motor cycling clubs.

It's just like this

—there cannot be too many CLYNOS when the War is over—its popularity before, its record during the War, make that a certainty—
THEREFORE, we have decided on a policy embodying the following features:

1. **Mass production of one model (to increase output and reduce productive cost).**
2. **Prices for both Outfit and Spares competitive with any combination of equal reputation.**
3. **Rotational delivery (to ensure to those who order now, delivery within a specified period of the ending of the War).**

That's a policy you will appreciate—so ask your agent for fuller details and us for latest folder, "The Post-war Clyno."

SUMMER TIME.

June 20th	9.45 p.m.
,, 22nd	9.49 ,,
,, 24th	9.49 ,,
,, 26th	9.49 ,,

British Engineering Standards Association.

The Engineering Standards Committee has now become incorporated under the Companies Acts, 1908-1917, the word limited being omitted by licence of the Board of Trade.

Scotch Shale Oil.

The companies interested in the production and distribution of this useful commodity have now entered into an arrangement to facilitate its distribution. Whether the arrangement will bear any practical fruit at the present time or not we cannot say.

Oil from Slate?

Quoting a Swedish contemporary *The Autocar* states that satisfactory experiments have been carried out in Sweden with this end in view. And yet there are still people who persist in regarding themselves as intelligent and who find time to ridicule the old alchemists!

Westerham Motoring Popular.

Twelve L.G.O. 'buses were running on a recent fine Sunday between Bromley and Westerham Hill, distance eight miles, and every day these 'buses carry a number of pleasure riders, as they link up with the service from London, Woolwich, etc., the return fare from the city being 2s. One notes many changes on the Westerham Road, but most of the wayside tea and refreshment houses are carrying on their business as usual, thanks to the 'bus tourists alone.

Petrol in Ireland.

In the House of Lords last week, Lord Willoughby de Broke asked the Government whether the Defence of the Realm Regulations have been applied impartially as between Great Britain and Ireland. He said with regard to petrol, unless one happened to be a Sinn Feiner it was difficult to get any petrol at all; if one belonged to the disloyal forces petrol was immediately forthcoming. These things seemed to show that Ireland had been placed in a particularly privileged position.

The Earl of Crawford, in reply, said that the restrictions on the use of petrol applied equally in Great Britain and Ireland, and were administered by the police.

Special Features.

THE FLAT TWIN TWO-STROKE.

THE SINGLE-CYLINDER IN COMPETITION.

NOVEL TWO-STROKE DESIGNS.

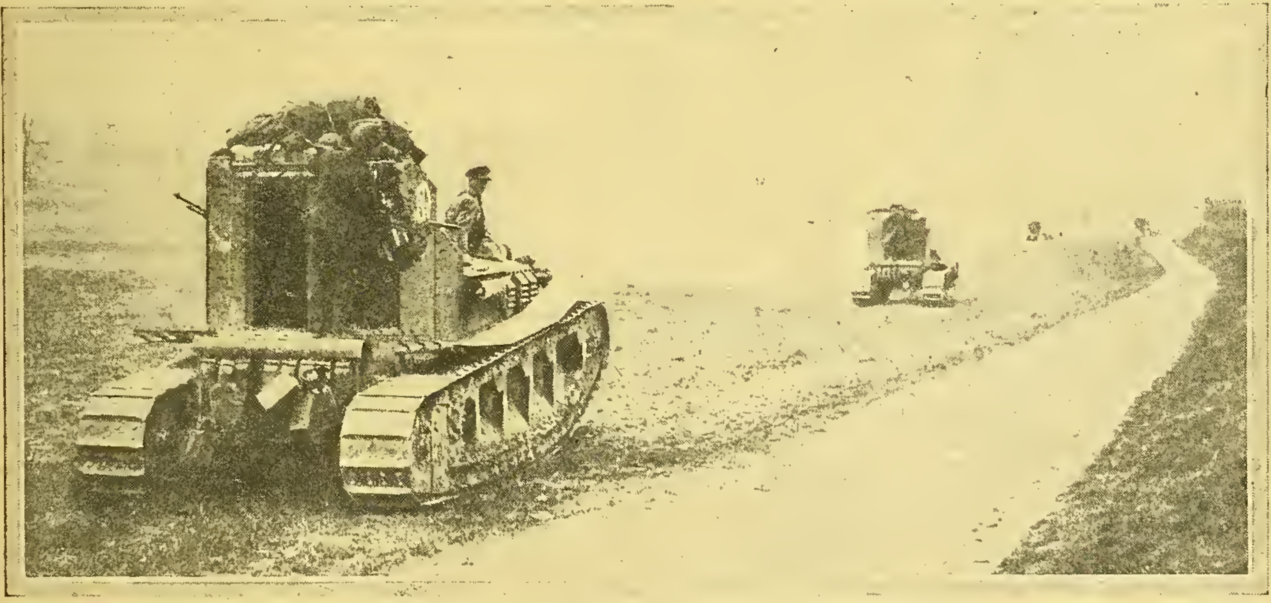
The £190 Sidecar Outfit.

From the *Johannesburg Sporting Star*, April 20th, 1918: "If anyone had said three years ago that, in 1918, a sidecar outfit would fetch £190 he would have been laughed at. Yet that is the price of the war model Collier's Matchless machine. The Diamond Cycle Co. have sold both the machines they had. They certainly were wonderful models, beautiful in detail and finish."

"Endurance" Run in U.S.A.

The Crotona Club recently held an "Endurance" run—apparently a euphemism for a road race—from New York to Boston and back. The distance was 530 miles, and had to be covered in the day, but out of seventy-four starters eighteen made perfect scores.

The most prominent makes were the Indian and Harley-Davidson, which divided between them the chief prizes, of which there appears to have been quite a plethora. H. Kunath (Indian and sidecar) made the best all-round showing.



Tanks of new design have been employed on the British Western Front. They are much lighter in weight and much faster than the old type. They do not replace the tanks of recognised form, however, but are intended to be used in positions where mobility is a great consideration.

Further Dunlop Activities.

The Dunlop Rubber Co., Ltd., is now developing an interesting endowment fund or insurance scheme for the benefit of its male employees. The main point of the scheme is that on attaining the age of fifty-five an employee shall be in a position to draw upon a substantial nest egg provided by the fund. The scheme embraces provision for pensions, death, and sickness.

Employment for Young Men.

Those interested in the careers of young men are recommended to get into touch with the Staff Bureau (Permanent Service), Dunlop Rubber Co., Ltd., Aston Cross, Birmingham. Ex-army men are specially looked for.

The Preservation of Pneumatic Tyres.

According to the Hun motor paper, *Motorwagen*, pneumatic tyres are best kept in a cool and well aired cellar. This most of our readers know, but experiments carried out in Germany indicate that inner tubes keep their elasticity better when in a solution of 10% glycerine and 1% soda in water.

The Dye Trade.

We have more than once dealt with the importance of the dye trade to the motorist as a possible source of—or, rather, inducement for—home-produced fuel of the benzene series. To develop the trade after the war, the Government has decided to prohibit the importation of any foreign dyes—which means German, as no other country counts for much—for a period of ten years after the war, "except under licence."

Trade Reconstruction in Germany.

While we are beset on every hand with committees for the amelioration of our post-war this or our post-war the other it is interesting to note that Germany is apparently little better off. In fact, a writer in the *Norddeutsche Allgemeine Zeitung* says that Germany is suffering in this war for her sins of omission, and his suggested remedy is the establishment of Chambers of Commerce in neutral countries at once, and in other countries after the war.

Apparently the suggestion meets with official approval and the guidance of official committees.

A Post-war Four-cylinder Engine.

A few days ago we dropped across Mr. A. W. Wall, the inventor of the Wall Auto-wheel. Mr. Wall has no active connection with the syndicate who make the attachment which bears his name, and is now engaged in work of a totally different nature. Incidentally, Mr. Wall informed us that he has designed a four-cylinder engine for motor cycles for after-the-war production. Details of this engine, of course, cannot be published, but we can say that presswork parts enter largely into its construction, and by reason of the cheapness of production of such parts the cost of making a four-cylinder engine for motor cycles should be considerably reduced. The four-cylinder engine is receiving a considerable amount of attention at the present time, and there will probably be several promising makes on the early post-war market

Mentioned for Valuable Services.

In a list published on June 14th of "Mentions for valuable services in connection with the war" brought to the attention of the Secretary of State, we notice the name of Lt. (Temp. Capt.) Cyril Patteson, R.A.F.; and among those employed by the Air Ministry the name of W. F. Guiver (Rolls-Royce Co.) is one of those brought to the notice of the Secretary of State in respect of the valuable services they have rendered. Both Cyril Patteson and W. F. Guiver have many brilliant performances to their credit in motor cycle competitions held before the war.

?

Have you Given
a
DEFINITE ORDER
for
The Motor Cycle
to be
Reserved or delivered regularly in future?

After JUNE 24 Newspaper "Returns" will be prohibited by the Government, and Newsagents will no longer be able to supply chance buyers. Only those readers who give definite orders will be sure of getting their copies.

An official Order—which comes into force on June 24th—has been issued by the Controller of Paper, prohibiting the system of supplying newspapers and periodicals "on sale or return."

In the past it has been the custom with publishers to allow newsagents to return unsold copies, and this enabled them to provide for the requirements of travellers and other chance buyers.

The new Order prohibits this custom, and consequently the newsagents, being unable to return unsold copies, obviously cannot be expected to run the risk of having copies left on their hands, and in future they will take only sufficient to supply definite orders.

To avoid the disappointment of being unable to obtain "The Motor Cycle," each reader who has not yet given a standing order should at once ask his newsagent to reserve or deliver a copy weekly, or, if preferred, a direct subscription may be placed with the publishers.

ILIFFE & SONS LTD.

Bosch Magnetos in Australia.

A recent Australian order forbids the importation of any magneto bearing the trade mark "Bosch."

Another Birthday Honour.

Capt. Geoffrey de Havilland, aeroplane designer (also designer of the Blackburne motor cycle formerly known as the de Havilland), has been made an Officer of the Order of the British Empire.

Typographical Error.

In the article by "Vedette" on "The Side-by-side Twin Engine" in our issue of June 6th the following sentence occurred with reference to the vertical two-cylinder engine with 180° cranks: "Its only drawback is its very irregular firing torque, two explosions taking place during one revolution and one in the next." The second "one" should, of course, have read "none."

A Quickly-built Motor Bicycle.

At a machine repair unit somewhere in France the captain-in-charge asked for a Harley-Davidson and sidecar. He was told that no such machine was available. The captain then pointed out that there were plenty of mechanics and plenty of parts, so he desired one to be built with the parts available. In two days two lieutenants and six motor cycle repairers built up a complete Harley-Davidson and sidecar from the spare parts, which gave absolute satisfaction, and six weeks after being built it was reported as going "better than ever."

Hun Fuel Experiments.

The shortage of petrol in Germany has been far worse than it has in England, and at times the fuel position in that country has been absolutely desperate. This has led to the carrying out of a number of interesting experiments with motor fuels, which have brought forth interesting results.

It was found that a litre of pure petrol could be run a distance of 5.8 km., pure benzole 7.1 km., one part benzole and one part alcohol 7.5 km., one part benzole and two parts alcohol 7.2 km., one part benzole and three parts alcohol 7 km., one part benzole and four parts alcohol 6.6 km., one part benzole and five parts alcohol 6 km., pure alcohol 5.4 km. It is clear, then, that the mixture producing the best results is one part benzole and one part alcohol.

The Norton Post-war Policy.

Mr. J. L. Norton has in hand drawings of a four-wheeled passenger runabout on motor cycle lines, utilising the Norton Big Four as a power unit; also alternative designs for rear springing of the Norton motor bicycle. These designs have not progressed beyond the drawing office, and are merely referred to here to show that the firm do not intend to allow the grass to grow under their feet as soon as they are able to turn their attention to experimental work.

With regard to the firm's post-war production, it has been practically decided to confine their efforts to two types—the Big Four, built with a high clearance for all weathers and purposes, and with enclosed all-chain transmission; and a purely sports model, with single gear ratio or with Philipson pulley.

THE MOTOR CYCLE AVIATION SECTION

EARLY REMINISCENCES. A TEN-MILE TAXI. AIRWOMEN.

On the Grand Scale.

One correspondent recently reported that there were three hundred Allied machines in the air simultaneously on one short sector of front during the April fighting.

◆

New Honours.

The King on his birthday instituted the following new flying decorations: The Distinguished Flying Cross, the Air Force Cross, Distinguished Flying Medal, and the Air Force Medal. Since the New Year Honours were published, 22,600 decorations have been conferred on officers and men in France and Flanders.

◆

Ply-wood on Hun Machines.

Visiting the Agricultural Hall the other day, we noticed that the leading edge of several German planes is kept true to contour and prevented from sagging by ply-wood extending as far back as the main spar, both above and beneath. The spars of the Fokker triplane wings are built up largely of ply-wood by a box method of construction, which is much lighter than solid ash.

◆

Marcel Hutin's Son Wounded.

The name of M. Marcel Hutin is well known throughout the British Empire as being that of one of the most brilliant French journalists and war commentators.

We note that his son, Roger Hutin, was very severely wounded on May 31st while engaged in bombing the German lines, just after he had destroyed an enemy machine. In spite of the seriousness of his wounds, Cpl. Hutin was able to bring his machine back to French territory. For this act of bravery he has received the Military Medal and the Croix de Guerre.

◆

The First Flying Meeting.

The official programme of the first flying meeting held in England is amusing reading in these days. Many will remember the fiasco at Doncaster in 1909, and recollect the weary wait to see the planes try to overcome the force of gravity. In those days the experimental machines clung lovingly to mother earth—too tenaciously at Doncaster during that memorable October week.

The code of signals was amusing, among them being signs denoting "the machine which is going to start is making a trial trip," "machine partly broken, tester not hurt," "a breakdown to motor prevents starting," "120 feet altitude reached," and so on.

The Longest Taxi on Record (?)

The *Palestine News* reports that a British aviator was forced by engine trouble to land ten miles inside the Turkish lines. His engine was misfiring, but produced sufficient power for taxi-ing and short hops but not for flight; presumably the valves of two or three cylinders had broken or stuck. Anyhow, the pilot did not give up hope, and succeeded in taxi-ing the whole way to the British lines over the level sand. *En route* he crossed a Turkish encampment, and his undercarriage brought away a clothes line and a number of Turkish shirts. The pilot was attacked by several detachments armed with rifles and machine guns, but they invariably fled when he charged the gun. Two or three German pilots dived and fired bursts at him, but luckily hit no vital part.

◆

AIRMEN MOTOR CYCLISTS

Jan Olieslagers, of the Belgian Army, who has just been credited with felling his sixth Hun plane, is the erstwhile pacing motor cyclist who created wonderful records on the Continent nine or ten years ago. Just as he was the crack motor cyclist of Belgium in those days, he is the leader now of the Belgian air fighters.

Jan Olieslagers, of the Belgian Air Force.

The R.A.F. House Magazine.

The Royal Air Force House Magazine is not to be. Final approval was not forthcoming, and, consequently, the amount received in subscriptions is being handed over to charitable institutions.

◆

Talk of Sparking Plugs!

Some most wonderful results are now being obtained from British-made plugs on aero engines. When peace days return, plug troubles on motor cycles should prove an absolute rarity.

◆

Trimming Winches.

Some modern aeroplanes, especially those of great size, are equipped with trimming winches, by means of which the pilot can set the controls permanently to correct a tendency towards nose or tail heaviness, or to flying with one wing down, thus relieving his muscles of the strain of holding the machine.

◆

The Late Lt. F. M. C. Houghton.

We have received further details of the sad death of poor Frank Houghton, to whom we referred in the Aviation Section in last week's issue.

He was flying a "Camel" single-seater scout on an important test, a type on which he was very proficient, and also very keen to fly. "He was doing valuable work at the time," so his C.O. writes, "and was killed instantaneously, his machine hitting a tree at full speed. He had been writing figures recording the results of his observations, certainly within a minute or two of his death. He was a very popular officer, and we all feel his loss."

◆

Women Pilots.

Mrs. Clarence Winchester, wife of the well-known writer on aviation matters, thinks that women can make quite good pilots. She is of the opinion that anyone who can ride a motor cycle or drive a car ought to make a good pilot, and she quotes that motor cyclist of early days, Mrs. Maurice Hewlett, and two other lady pilots, Mrs. de Beauvoir Stocks and Mrs. Buller, while we may also add the name of Mademoiselle Hélène Dutrieu, who was one of the first ladies to fly.

In the *Daily Mail* Mrs. Winchester expresses an opinion which we have seen stated before, namely, "that horsewomen should make even better airwomen, as there is no finer training for the air than horse riding." This is an opinion with which motorists will find it hard to agree, though, of course, it may be perfectly true.

FLYING FACTS AND THEORIES.

Variable Camber and the Speed Range.

By W. G. Aston, A.F.Ae.S., A.M.I.A.E.

An aeroplane "stalls" when it reaches a certain minimum speed because for its support the angle of incidence of the main planes has had to be increased to such an extent that the streams of air refuse to follow their upper surface. This first of all very considerably reduces their lift, and, secondly, enhances their drag, with the result that two agencies come simultaneously into action, the combined effect of which is an immediate loss of support.

Just as a human being, whilst suffering no discomfort from a gentle push—which is simply a slow rate of acceleration—objects very strenuously to being run into by a motor car and becoming the victim of a very rapid acceleration, so particles of air which will behave in quite a docile manner if treated tenderly become, when handled roughly, fractious, contrary, panic-stricken, and thoroughly disobedient. They *must* be humoured; persuasion, not force, is the only policy; and the aeroplane designer must therefore approach the problem of their efficient deflection with considerable diplomacy. He has to bear in mind in scheming out his plane contours that, although he can bend more or less to his will those air particles which flow along the under side, their fellows which follow the top curvature are susceptible only to cunning coaxing. Let him, or the pilot, make the angle of deflection too sharp by but one degree, and these independent gentry will promptly go on strike. When they lay down their tools, as it were, the machine stalls.

Fig. 1.

The Contour for High Speed.

Now it is highly desirable that an aeroplane should be both fast for covering distance and slow for landing and getting off the ground, as well as to give the aeroplane the capability of keeping up in case of partial engine failure. For the first purpose a small angle of attack is essential, otherwise the main planes will offer too much resistance for the engine to overcome, and that being the case it follows that the curvature, or camber, of the planes must also be slight, otherwise the air particles will refuse, in view of their speed, to be coaxed into following it. Thus we get, as set out in diagrammatic form in fig. 1, the sort of plane section and angle suitable for highest speed. It will be seen that it is very nearly flat, and that the leading portion is practically parallel to the line of air flow. The curvature also is such that the air is gently—that is to say, progressively—deflected downwards. The acceleration being "comfortable," so to speak, the air does what is required of it and follows the plane contour fairly faithfully.

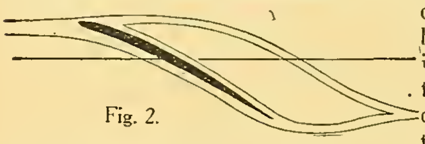


Fig. 2.

Low Speed Flying.

Now supposing we apply the conditions of low-speed flying by setting this same plane at a much bigger angle, as shown in fig. 2, the downward acceleration imparted to the air is now very rapid, the air becomes uncomfortable and refuses to follow the top surface. At the same time that which impinges on the lower surface is deflected very violently. The result is that lift is greatly diminished, and drag is immensely enhanced.

Keeping the angle of incidence the same, these conditions can be much ameliorated by altering the camber and making the section somewhat as shown in fig. 3. The change in curvature now allows a gentle treatment of the air, for once more the acceleration is relatively slow, and, what is of even more importance, it is progressive. The coaxing method is now in evidence, for not only will the air now consent to follow both surfaces, but when finally dealt with, it will have a more directly downward flow than in the previous case. In short, the lift of the plane will be increased, whilst the drag will be reduced.

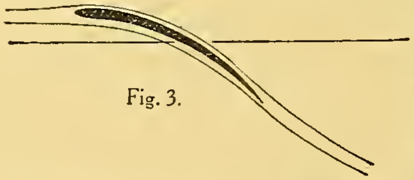

Fig. 3.

It is obvious from the above simple considerations that the ideal aeroplane must embody some contrivance whereby the camber can be varied in flight so that all conditions of speed and power can be complied with in the best possible manner.

The Advantages of Variable Camber.

It may not be generally realised, but it is none the less a fact, that, even with such power plants as exist at the present day, machines could be made to attain a speed of over 250 miles an hour on the level, but as in the absence of variable camber this would mean

Flying Facts and Theories.—

a minimum landing speed of about 150 m.p.h., it is sufficiently clear why they have not been actually produced. They would be unquestionably flyable, but their successful landing would require a Burroughs and Watts aerodrome about the size of Richmond Park, to say nothing of extraordinary skill on the part of the pilot. Given, however, an adequate variable camber mechanism, and the landing speed could be reduced to 60 m.p.h. or thereabouts—a speed rather less than that often employed at the present time.

Is a Variable Camber Realisable?

It is only fools who say that any engineering feat is impossible; whilst therefore one can safely say that the solution of the variable camber problem is an exceedingly difficult one, it is certainly too much to say that the obstacles are insuperable. A brief consideration of the conditions to be fulfilled will suggest the compression strength of the nut to be cracked. The plane section at all cambers must be perfectly rigid; both upper and lower fabric surfaces must be taut and smooth in curvature; the mechanism must be immensely strong, extremely light in weight and certain in action; the centre of pressure of the plane must be disturbed as little as possible; the rigidity of the whole wing structure must not be impaired; the variation of the camber must be accomplished fairly quickly and be completely under the control of the pilot. The inventor who successfully solves the problem will deserve the thanks of airmen and a place in the history of aeronautics.

A Ford Post-war Aeroplane?

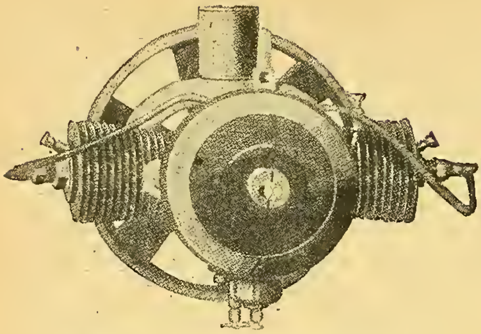
A Future Order:

"Please send me one of your Aeroplanes, for which I enclose cheque for £100."

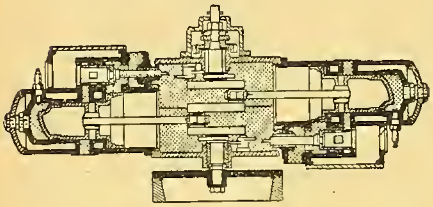
As Henry Ford has been the fairy godfather of impecunious motorists, so he may yet prove to be the consolation of the man of moderate means, who thirsts to own his own aeroplane. At recent exhibitions in Trafalgar Square some of us saw the world's smallest aeroplane, which is presumably obsolete and a washout for war purposes, or it would never have been stuck up for all the world and his wife, including uninterned Boches, to take notes of. But I noticed with interest that it was propelled by a glorified motor cycle engine, made by a motor cycle engineer. I saw no reason why such an engine should use much petrol per hour, or cost more than £30 to make in quantities. Henry Ford could surely turn out this 'bus in quantities at between £100 and £150 a time. Its wings could be taken off, if so designed, by knocking out a couple of pins on each side, and slipping a bracing wire or two. The whole 'bus could then be housed in an ordinary light car garage. As the dear old training "Rumpety," or Maurice Farman, does its 80 m.p.h., this wee plane should be fast enough for ordinary purposes, since it carries no weight, and its lines are clean. Moreover, being well powered for its weight, it should get off the ground with a very short run, and the private owner's one problem with it would be to find a safe landing place, until such time as the police allow us to use quiet suburban roads for the purpose. Oh dear! Why was not I born forty years later? All the real fun lies ahead.

D.

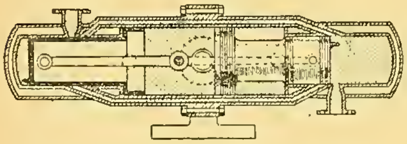
With the American Expeditionary Force in France. American mechanics assembling 'planes at an aviation school in France. (*Official.*)



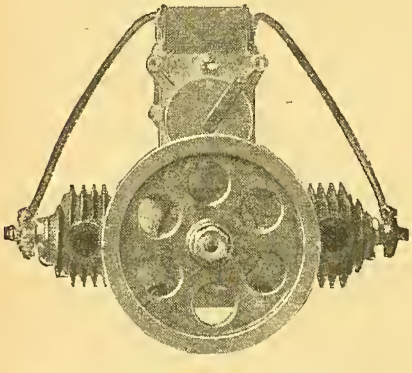
The flat twin two-stroke engine of the American Greyhound cycle car, which, with friction transmission, it was intended to market at a figure in the neighbourhood of £50. Note the fan opposite the flywheel.



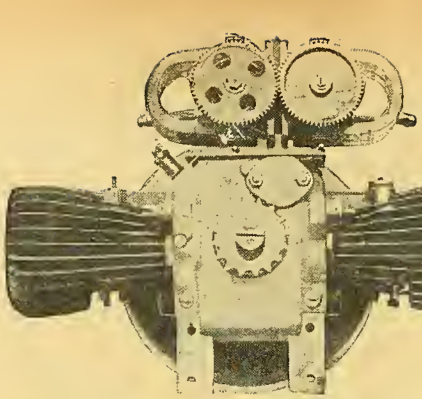
The M.I.P., which has 180° cranks and embodies truncated pistons and piston valves. Crank case compression is used for scavenging only, the mixture being admitted to the working cylinders by rotary or piston valves.



The Victoria, probably the first of the flat twin two-strokes. Truncated pistons are used to provide the initial compression, the lower half of one cylinder acting as a pump for the other cylinder. A single-throw crank is embodied.



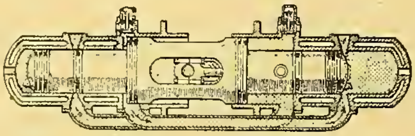
The Dwarf engine, a flat twin two-stroke designed for an ultra lightweight motor cycle, which it was hoped would weigh no more than 70 lb. The design embodied mechanically operated exhaust valves.



An experimental Douglas two-stroke flat twin built six years ago. Note the twin magnetos geared together.

It is a common mistake among those who do not closely follow the mechanics of the motor cycle engine to suppose that any two-stroke engine, because it fires on every down stroke of the piston, must necessarily split up the torque of a similar engine of the four-stroke type. The majority of flat twin two-strokes have, however, a torque similar to that of a four-stroke engine of the same general type, such as the Douglas.

To explain this to the uninitiated a chart is given herewith. The vertical lines in this chart each represent 90°, therefore four of them represent 360°. The dark dots indicate the firing instant, the horizontal lines show the intervals between explosions in each cylinder, and the heavy lines the firing intervals of the complete engine. From the chart it will be noted that, while the two-stroke single has intervals of 360°, exactly half those of a four-stroke single, the flat twins with 180° cranks (which is accepted practice) are exactly alike, because in both cases the pistons are at the top of their stroke together, but in the case of the four-stroke the cylinders fire alternately, because two revolutions are required to complete the cycle.

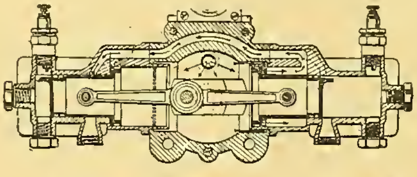


The Rankin-Kennedy engine, having two truncated pistons connected together and employing only one connecting rod. The crank works inside the sleeve connecting the pistons, which is slotted at each side for the shafts.

Flat Twin Cranks.

In the case of the vertical twin the firing torque, so bad in the four-stroke type, is converted to one equal to that of a four-cylinder four-stroke by the introduction of the two-stroke cycle.

To obtain this result in a flat twin it is necessary to have a single crank throw, which means that the



The Duttlinger engine, a recent French patent, in which truncated pistons are embodied, drawing their charges of gas from the crank case through ports exposed at the bottom of the stroke.

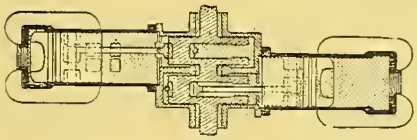
does not vary, hence means have to be employed to provide initial compression for each cylinder separately. It will be seen that in the Kimberley design a blower is used, while in the Wilks-Hartshorn engine the ends of the cylinders are closed and piston rods embodied as in steam engine practice, while in the Duttlinger patent truncated pistons are used. In the Spencer patent specification, the crank case is shown as being divided to provide a separate compression space for each cylinder.

Balance and Torque Again.

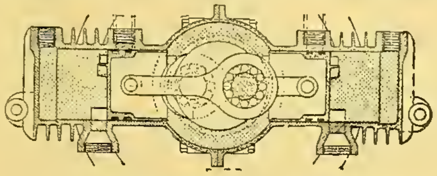
When everything is considered, it is not surprising that many designers of flat twin two-strokes have been prepared to sacrifice the more even torque of the conventional four-cylinder engine, given by the flat twin two-stroke with 360° cranks, to obtain the balance advantages of the flat twin with 180° cranks.



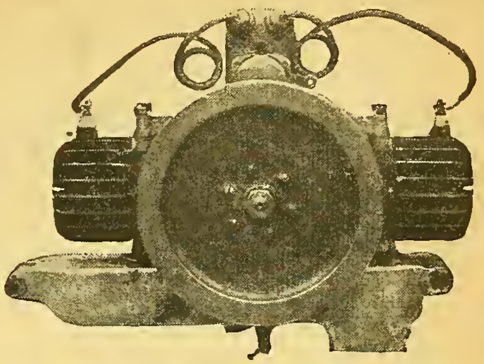
The Spencer design, which may best be described as two single-cylinder engines with their crank cases reversed and placed side by side. The impulse effect is the same as an engine having a single-throw crank.

One is constrained to ask, Why introduce a flat twin two-stroke if the firing torque is only the same as the four-stroke, which is regarded as a superior cycle? The answer lies in the fact that in the four-stroke engine the power is given off at each end of the engine alternately. In the two-stroke engine of this type, both cylinders fire simultaneously. Therefore, a perfect two-stroke flat twin should be nearer to the ideal than a perfect four-stroke engine of this type.

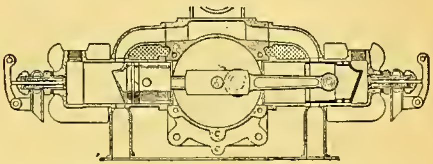
In the minds of the majority of designers the greatest advantage of the two-stroke engine is its simplicity on account of the absence of valves and



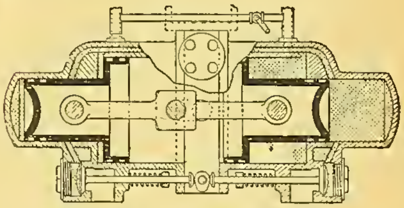
The Roots design, the main idea of which is to reduce the number of parts. It will be noticed that the crank case is formed by extending the cylinders. Staggered connecting rods are used, permitting the cylinders to line.



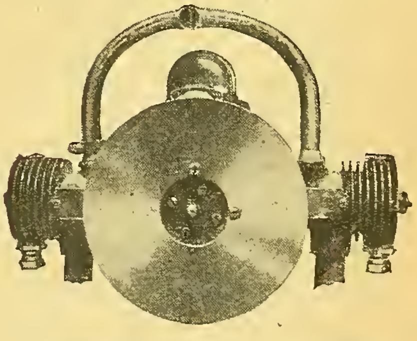
The Connaught engine, which, like the Levis, has 180° cranks. The transfer passages are formed in the magneto platform, which is also the crank case cover. Note the aluminium box-shaped silencer by which the engine is carried in the frame.



The Kimberley engine, designed for the James Cycle Co., Ltd., another engine with single-throw crank. In this design initial compression is provided by a blower pump, which is part of the crank case.



The Rowe engine, a recent patent embodying truncated pistons and a single-throw crank. The invention includes mechanically operated exhaust valves. In the transfer pipes there is a rotary valve by means of which the whole or portion of the compressed charge in either of the pump cylinders may be conducted into the other compression space instead of into the cylinder, thus permitting the power output of the engine to be varied at will.



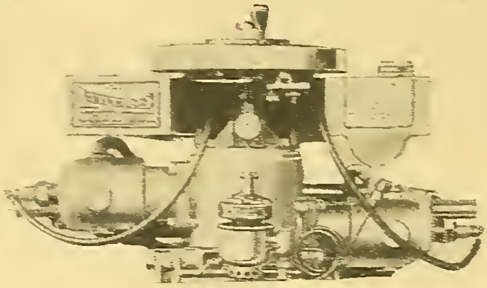
The Bullet engine, which embodies separate cranks connected by means of a dog clutch in a central bearing, which divides the crank case into two separate chambers for initial compression.

The Flat Twin Two-stroke.—

valve gear. Several recent designs, however, embody valves, both of the poppet and rotary types.

There are several difficulties for designers and makers to overcome. It may be remembered that the Scott racing engine has a rotary valve to distribute the gases, under compression in the crank cases, equally to the two cylinders. With the flat twin the conditions are not exactly the same, but the need for some such device appears to have been appreciated by more than one designer of a flat twin two-stroke. Again, the ignition problem is not easily solved with this type of engine, since it is necessary to provide two sparks absolutely simultaneously, and probably the double pole plug may be of assistance at this point.

At the time war broke out plug and magneto experts differed as to whether it was advisable to use a double pole plug. The magneto makers affirmed that this system of ignition placed undue strain upon the magneto. It will be noted from the illustrations that Messrs. Douglas Bros., in their experiments with flat twin two-strokes, fitted two magnetos. The greatest efficiency is hardly to be expected from these methods, while the setting of the magnetos must have called for almost superhuman patience and perseverance if anything near the possible maximum efficiency were to be obtained.



The Evinrude portable boat engine, a representative of many such engines used for marine purposes in the United States. Note the staggered cylinders.

The accompanying illustrations show some of the designs of flat twin two-strokes, while several are from photographs of engines that have been made.

At least one engine of this type is in use by His Majesty's Government, and, no doubt, we shall hear more of this when the war is over. In the meantime, it is interesting to take stock of the various existing designs, from which we may be able to judge the trend of thought behind what may be a standard type of motor cycle engine in the future.

THE "BEST" GEAR RATIO.

Some Opinions on a Rather Controversial Subject.

FEW riders seem to realise the fact that as a petrol motor depends for its power on the number of revolutions per minute at which it runs, a lower gear gives a greater output of power than a high one. To take an example, suppose we have a 3½ h.p. engine which when geared 4 to 1 gives 4 h.p. on the back wheel, if we lower the gear to 5 to 1 the h.p. with the same throttle opening will now be very nearly 5 h.p. The question now is, what is the best ratio to use in practice, and the answer to this depends on whether the rider requires the best *average* speed, *i.e.*, the maximum distance covered in a given time, or merely the best *maximum* speed for a short distance.

The low-geared machine will give the best average speed because its greater number of revs. means a greater power output, and also because it will take most hills "on top" instead of having to change down to an unnecessarily low gear, as would be the case of a high-geared machine. If we assume that on average "give and take" roads, two-thirds of distance covered in a day will be either level country or uphill, it follows that a low-geared machine will score over two-thirds of the distance, whilst a high-geared machine will only score over one-third of the distance, *i.e.*, when running over down grades.

Conclusive Experiments.

Some years ago I carried out a number of experiments with a well-tuned 5½ h.p. combination, fitted with a hub gear and Philipson pulley. This arrangement gave practically any gear between 4 to 1 and 14 to 1. I found that with a top gear of 4 to 1 the engine was practically useless, except in down grades—it had "no life," and the pull was extremely jerky. The prejudice against "one lungers" in many quarters is due very largely to the fact that most sidecar combinations are sent out by makers very much overgeared; if properly geared the torque of a well-balanced single is good enough for anyone outside of a sanatorium (or asylum). As a result of the experiments, I proved conclusively that the best gear for a moderate-powered combination was 6-6¼ to 1 for top gear, and such a gear gave *best average speed over a long run.* The low top gear also means far more flexibility and longer life of engine bearings.

So long as we have a speed limit of 20 m.p.h. in force it is absurd to send out machines geared for excessive speeds—only, in fact, fit for the track. The low-geared machine will make by far the best all-round combination for touring work, which is what most sane riders require.

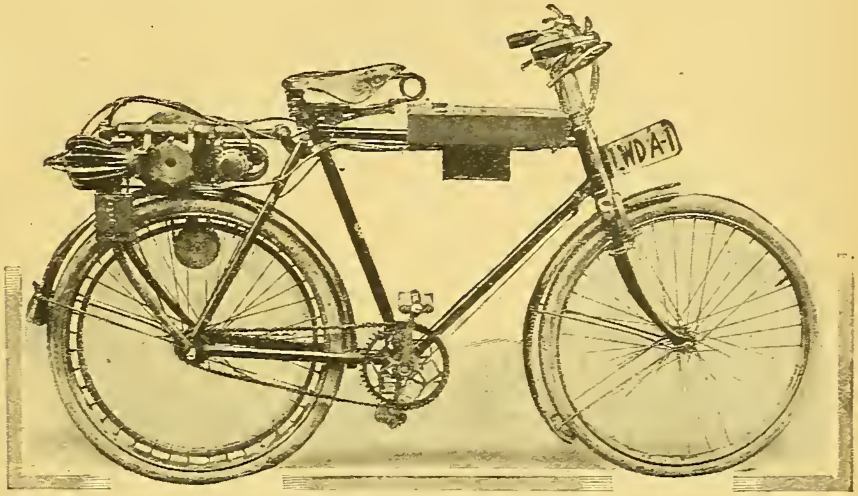
Summary.

The same argument, of course, applies to pedal cycle gears, and the man who uses a single gear of, say, 120in., although he can make good time downhill, or before a gale of wind, will *not* be able to cover as much ground in a day as a rider on a low-geared machine. To settle, once for all, the question of "best" gear, therefore, it seems to me only necessary to grasp the two facts mentioned: (1.) That power output depends on *number* of revs. per minute. (2.) That two-thirds of distance covered in a day is either level or uphill work, and so to the advantage of a low-geared machine.

When a large twin is used for solo or light sidecar work it is, of course, advisable to gear higher, for the simple reason that maximum possible power output is seldom or never required. My arguments refer chiefly to the 4-6 h.p. combination. M. HITCHCOCK.

THE ZEPHYR MOTOR ATTACHMENT.

AN IMPROVED MODEL.



The improved model Zephyr motor attachment. The engine is a two-stroke of 1¼ h.p.

It was in the issue of November 18th, 1915, that we first described the Zephyr attachment, which is handled by the London and Westminster Industrial Syndicate, Ltd., 8, Victoria Street, London, S.W.1. The outfit then underwent a considerable amount of development, and was again described in the issue of February 22nd, 1917—a description which went at considerable length into the method of carrying the engine and the transmission—but since that date the Zephyr has been still further improved, and now has reached the stage at which it may be said to have attained practical finality in design.

The engine was originally attached to the luggage carrier, but it was found that it can be more conveniently and more simply carried on a single tube extending from a lug clipped on to the top of the saddle tube of the bicycle frame. It is fastened on to the lug by means of a bolt, and at the rear end, as can be seen from the picture showing the carburetter side, it is suspended on a telescopic spring device which acts as a shock absorber. The engine is finally supported by means of a supplementary pair of forks, as clearly shown in the illustration.

The engine is a two-stroke, 2$\frac{1}{16}$in. (52½ mm.) bore and stroke, and develops 1¼ h.p. Larger radiating fins, so as to assist cooling, are now fitted and there have been slight modifications in design. In this engine, the gases are transmitted from the crank chamber to the combustion chamber *viâ* a port in the piston. The exhaust port has also been brought a little to the rear.

Mr. H. B. Molesworth, M.Inst.C.E., the well-known engineer, who is acting as consulting engineer to the Syndicate, informs us that the engine has been greatly improved both as regards flexibility and power.

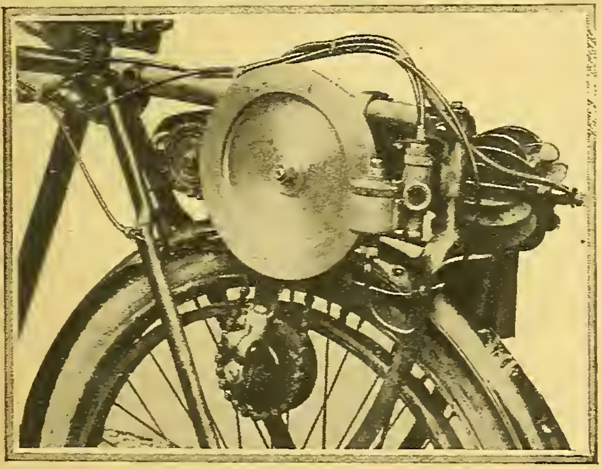
An Interesting Transmission.

It may be remembered that a most interesting feature of the Zephyr attachment is the transmission, and in this a slight improvement has been effected. There is now no shock absorber on the transmission pulley, which is driven by chain from the engine and hung on a swinging arm, and, instead of a take-off spring being provided, a large Bowden lever controlling two wires, the action of which is to swing the pulley backwards and forwards, is clipped on to the off side of the handle-bar. When the pulley is pushed forward it is in the position in which the back wheel can best rotate the engine and start it. The central position is neutral, while if the lever be pushed forward so as to bring the pulley to the rear the drive is communicated from the engine through the belt rim to the back wheel. There is a tendency for the friction wheel to run towards the rear of the bicycle against the belt rim, and, in consequence of the jamming action, sufficient drive is attained to transmit the power of the engine to the road wheel without slipping.

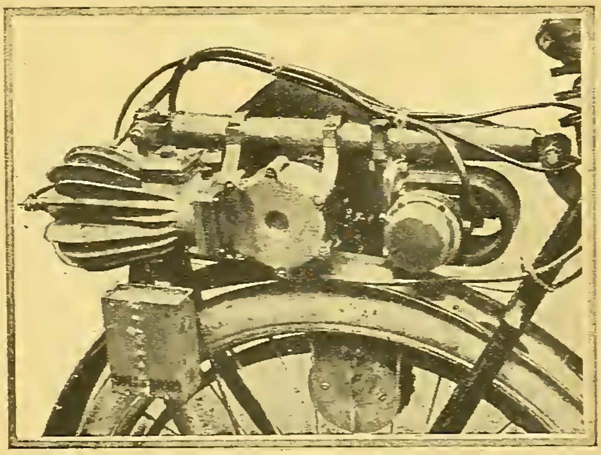
The engine is lubricated by the petroil system, and the tank shown on the top tube is not in the normal position, as in future models it will be carried over the engine and all control wires will be hidden.

The attachment might be adapted to bath chairs so that one wheel could be driven by the motor and the chair steered by means of a tiller.

We tried the machine for a short distance and found the engine capable of attaining a high number of revolutions; but we would suggest that the control be arranged in the standardised fashion, namely, the transmission control on the near side of the handle-bars and that for the carburetter on the off side. The engine has no compression release, consequently the control is entirely by the throttle and air levers.



Carburetter side of the Zephyr power unit. The shock absorber is immediately behind the carburetter, interposed between the supporting tubes and the auxiliary fork.



The engine is suspended on an arm, one end of which is bolted to a special lug beneath the saddle, the other end being bolted to an auxiliary fork.

MILITARY NOTES.

DEATH OF CAPTAIN BUSBY—A PIONEER DESPATCH RIDER.

MILITARY CROSS FOR A FORMER D.R.

CAPT. H. H. BERLANDINA, R.E., has been awarded the Military Cross for services on the Italian Front. Capt. Berlandina was a despatch rider with the original army in France.

* * *

THE LATE CAPTAIN VERNON BUSBY, R.A.F.

WE have a very sad duty to perform in recording the death of Capt. Vernon Busby, R.A.F., who was killed accidentally while flying near London recently.

Capt. Vernon Busby, R.A.F., who was killed whilst flying.

Capt. Busby was one of our best known motor cyclists, and before the war was the skilful rider of a 3½ h.p. Sunbeam and other machines, and was connected with the Aston Motor Accessories Co., Ltd., the manufacturers of the Amac carburetter. He was a consistent performer in competitions, and a well-known *habitué* at all the Brooklands motor cycle race meetings.

When war broke out (as he was in the Special Reserve he was, of course, mobilised at the outbreak of hostilities) he was sent with a number of other motor cyclists to Ireland, and Busby was the first wounded despatch rider we visited after the Battle of Mons, and at Le Cateau he was accidentally wounded by a rifle bullet. At that time he was a corporal, R.E. Signal Section, and for more than a year he continued in this branch of the service, eventually being granted a commission, and finally ending his career in the R.E.'s by being appointed one of the officers at an R.E. training centre. Then he was transferred to the R.A.F., and for some time suffered from exceedingly bad health, but he eventually recovered and later became a pilot, and it was while acting in this capacity that he met with his sad end.

His accounts of the early fighting were distinctly interesting, and in our first interview with him he described how motor cyclists during the retreat were instructed to go out in pairs, with one hand on the handle-bars and the other carrying a revolver, while orders were given to them to cut telegraph wires as the troops retired.

Capt. Busby will be sorely missed in competitions when motor cycling again becomes general. His war record was one to be proud of, and he certainly did yeoman service in developing the motor cycle prior to the war.

* * *

D.R.'s OF THE R.G.A.

A GUNNER of the —th Siege Battery of the Royal Garrison Artillery writes to us under the *nom-de-plume* of "Venus." He discusses the relative hardships of the despatch riders attached to the Artillery and those of the Royal Engineers.

He says: "I have been a most interested reader of your most excellent journal *The Motor Cycle* for the last four years, and noticed how frequently the despatch riders of the R.E.'s are mentioned. There are other D.R.'s in France who deserve mention also. Every Siege Battery in France has with it two combinations and two solo machines. The Heavy Artillery Groups or Brigades have about two solos. The combinations are either Clynos or the Douglas 4 h.p. The solos are either Triumph or the Douglas 2¾ h.p.

"A few batteries are allowed A.S.C. D.R.'s, but nearly all batteries prefer their own men. The Battery D.R.'s are all issued with clothes, waterproofs, leggings, etc., exactly similar to the famous R.E. D.R.'s.

"The respective 'cushiness' of these jobs is often discussed: the R.E. anywhere between Rouen and the Corps H.Q.R.S., or the R.G.A. who rides between the heavily shelled battery positions and the Brigade H.D.R.S. or Heavy Artillery Groups, where the roads are without repair and badly shell-holed.

"Another little item is that the R.E. gets an everyday opportunity of getting small repairs executed and broken parts exchanged. Now, the R.G.A. D.R. has anywhere between four and forty kilometres to go, according to his Front, before he is able to get the necessary at his workshop (A.S.C.).

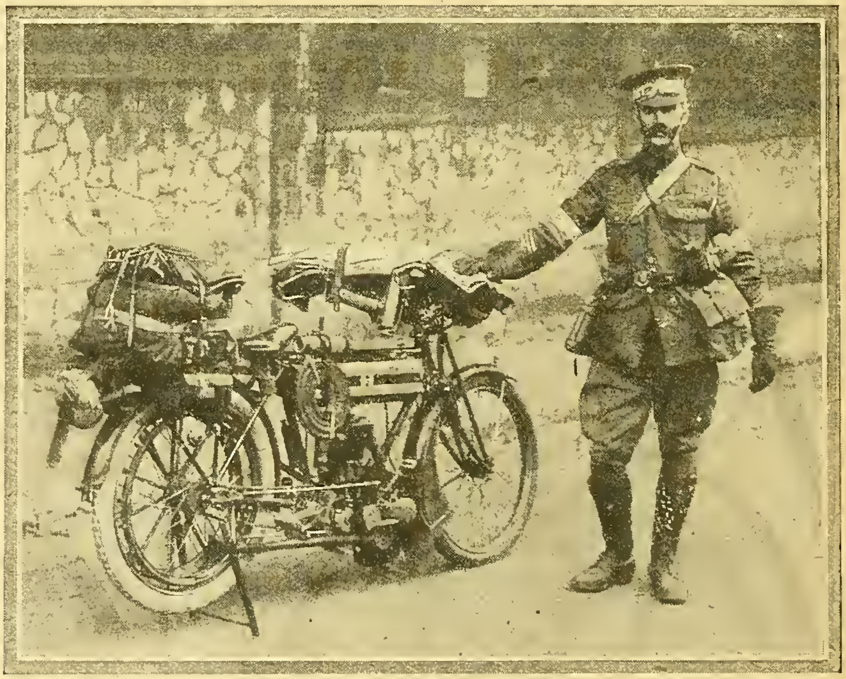
"In fine, all we ask is that when people talk of D.R.'s, do not forget that there are other units in France beside R.E.'s who do risky and useful D.R. work.

"I wish the 'Blue 'Un' every success as a most top-hole journal."

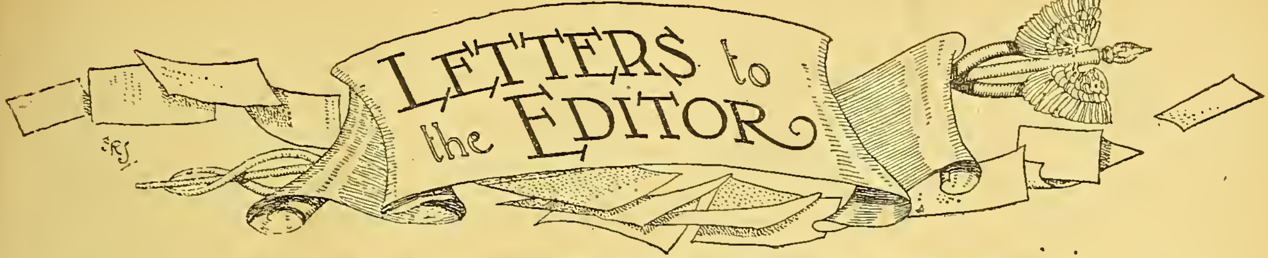
* * *

VETERAN MILITARY MOTOR CYCLIST.

WE have received a few particulars concerning Lt. Longley, who has had thirty years' continuous service in the Royal Engineers, and was among the first to see the possibilities of despatch riding on motor cycles. He went out with the original Expeditionary Force in 1914, and fought from Mons to the Marne. Then forward again to the swaying struggle and imperishable glory of Ypres. He has since obtained a commission, and is still on active service. The photograph we reproduce shows Lt. Longley (at this time he was a sergeant) with a Triumph and full kit ready to leave for France in 1914.



Lt. Longley, R.E., with full rig, about to leave for France as sergeant in 1914. He was one of the first to conceive the idea of motor cycle despatch riding.



LETTERS to the EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

DIFFICULT STARTING.

Sir,—As a B.S.A. rider, I would like to thank Mr. Ellison for his letter, and would suggest that the B.S.A. Co. reproduce his instructions as they stand in their booklet. In future the recording angel will find a material decrease in his labours so far as I am concerned! Any more tips from Mr. Ellison would be welcome. GILBERT ELLIOT.

TIMING MECHANISM.

Sir,—With reference to the most interesting article on "Timing Mechanism" on page 488 of *The Motor Cycle* of May 23rd, I should like to point out that the Bradbury engine is incorrectly classed. This engine is mentioned in Group 3 as having "two cam wheels with *external* cams," whereas it embodies two cam wheels with *internal* cams, and should therefore come under Group 4.

D. J. McDOUGALL.

STUNT FLYING.

Sir,—The sketch on page 569 in the issue of *The Motor Cycle* for June 13th, which purports to illustrate an aeroplane rolling, is so inaccurate that I cannot refrain from offering a protest. This picture shows the aeroplane simply rotating on its fore and aft axis, which is not the case in actual practice. If it were so, then it is obvious that during this manœuvre centrifugal force would tend to throw the pilot out of his machine, whereas, as a matter of fact, during the roll the pilot is actually held in. As I pointed out in my article some six weeks ago, a roll is practically a loop pulled out axially, and therefore involves control on the elevator as well as on the ailerons. Since "Torque" has not mentioned this point, his description is apt to be misleading. W. G. ASTON, A.F.Ae.S., A.M.I.A.E.

R.A.F. MECHANICS.

Sir,—For the sake of the "butcher, baker, tinker, and tailor" who wish to be classed as technical, I will define a mechanic. He is a man who can do turning, fitting, planing, milling, toolmaking, hardening, tempering, and (if necessary) pattern-making and carpentry. Can any of your correspondents claim these abilities? In my opinion, only those qualified in the above can claim to be air mechanics; the rest should simply be plain privates. As to their own repairs, many a man in pre-war days did his own repairs, but in profession was in any trade other than engineering, and would not have cared to have been described as a mechanic. In writing this letter, I am voicing the opinion of other mechanics, all of us old hands, and not war-time mechanics. Hoping your correspondents will deal leniently with us, FIVE PRE-WAR ENGINEERS.

London, S.E.

A TIP FOR TIMING A TWO-STROKE.

Sir,—I often see queries in your paper *re* the timing of two-strokes. Naturally, the retiming of these interesting little engines is always attended with some anxiety, as a few millimetres either way means a lot to an engine with 2,000 firing strokes per minute. Some of the newer machines have an indication mark on the outside flywheel which simplifies the matter immensely. Riders of older machines of the two-stroke variety, however, whose machines bear no such mark, would find the following "tip" useful for testing the timing:

With the machine on the stand, inject a little petrol, and fire off by pulling over the back wheel by a firm hand grip on the tyre in the usual way. If the timing is correct the wheel should be fired *backwards* out of the hand with the ignition lever in every position except fully retarded, in which position (only) the wheel should be fired forwards. Keep clear of the mudguard with the wrist, or a nasty cut is the result.

It takes a bit of fiddling sometimes to get this result, but the time is well spent, and results in a cooler engine, greater speed, more power on hills, and improved consumption of fuel and oil. J. DODD.

THE FOUR-CYLINDER F.N.

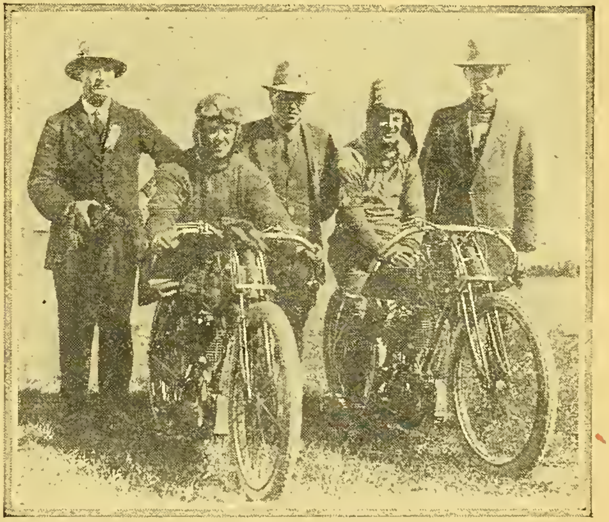
Sir,—In reply to "Canterbury" in *The Motor Cycle* of June 13th, the F.N. could be obtained fitted with gears of approximately 5¼ to 1 and 10½ to 1 for solo use, or 6 to 1 and 12 to 1 for sideacr work. With the 5¼ to 1 gear a speed of 56 m.p.h. can be *touched* when the engine is in good order, but 45 m.p.h. is the usual limit for any distance because of the automatic inlet valves. With the 6 to 1 gear a speed of about 50 m.p.h. for a short distance or 40 m.p.h. sustained is as high as can be expected. W.B.

Sir,—I have pleasure in replying as follows to the queries of your correspondent "Canterbury," *re* four-cylinder F.N.

The gear ratios of 5.9 and 11.8 to 1 on his machine are intended for sidecar work. The solo gears are 5.4 and 10.8 to 1, though the first mentioned are quite suitable. If he wishes to change the ratios it can only be done by altering the two gears in the bottom bracket which carry the drive from the clutch out to the gear box. He will find these now have seventeen and twenty-five teeth. The makers supply another pair with eighteen and twenty-four teeth, which will give the required alteration.

Should your correspondent require any more information or hints on the F.N. I should be very pleased to supply it.

ERIC CAUDWELL.



Competitors in the New Zealand Red Cross Motor Carnival. The rider on the left is A. E. Woodman (B.S.A.), the one-legged motor cyclist, and winner of the middleweight New Zealand championship. Woodman, it will be remembered, lost his leg in consequence of an accident whilst practising for the 1910 T.T. races. The rider on the right is J. A. Karton (B.S.A.), second in the New Zealand championship.

CAIRO TO JERUSALEM.

Sir,—In your issue of March 14th, under the heading of Current Chat, we noticed a paragraph stating that a Church Army organiser had recently undertaken a motor cycle ride from Cairo to Jerusalem.

Would the Church Army organiser oblige with a detailed description of his ride, as, so far as we know, this is the longest motor cycle ride ever attempted over the Sinai Desert, and would be welcomed by all D.R.'s on this front, who have had experience of real sand riding?

The Triumphs out here are standing up to the work magnificently. A stronger fork spring, stronger main bearings in the gear box, and footrests further back would be welcomed by TWO PALM TREES.

Palestine.

A CURIOUS CASE.

Sir,—With reference to a letter by H. C. Cousins, R.M.A., in your issue of May 16th, I have also come across a Thomson-Bennett magneto (operated by hand for starting) which gave a spark without a carbon brush bearing on the collector ring. On examination, I found the brush holder (made of vulcanite) had a brass bush, in which worked the carbon brush. Presumably the high-tension current jumps from the collector ring to the brass bush, which must touch, or almost touch, the high-tension cable.

I notice "S.A.E.G." (May 30th) complains of his engine starting easily from cold, but not when hot. This happened to me once also, and on taking down the magneto I found that water had got inside, all round the armature. Exactly why the engine started easily from cold, I do not know, but a thorough drying of the magneto parts cured the trouble. G. BAGSHAWE.

B.E.F.

THE POINT OF MAXIMUM EFFECTIVE PRESSURE.

Sir,—In reply to the letter of Mr. H. S. Leftwich, in your issue of May 30th, the point in question occurs when the crank has moved about 30° from the top dead centre.

This is the point at which the *turning moment* on the crankshaft reaches its maximum value. As the crank rotates beyond this point, it certainly gets into a more favourable position for rotating the shaft, until, when the crank and connecting rod are at right angles, the most favourable position is reached, but what is gained in this respect is more than lost by the rapidly falling pressure.

The value of 30° is given for an engine running *slowly*, so that no considerable inertia forces are generated. When an engine runs at a high speed, the inertia of the piston and connecting rod modifies the piston pressures in such a way that the maximum turning moment occurs at some angle rather later than 30°, the exact value depending upon the magnitude of the various quantities involved.

J. H. SINCLAIR.

A BAFFLING EXPERIENCE.

Sir,—With reference to the mysterious and baffling occurrence to Mr. Chapman's machine, perhaps my experience may be of assistance.

My machine, a 6 h.p. twin Bradbury (we hear little of this machine, but it is second to none) with a Splitdorf magneto, behaved in exactly the same way. Having arranged to convey a friend from here to Selsey, I was quite unable to get a start. The spark appeared quite in order, plugs clean, magneto points set to a hair. The result was nil after two hours' hard work. Next day I emptied the tank and refilled with petrol instead of half Binks and half petrol. After half an hour I eventually got a backfire, and in the end the machine ran quite well. This was after heating the plug points almost red hot in a fire. The same thing occurred soon afterwards, but a new contact maker platinum point set me right once more.

It was pretty obvious from the speedy manner in which the platinum wasted away that the magneto was wrong.

It was then sent by our local garage proprietor to London to be overhauled, and the result is marvellous—not an atom of trouble from that day to this. What was done to the magneto I do not know, nor have I enquired. The result is quite sufficient, for the cause was beyond me. I even tried another carburetter, with very poor results, returning to a B. and B. top feed. I trust this may help Mr. Chapman.

Midhurst. S 5780.

[The indications point to condenser trouble.—Ed.]

WHAT IS A CYCLE CAR?

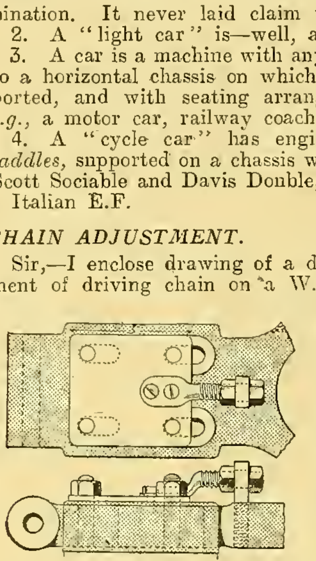
Sir,—I see "Ixion" believes in the coming of the cycle car. Does he know what a cycle car is? I have been following the struggles of a certain motoring weekly to define a motor cycle, cycle car, and light car. I am none the wiser yet from their definitions, but I know what *I* mean by a cycle car. Allow me to say first that weight, price, passenger capacity, and cubical capacity have nothing to do with the question. The deciding factor is the chassis. I have not yet seen a clear statement of the difference between a motor cycle and car. Let me clear up the point. A motor cycle has a *vertical* chassis, a car a *horizontal* one. This fact appreciated, the definition question becomes easy.

1. A "sidecar outfit" is not any one thing; it is a combination. It never laid claim to any special name.
2. A "light car" is—well, a *light* car.
3. A car is a machine with any number of wheels attached to a horizontal chassis on which the engine, if any, is supported, and with seating arrangements of the chair type, *e.g.*, a motor car, railway coach, or tramcar.
4. A "cycle car" has engine, wheels, and seats, *not saddles*, supported on a chassis which is mainly vertical, *e.g.*, Scott Sociable and Davis Double, the only instances I know.

Italian E.F. G.H.H.

CHAIN ADJUSTMENT.

Sir,—I enclose drawing of a device for the simple adjustment of driving chain on a W.D. Triumph. This is easy to make and quite within the capabilities of the average mechanically inclined reader. It is self-explanatory, gives a quick, easy adjustment, and is well worth fitting to any countershaft model Triumph. I have several machines fitted with it out here, and it is giving every satisfaction.



A device for facilitating chain adjustment.

I have been out here with a supply column since February, 1915, and the arrival of your publication is quite a weekly event. I note the post-war Indian is to be fitted with a very similar adjustment. This of mine has been on the road since January. S. GORDON BARNETT.

B.E.F.

SATISFACTORY TREATMENT.

Sir,—I should like to give the makers of my motor cycle and sidecar some well-deserved praise, both for their benefit and for the benefit of the motor cycling public, and therefore I trust you will publish this letter, and possibly give them (the makers) a slight surprise. The reason is this: Since 1899 I have owned almost every type of motor vehicle from big cars to motor cycles, but have not for some time till this year owned motor cycles again, when I bought a small 2¾ h.p. solo machine, and then exchanged it for a new war model 8 h.p. Matchless, as the other was not up to its work (although an excellent machine) on these bad roads with a sidecar. I must say that I was astonished at the advance which had been made since my 1905 N.S.U.

Now the point is this. During all these years when anything went wrong with the machinery I found the firms concerned rather aggrieved and somewhat bored at having to put things right, and generally inclined to insinuate that the fault lay in my driving or that of my chauffeur, and had nothing to do with any defect in their product. Then followed as a rule a heavy repair bill.

Now, I have nothing but praise for this latest machine of mine; it has done over 2,000 miles, and has had and required less attention than any motor vehicle I have ever possessed, but, being a bit of a Jonah, things always happen to me, and in this case I had some slight trouble with the clutch. I rang up Messrs. Collier and asked them if they could possibly put this right if I brought the machine to their works as quickly as possible, explaining that I was a busy professional man, and unable to spare the use of the vehicle. This they promised to do, and done it was with the utmost despatch. Not only that, but Mr. Collier and his foreman personally superintended the work, and thoroughly overhauled the whole combination and readjusted everything in the twinkling of an eye, and I was sent on my way rejoicing in under two hours, work having been done which would have taken any ordinary garage almost days to do. This was effected by putting a number of workmen on the job, such things as removing the sidecar body being done to see if the front springs were all right, etc. Now, this is first-class treatment, and, to my mind, is an example of how motor business should be carried on, and naturally should I ever purchase another motor cycle after the war (which I probably shall), Messrs. Collier will be the first people to whom I shall apply. The machine is now running perfectly, and, strange to say, I get as much pleasure driving this powerful combination as I did with my previous cars; also I am in much better health than when I owned a car—perhaps a coincidence, perhaps not. Needless to say, I have no connection with Messrs. Collier, and have never mentioned to them that I was going to write this letter.

CLAUDE GOULDESBROUGH, M.B.

MOTOR CYCLISTS AND THE ROYAL AIR FORCE.

Sir,—With reference to the correspondence *re* motor cyclists and the R.A.F., I hope that I shall not be encroaching too much upon the valuable space of *The Motor Cycle*—of which periodical and of *The Autocar* I have never missed one issue during nearly three years out here.

Now, it must be very heartrending to enthusiastic motor cyclists and mechanics who are in the infantry—like myself—to read of this jealousy of men in the R.A.F. I fail to see how R.A.F. D.R.'s can compare tuning up and keeping on the road a P. and M. motor cycle with a 3 ton Leyland motor lorry, and the officials who arranged the different grades knew the game and saw this. In any case, I would exchange places with any of them, and shake hands with myself, but I am not in the Army for what I can get, but to get the war over.

B.E.F. NORTHUMBERLAND FUSILIER.

AN OCCASIONAL "KONK."

Sir,—I submit the following explanation for discussion:

Action.—Detonation before dead centre on compression stroke.

Cause.—Modern petrol of low flash point in combination with high compression engine, six years old design of cooling, and, possibly, hot climate.

Remedy.—(1.) Raise flash point of fuel by using benzole. (2.) Lower the temperature of engine by *(a)* lowering the compression by placing washers under the cylinders and scraping off carbon deposit; *(b)* increasing efficiency of cooling by ensuring as big flows of air and water as possible. If possible clean jackets and radiator.

In this connection petrol is really an unsuitable fuel when used in the ordinary run of air-cooled cast iron cylinders of engines which have a high compression and which are liable to overloading and neglect. With a momentarily perfect mixture the above conditions approach too near the danger point of detonation.

W. R. DEUCHAR (Sec.-Lt., R.E.).

MOTOR CYCLISTS AND THE PETROL SUPPLY.

Sir,—Probably, like most other folk, I am distinctly puzzled to know what I may do and what I may not do under the latest Petrol Restriction Act, and if you can help me, and perhaps help others similarly situated to myself, I shall be grateful.

In February, 1917, I was granted a petrol licence for twenty gallons, which I bought. I also bought about that time approximately sixty gallons of substitute, for which I required no permit. My petrol permit was for pleasure purposes.

I came to the conclusion that rigid economy was and would be absolutely necessary, and, beyond using eight gallons during my holidays, I have strictly confined my riding to business purposes, and consequently have somewhere about thirty gallons left in stock.

I wrote to the Petrol Committee to know if I was permitted to use my machine under the following conditions: My employment is in an engineering works, Government controlled, solely employed upon strictly war work, and the works is situated about twelve miles away from my home. During the war the trains have been curtailed to such an extent that there are only two trains outwards, one ten minutes after the other, and two trains homewards in the evening, and no trains whatever in between in either direction, and my only way home in that case is by going into the City, probably walking a mile or more for an electric car, on which I have thirty-five or forty minutes' journey, and, incidentally, losing from one and a half to two and a half or even more hours by the process. Under the very best conditions the journey occupies two hours, while on the motor I can be home in thirty-five minutes.

The Petrol Committee replied they could give no opinion as to the reading of the Act.

I then applied to the City Head Constable, and he replied that as my journey lay through roads for the most part not under his supervision he would recommend me to apply to the County Constabulary.

This I did, and the reply was that if I had an up-to-date petrol licence I was at liberty to use my machine as indicated in the Act, and that it appeared I might be justified in using the machine as I proposed.

All this is about as clear as good, thick mud. What on earth has an up-to-date petrol licence got to do with it? I have the juice, obtained in a perfectly legitimate and above-board manner. Used as I propose to use it, it would last me six months. I do not want any more petrol—I have two gallons for starting purposes—and I do not propose to ask for any. I am proposing to use spirit obtained for pleasure purposes on business, but I have no intention of putting in an appearance before any magistrate if I can help it.

So where am I?

At present my motoring is confined to periodical visits to the shed to keep rust away, to oil up, and rub with vaseline, and give the handle an occasional turn—the machine is a 6 h.p. Enfield, and a jolly good machine, too—and then back into the house plus a lot of grease and dirt and a feeling that I have done a bit of motoring in spite of the Petrol Restriction Act, for I think the average motor cyclist is as happy overhauling his machine in the shed almost as he is watching the needle occasionally creep up to fifty on the open road, when there is no "bobby" looking. X.Y.Z.

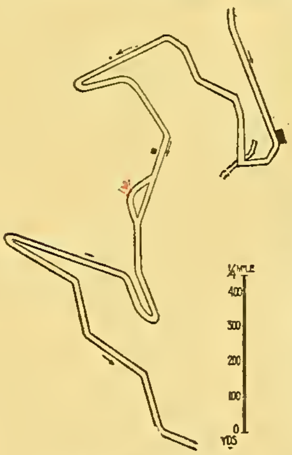
Liverpool.

[We think our correspondent will be quite justified in using his machine, but what individual magistrates will think is quite another matter. The case seems to hinge upon what may be considered as "reasonably convenient."—Ed.]

HAIRPIN BENDS.

Sir,—One hears a great deal of "hairpin bends" from riders in our road trials. I am sending you a plan of a road here in Palestine, which I have no doubt will be recognised by many lorry drivers and despatch riders who read the "Blue 'Un."

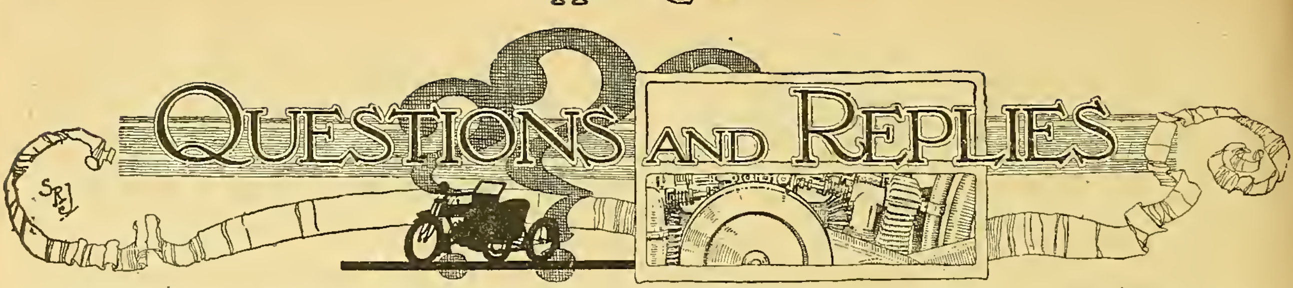
I wonder what some of the "old hands" would think if they had to tackle roads like this, consisting, as it does, of such bends, with a surface of metal about 4in. in diameter (unrolled) on a great part of it; also, nearly a sheer drop of several hundred feet if one gets over the edge (and there is no retaining wall if one should make a slip). Fortunately, accidents are rare, being prevented by having a "control" at the top and bottom, and traffic only allowed up or down at one time. If it would be of interest, I should be glad if you will kindly forward the plan to your sister journal, *The Autocar*.



Plan of a Palestine road.

I have the "Blue 'Un" sent me every week, and I feel sure that, in spite of the petty cavilling of one or two of your readers *re* your refusal to advertise German-made goods after the war, the good old *Motor Cycle* will still remain the dictionary of the motor cycling public.

Palestine. E. J. DAVIES (S.M., R.E.).



QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Dynamo Wiring.

I have a dynamo fitted with three terminals. (1.) Why are there three terminals on some big and small dynamos? (2.) Is one of them the shunt winding; if so, why is its connection not internal? (3.) How is it to be wired up?—E.B.

There are so many different types of dynamos that there may be practically any number of terminals, and the fitting of a terminal externally or internally is due simply to manufacturing considerations. We should advise you to write to the manufacturers of your dynamo, who will give you the information you require.

The Use of Petrol.

Would you be kind enough to tell me if permission could be got to drive a motor cycle from Saltburn to Stockton, on the grounds of a change of residence? As I have no licence, where should I apply?—J.W.P.

In the Motor Spirit (Consolidation) and Gas Restriction Order, 1918, under the heading "Necessary household affairs" for which petrol may be used, it is specifically stated that a motor vehicle may be driven in connection with "house removal." If you have petrol, therefore, no petrol permit is necessary, but if you have no petrol application should be made to the Petrol Controller's Department, 19, Berkeley Street, London, W.1.

Licences.

(1.) I have bought a second-hand motor cycle. Will you please tell me where to apply for a driver's licence and a registration number? (2.) Please tell me the conditions under which I can get petrol for testing purposes, and where to apply for the permit.—R.D.

(1.) For a driving licence you apply to the Clerk of your local County Council. If the machine has been previously registered, you may have the registration transferred to your name for 1s. by applying to the clerk of the county or borough council with which it was registered, or, if this registration has been cancelled, you may re-register it with any county or borough council in the United Kingdom. (2.) We do not think petrol will be granted to you for the purpose of testing the machine, but if you care to try you may apply to the Petrol Controller. In your application you should make quite clear why you need the petrol, and you will also have to produce your local taxation licence receipt.

Misfiring.

Would you be good enough to suggest a possible cure for misfiring in my 7-9 h.p. Indian motor cycle? The misfiring only occurs on opening up the throttle from a very small throttle opening; otherwise the engine pulls magnificently at speeds of thirty miles and over. I have tested the spark, and have found it to be satisfactory. I have also taken the carburetter down, and there appears to be nothing the matter with it. I have also cleaned the carbon brushes on the magneto, and can find no air leaks in the inlet domes or at the induction pipe unions. Closing the extra air shutter makes no difference to the misfiring.—P.J.C.

Owing to the bad petrol we are getting at the present time it would be advisable to open up the slots in the jet, and this will probably cure the misfiring of which you complain.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

Petrol for Naval Men on Leave.

Would you kindly let me know through the "Blue 'Un" whether Naval officers are allowed the small quantity of petrol which is allowed to Army officers whilst on leave? If I am allowed a little joy-ride, would you kindly let me know how and where to obtain permission to secure petrol for the purpose?—Ramsgate.

Naval officers are treated practically the same as military officers as regards petrol for use on leave, so long as this leave is not simply a few hours ashore. In order to save time, you should call personally at the Petrol Controller's office, 19, Berkeley Street, London, W.1. Your query breaks every rule under which we undertake to answer questions, and, but for the exceptional circumstances, we should be compelled to ignore it completely. Also the answer has been previously given in *The Motor Cycle.*

An Old Friend Again.

I use my sidecar for business purposes, which I explained when I made my application for petrol. Can I take my wife in the sidecar to see friends some forty miles from here?—A.J.

If your journey to visit friends would be undertaken solely for that purpose you cannot undertake it without incurring the risk of a fine. The presence or absence of a passenger in the sidecar would make no difference to the case.

Running on Paraffin.

(1.) What alterations would be necessary to the carburetter and engine of a 5 h.p. twin Indian to enable me to run on paraffin? (2.) What is the cause of "cutting out" when opening the throttle when running on the pilot jet? The engine stops for three or four yards. If I soldered up one or two of the holes in the main jet, would it be likely to prevent this from occurring?—E.J.Q.

(1.) The Indian carburetter is not suitable for use with paraffin. You can only make the engine run on paraffin by fitting a vaporiser to heat the fuel. The air should also be taken in warm, and the fuel should be heated by coiling the fuel pipe round one of the cylinder heads. In any case we do not think you will obtain very good results from the use of paraffin alone. (2.) The fact that the engine ceased to fire for a few yards may be due to many causes. When the throttle is opened suddenly there is a quick demand on the jet for more petrol, and any obstruction in the petrol supply pipe would cause the trouble. Again, the extra air lever may be too far open. If you soldered up any of the holes in the main jet it would probably make the matter worse. Do not interfere with the jet, but try the next size larger after verifying that all is clear.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns -First 12 words or less 1/6, and 3d. for every vo words after. Each paragraph is charged parately. Name and address must be counted. eries discounts, conditions, and special terms regular trade advertisers will be quoted on pplication.

Postal Orders sent in payment for advertisements should be made payable to LIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be ccompanied with remittance, and be addressed the offices of "The Motor Cycle," Hertford treet, Coventry. To ensure insertion letters hould be posted in time to reach the offices of The Motor Cycle," Coventry, or London (20, udor St., E.C.4), by the first post on Friday norning previous to the day of issue.

All letters relating to advertisements should uote the number which is printed at the end of ach advertisement, and the date of the issue n which it appeared.

The proprietors are not responsible for clerical r printers' errors, although every care is taken o avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☛ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

Motor Cycles and the Luxury Tax.

WE are not yet aware of what the Government intend in the matter of imposing a luxury tax upon motor cycles. If they follow the French model slavishly, motor cycles above a certain value will be classed as luxuries. At the present time it can be asserted without much fear of contradiction that no motor cycle is a luxury. Such machines as are still on the road—and they are indeed few—are necessities pure and simple, run by their owners either in the national service or for strictly business purposes. They would not be allowed on the road at all, except under these conditions.

As, however, we assume that the luxury tax will remain in force for some little time after the war, and possibly after the resumption of recreative motoring, it may not be inappropriate to consider the position of the motor cycle with regard to this tax. Already the motor cycle is the most highly taxed vehicle on the road having due regard to its size and weight. If a rider has a new machine every year his taxes are as follow: Local taxation, £1; driving licence, 5s.; registration, 5s.; to this may be added petrol tax at 1s. per gallon, making a total of, say, £3 per annum. The owner of a horse and trap pays only one-quarter of this amount, occupies much more of the road, and does considerably more damage. It may be urged that a motor bicycle, with its greater speed, travels a greater distance in the course of a year than a horse and trap. This may have been the case before the war, but with the present petrol allowance (usually half a gallon a week) it is quite possible that it is not true at the present time, and, owing to the greater speed of the motor cycle, it is probable that, even if the horse and trap does not travel quite so far, it is longer on the road.

We hope that the French model to which we have referred will not be followed too closely, for it contains many absurdities, *e.g.*, feathers are untaxed up to the value of 20s.; school books are taxed no matter what the value. Any schoolboy can say which is the greater luxury.

A Petrol Control Department Anomaly.

AS is generally well known, the Petrol Controller's Department grant short-time licences to soldiers and sailors on leave from Overseas. These licences are granted to all owners of motor cycles, or to those who can borrow machines from members of their families.

Recently a case came to our notice of a soldier to whom leave was due applying to the Petrol Controller's Department for petrol to run his father's motor bicycle during his leave. In accordance with the regulations, he sent up the registered number, and on the case being investigated by the Department it was found that the father had already a petrol licence. Now, it was the inflexible rule of the Petrol Controller's Department not to grant two licences in one family, consequently the soldier's application was refused, although it was pointed out to the Department that the case seemed to be a very hard one. It seems an injustice and a typical instance of Government red tape that this soldier, who was looking forward to the use of a machine during his leave, should be prevented from enjoying a little well-earned recreation simply because there happens to be already a petrol licence in his family.

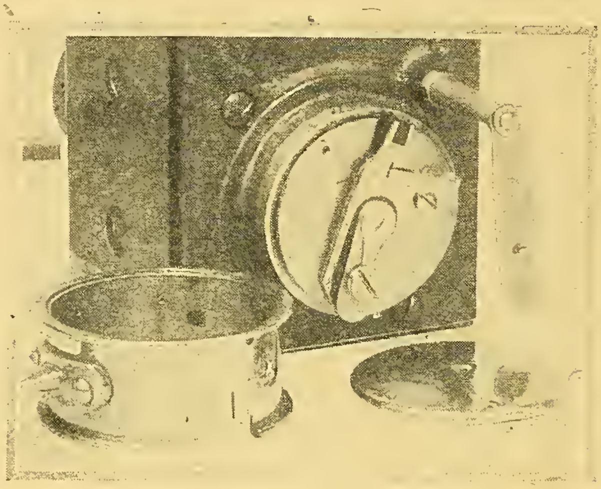
It is perfectly obvious that the licence is granted to his father for strictly business purposes, and it is clear that the two gallons a month which he receives is only sufficient for the particular purpose for which it is allotted, and that there will be none left for the soldier son when he comes home. The matter of a few gallons of petrol is of so little importance and yet can involve so much hardship that we should think that the Petrol Department might well reconsider the matter.

An index to the advertisements in this issue will be found on the page facing the back cover

A HIGH-SPEED CONTACT BREAKER.

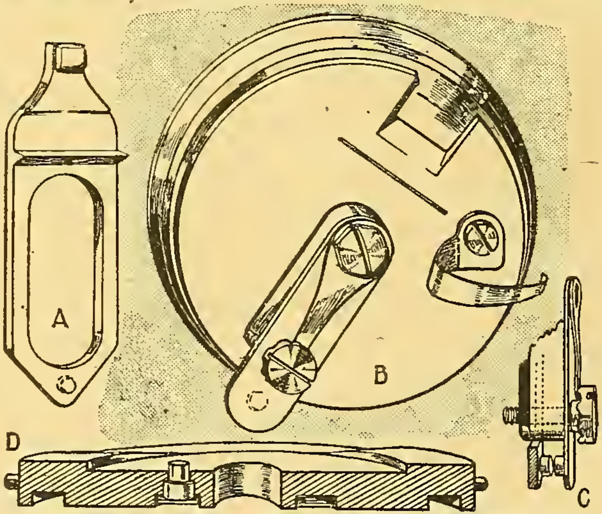
A CLEVER DESIGN OF REMARKABLE SIMPLICITY.

THE development of the magneto contact breaker has progressed considerably in the direction of high speed make and break, and one hears rumours of wonderful magnetos which will give an astonishing number of sparks per minute, but many makers under Government control find development somewhat hindered by the slavish adherence to Bosch designs in Government specifications.



The Payne contact breaker with cover removed.

Mr. Alex F. Payne, of 149, Metchley Lane, Harborne, Birmingham, is an inventor who has departed from the customary pattern, and has produced a contact breaker which is simplicity itself. It has a minimum of moving parts in which friction is almost absent, and its sparking capacity is only limited by electrical considerations in the magneto itself. A light rocker arm, carrying the fibre wipe on one end and one platinum point at the other, lies across a face plate, and a knife edge resting in a groove gives the fulcrum for the necessary movement. The face cam on the fixed plate behind the contact breaker opens the points, and a light spring operating on the rocker arm close to the fulcrum closes them. The total movement is almost imperceptible.



A. The rocker arm, carrying platinum point and fibre block. Note the knife-edged fulcrum.
B. Contact breaker, with rocker arm removed.
C. Adjustment of platinum points.
D. Section through cam plate showing fitting of carbon brush.

The inventor makes a particular point of the accessibility and ease of adjustment. We have the magneto before us, and have dismounted and reassembled the whole contact breaker in less than one minute, using only a penknife. The points can be adjusted by turning a screw head with a screwdriver or knife blade, and serrations on the underside in conjunction with a light spring prevent any slipping out of adjustment. The rocker arm can be detached and replaced with the fingers so easily that its removal might be recommended as a good method of preventing theft when the motor cycle is left unattended. The rocker arm balance is so carefully arranged that a very light spring is all that is needed, and the weight of the arm is so distributed that centrifugal force helps to close the points.

Such a simple design should be capable of make and break at almost any speed. The limit of test so far is 6,000 revs. per minute—a very high speed for a single-cylinder magneto. It has stood the test well—in fact, it is almost certain that the only limit to its sparking capacity is when the high speed distorts the lines of magnetic force to such an extent that the primary circuit is not broken.

It speaks well for its wearing qualities that the model before us has completed over seven million revs. on test at high speed without any appreciable sign of wear. This type of make and break has the particular advantage that it runs equally well in either direction.

There are several other new ideas incorporated in this model, notably the fitting of the carbon brush in the front of the cam plate instead of in the usual place at the back of the contact breaker.

Mr. Payne has fully protected his ideas, and the patents embody numerous alternative methods, including application to an internal cam of the usual Bosch type. Several well-known firms have given it favourable consideration, and have tested it to their own satisfaction, but the departure from the accepted Bosch type seems to be the chief stumbling block in the way of its development on a larger scale at present. We must congratulate the inventor on the excellent workmanship of his experimental models. He will be glad to supply models for test to any firms who may be interested.

The Petrol Control Department has issued a new Order which permits licensed motor cabs, *i.e.*, taxicabs, to be driven outside the areas hitherto sanctioned for their employment, provided that the class of journey comes within certain categories. The concession applies to journeys undertaken on any urgent necessity where life or limb is, or may be, endangered; for the conveyance of a sick or injured person to a place where he may receive treatment, or to or from a nursing home; or for visiting a person who is dangerously ill.

Occasional Comments by "Ixion"

Huns Use V Engines?

I ASKED the other week for some information about the type of bicycle used by the Hun D.R.'s. Advices to hand are extremely scanty, but indicate that both for despatch riding and light machine gun units Fritz relies on a very heavy machine with a V twin-cylinder engine. It is probable that two makes are used, of which one is the N.S.U. When sufficient time has elapsed for my enquiry to reach the Palestine Front, we may get further details.

Difficult Starting.

I READ with considerable interest the Rev. W. F. A. Ellison's wrinkles for kick-starting a B.S.A. His methods obviously suit the B.S.A., or he would not be so enthusiastic about them: but they do not necessarily suit other machines, and therefore they are not given as standard practice in the "books," which he denounces for the omission. Considering the "cold start" first, he injects petrol, puts the piston just over the T.D.C. of the compression stroke, and then gives a mighty kick. This dodge suits the B.S.A., because it is an awkward engine to get spinning when it is cold, and because its carburetter will give a good puff of rich mixture. Many engines can be kicked round fast without this careful setting of the starter: and lots of carburetters are so adjusted that the jet does not readily furnish a good starting mixture, so that it is not wise with them to "exhaust the dope," as our correspondent does with his B.S.A. In other words, the meticulousness of his starter setting is a waste of time with some engines, and the consequent scavenging away of the petrol injection would actually destroy the hope of a start with certain carburetter adjustments.

Starting from Hot.

SIMILARLY, Mr. Ellison's hot starting methods are by no means of universal application. He suggests that, if the ignition and valves are in perfect order, faulty mixture must be responsible for any difficulty, and that riders often spoil the mixture by leaving the air lever shut, as they would for a cold start: that since the perfect mixtures for cold and hot engines are not identical, the air lever positions for cold and hot starts are not similar: the lever should be shut for a cold start, and a little way open for a hot start. This reasoning is plausible, and applies to some engines and carburetters: but it is not invariably sound.

For example, it is not true that the air lever should always be shut for a cold start: there are many machines on the road which like a fractional air opening. Again, when an engine is getting out of tune, the chief trouble about a hot start often consists not in a faulty mixture, but in the almost total absence of any mixture at all. The compression is very leaky, so that, when the engine is hot, hardly any suction is exerted on the jet with the piston moving at the speeds obtainable by operating the kick-starter; but when such an engine is cold, the compression leaks are partially sealed by gummy oil, and a better suck will be obtained. Under such circumstances, the air lever must be shut for a hot start, so that all available suction may be concentrated on the jet. Indeed, if the compression leaks existed solely at the piston rings, and not at the valves, it is conceivable that an engine might only start cold with the air lever open, and refuse to start when hot unless the air lever were shut—the exact opposite of Mr. Ellison's procedure.

Know your Machine.

THESE considerations explain why the starting methods recommended by Mr. Ellison and other "one machine" enthusiasts do not figure verbatim in *standardised* instruction books, written to cover all makes of engine and carburetter. One might say that starting methods vary according to at least five factors, viz.:

1. The make of the engine.
2. The tune of the engine.
3. The make of the carburetter.
4. The adjustment of the carburetter.
5. The leverage of the starting mechanism.

Even this formidable catalogue omits gear boxes of special design, which import additional complications; magnetos disfigured by a peculiarly weak slow-speed spark, etc., etc.

On the other hand, Mr. Ellison may well ask why *manufacturers'* handbooks fail to provide all the necessary information about proprietary machines. In this case, where one set of instructions could cover all imaginable situations, I suppose one of two explanations is true. Either the manufacturers deliberately simplify their instructions, in order to avoid confusing the minds of novices: or else the literary staff are not practical men in close touch with the running shed.

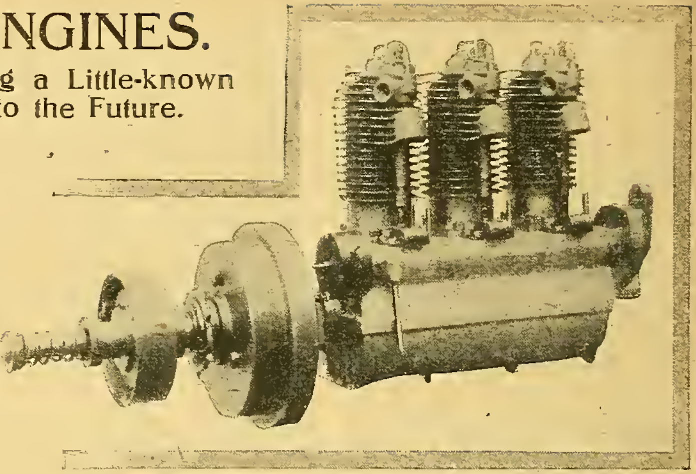
The makers should certainly supply an elementary handbook for novices, and this should be as simple as possible. It should be supplemented by more advanced booklets of hints and tips, such as those the Rudge and Triumph firms used to issue for advanced and studious owners.

Articulated Connecting Rods.

AS the Hun has long been aware, aero engines of the V type usually scorn the typical motor cycling method of linking up connecting rods. A popular pre-war design mounted the single rod so as to oscillate on the outside of a bush fixed in the ends of the forked rod. It has two chief defects. The area of the bearing was never excessive, and in repair work fitters had to be tolerably skilful if both the inside and outside of a single bush were to be true. In many V aero engines the single rod works on an auxiliary pin of its own fixed in housings provided on the outside of the main big end bush. Will this practice be imitated in post-war motor bicycle engines?

THREE-CYLINDER ENGINES.

Some Commentary Remarks concerning a Little-known Type of Engine, and a Peep into the Future.



A three-cylinder 8 h.p. J.A.P. engine, manufactured more than twelve years ago.

ALTHOUGH, on the point of balance, the single-cylinder engine, theoretically, is the worst type of all, it is perhaps the most popular. This goes to show that theory and practice do not always go hand in hand. It is, however, fairly safe to consider that the thing which is theoretically perfect will become recognised as superior in practice eventually.

In the car world the single-cylinder engine has disappeared entirely. Even in cheap, simple cycle cars a single-cylinder engine would hardly be accepted *at any price;* therefore one can say that the single-cylinder engine is being frozen out of the world of motor cycle mechanics. In the immediate future we shall have this type of engine for solo and medium-powered sidecar machines, but *the* sidecar machine will be one having more cylinders than one. At least, such is the opinion of the writer. Having reached this point, one considers which type of multi-cylinder engine will be most favoured in the future: the type which will emerge from the experiences gained with all types as the one embodying all their best points.

Will the V twin retain its popularity? I do not think so. If it does, it will be a very different type of V engine from that so popular at the present time. An ordinary V engine is really little more than a single with another cylinder added to the crank case. Each cylinder has not mechanism to do its work separately on the crankshaft. It can be likened, almost, to a river with two sources, the junction coming at the "big end" bearings.

Simplicity in Design.

It is, of course, a simple way to construct an engine, and simplicity is a virtue in motor cycle design, although designers who make a fetish of engine efficiency, and ignore the points which go to make up general or overall efficiency, may not always be satisfied to make simplicity the keynote of design, and eventually engine efficiency and general efficiency must make common cause and run in parallel lines. The perfect V undoubtedly will be the 90° type with a properly balanced crankshaft and outside flywheel. But supposing shaft transmission comes along as the "standard" transmission? There is no reason to suppose that it will not. Cars have passed through the same stages in development as the motor cycle may—belts, chains, and shafts. In engines, too, the car first had singles, then twins, then four and six-cylinder engines.

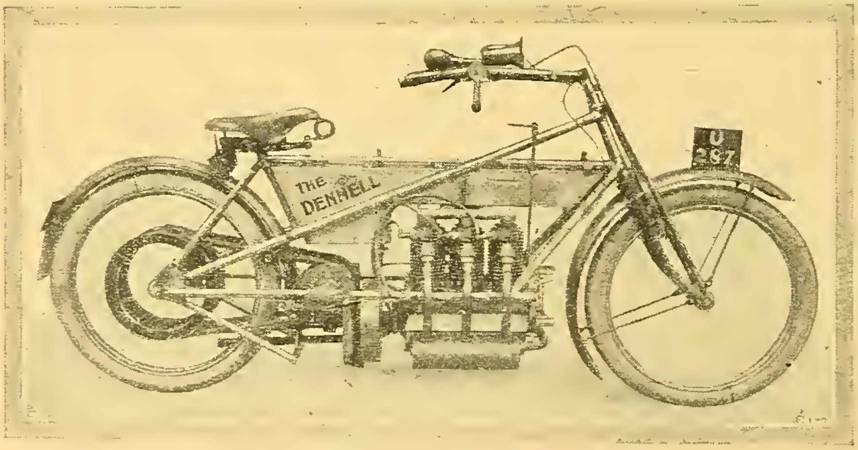
The Ideal Power Unit.

Arguing along these lines, one may say that the four-cylinder engine eventually will be the type for motor cycles, with perhaps a "six" as super de luxe models for munition millionaires. At present, however, one cannot expect a great deal of power from any cylinder much below 250 c.c., hence a four-cylinder machine will be about 1,000 c.c. total capacity, which, considering that engines of this size have proved to be sufficiently powerful for light cars, appears to be too large for the average sidecar machine. An engine with a total capacity of about 700 to 750 c.c. probably will be the "ideal" size for passenger work, but, when one considers cylinders of 200 c.c. or less, the "four" does not appear to be the type of the future.

It has been proved that 250 c.c. per cylinder in a "four" is quite good. Then why not have three cylinders of this size?

Looking upon the V twin as a makeshift, the vertical twin out of it on account of its bad impulse torque, and the "four" because it is too large, a three-cylinder engine of the vertical type undoubtedly offers many advantages for careful consideration. The balance is good —in some respects superior to a "four"—and the firing is at equal intervals.

It may be remembered by some of the older readers of *The Motor Cycle* that a motor cycle with a three-cylinder engine was made in Leeds early in 1906. This was the



The Dennell motor cycle of 1906 fitted with a three-cylinder J.A.P. engine.

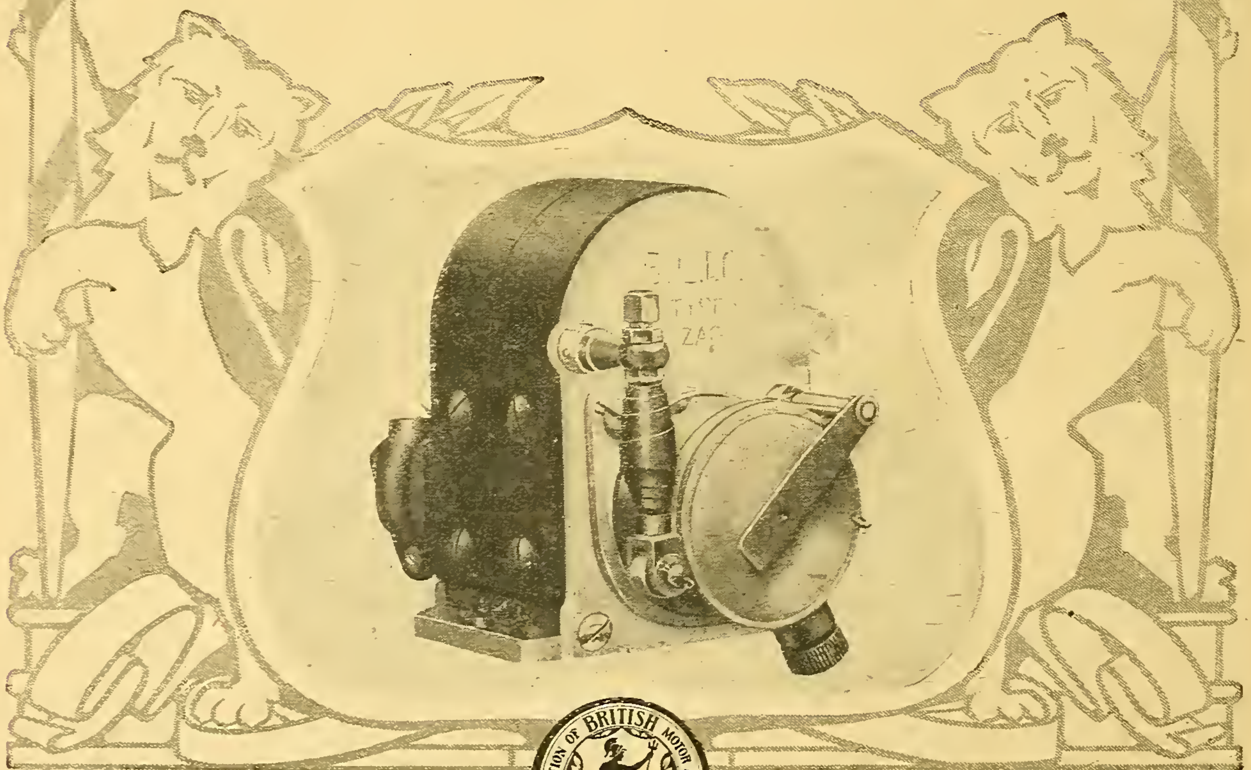
B·L·I·C

The British-built Magneto with a record behind it.

RENOWNED for Reliability and Efficiency, its performances under war conditions have served to perfect the sterling qualities of the "B.L.I.C." MAGNETO, and to-day it stands supreme amongst magnetos—whether British or foreign.



British Motor and Allied Manufacturers' Association

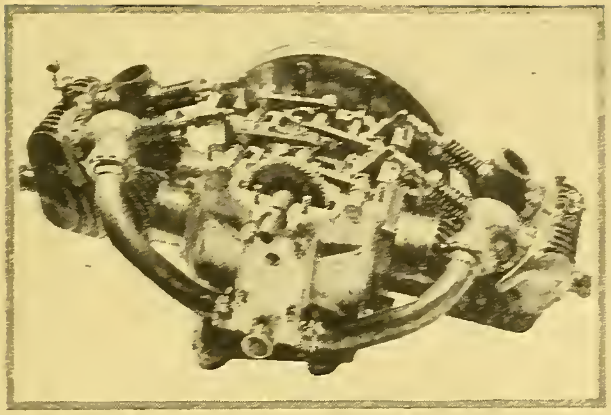
THE BRITISH LIGHTING AND IGNITION CO., Ltd.,

204, Tottenham Court Road,
London, W.1.
Proprietors - VICKERS, LIMITED.

In answering this advertisement it is desirable to mention "The Motor Cycle."

Three-cylinder Engines.—

Dennell, which is illustrated here. The Jowett light car concern also experimented with an engine of the kind, while Messrs. J. A. Prestwich marketed a vertical "three" for cars or cycles. In the car world, there were several cars fitted with three-cylinder vertical engines.



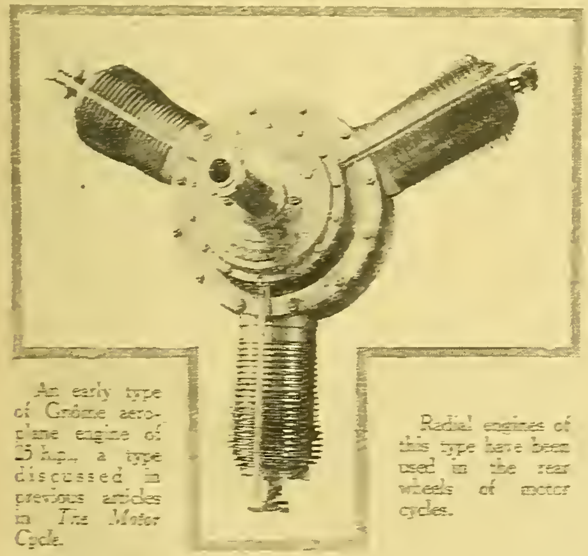
A paradox in steel—the Humber three-cylinder twin. Two small cylinders with common combustion heads oppose a single-cylinder of approximately twice the capacity.

There are other types of three-cylinder engine; in fact, about ten years ago there appeared promise of a three-cylinder boom in the French industry, while, it may be remembered, the Humber Company produced a three-cylinder opposed engine of a very unique design.

Most of these, however, may not again become popular, although one can never be sure. The great interest in aeronautical matters at the present time may lead to radial three-cylinder engines for both motor cycles and small cars.

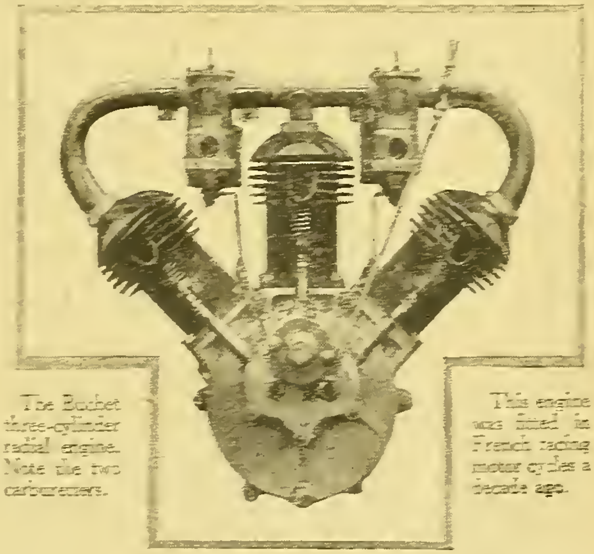
For a sidecar machine, however, I think in the three-cylinder vertical engine we have a type which is more than a compromise between the twin and the "four," and if shaft transmission finally takes the place of belts and chains, undoubtedly it will receive serious consideration on the part of designers who wish to produce lighter and more economical machines than the smallest practicable "four," and smoother running than is obtainable with any four-stroke twin which would be suitable for use with shaft transmission.

VELETTE.



An early type of Gnôme aeroplane engine of 25 h.p., a type discussed in previous articles in *The Motor Cycle*.

Radial engines of this type have been used in the rear wheels of motor cycles.



The Buchet three-cylinder radial engine. Note the two carburetters.

This engine was fitted in French racing motor cycles a decade ago.

The Automobile Association Coal Gas Prize.

Progress of Entries for the £1,000 Prize.

MANY entries have been received for the A.A. competition, particulars of which we announced some time ago. Apparently the competition has not brought in only half-thought-out schemes, as it must be admitted many people expected it would, and many valuable suggestions have been received.

A most important incidental result of the competition has been the stimulation of research and investigation into the possibility of using other fuels besides coal gas, petrol, and petrol substitutes, while the important question of adequate supplies of coal gas and benzole for post-war requirements has received a much-needed impetus.

The competitors have come from all classes, including engineers, gas experts, private motorists, and mechanics, and it is significant of the new spirit animating the motoring community that experts on the fuel matters under consideration have expressed their willingness to investigate and bring the promising ideas of non-experts to a practical stage. Without expecting too much from the results, we hope real benefits will ensue.

Entries for the competition close on December 31st, 1918. Copies of the entry forms and the conditions governing the competition will be sent on application to the Secretary, A.A. and M.U., Fanum House, Whitcomb Street, London, W.C.2.

Charity.

The handsome donation of £520 has been handed over to the Coventry and North Warwickshire Hospital as the result of the sports meetings, which were recently held under the auspices of Humber, Ltd., Coventry, on the Humber Recreation Ground.

Imports and Exports.

The value of imported motor cycle parts and accessories for May amounted to £586.

There is a decrease in the exports as against last month, and also against the corresponding month of 1917.

	1916	1917	1918
Motor cycles, parts, and accessories	79,866	60,850	48,861

The export figures for motor cars and parts are extraordinarily high for the month of May. The amount is £1,469,228, as against £210,658 for the corresponding month in 1917.

The Privileged Classes.

According to a correspondent, a Woolwich A.S.E. engineer, during the Whitsuntide holiday, rode 200 miles on his motor cycle without being questioned. Why are we all not engineers?

The Rand M.C.C.

At a committee meeting of the Rand M.C.C. some interesting resolutions were passed. It has been decided to discontinue all competitions and to concentrate on social runs in connection with the war funds or convalescent work. Further, the committee is going to bar "eligibles" from what may be called active club life.

Goods made in Germany.

Most of our readers will remember that a few months ago a lively discussion on our notice on this subject was carried on through our columns. A further step in the direction of the boycott of German goods has been recently proposed by the proprietor of an important Midland hotel. He asks everyone in control of hotels in Great Britain not to house any alien enemy, as such a step as this would make it extremely difficult for "these brutes to conduct their business as in pre-war times." The suggestion has the support of General Page Croft, M.P., who recommends all who agree with it to write to 22, King Street, London, S.W.1, for a National Boycott pledge.

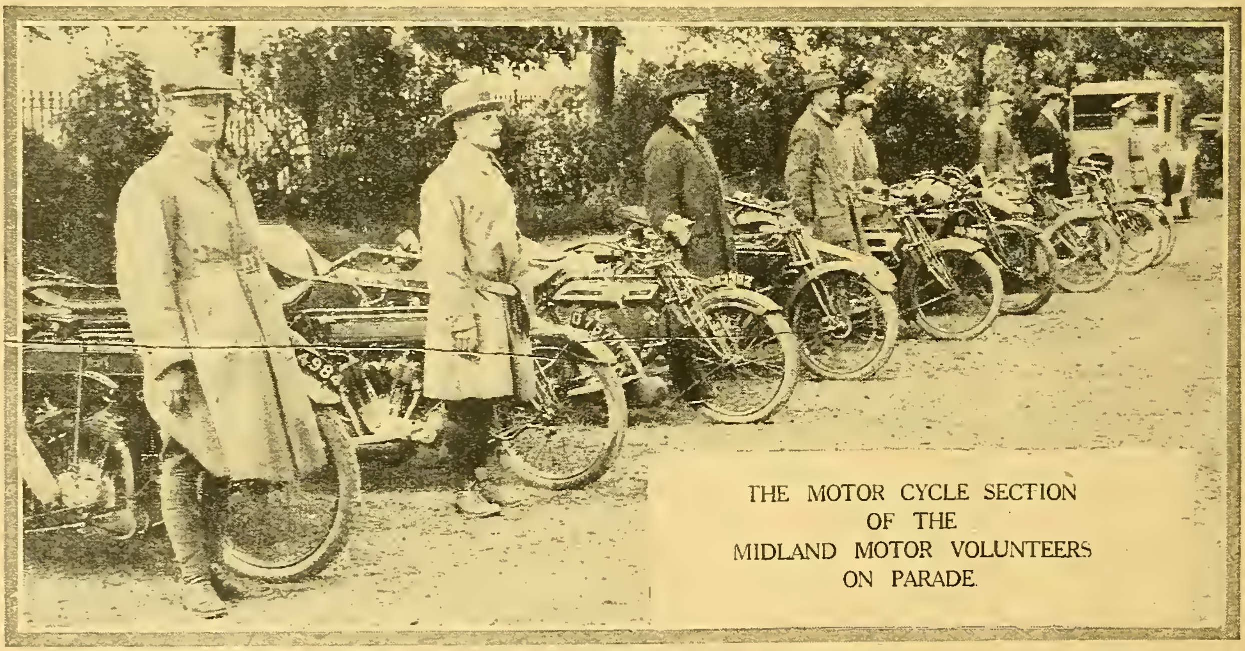
Larger Tyres or Spring Frames.

The increased comfort with oversize tyres is well worth the extra cost and weight. At one time a well-known competitions timekeeper used to ride a 2¾ h.p. Bat with a 3in. back tyre, and the comforts obtained with this softly inflated were most gratifying. With the roads in the condition in which they are likely to be immediately after the war, it may be anticipated that those firms who do not fit spring frames will consider the question of fitting larger tyres. Many have already decided to do so.

Tyre Repairs!

We take the following from the *Cape Times* of May 3rd, and refrain from comment:

"A Johannesburg motorist was hung up last Sunday on a lonely part of the road with a punctured back wheel, no repair outfit, and no spare tyre. The few cars that passed could afford no assistance, and the only shop within hail was the usual Greek fruiterer's. In an access of optimism (or desperation) the stranded motorist bought a shillingsworth of chewing gum—Chicelets, to be precise—and masticating three of the little tablets he pressed the result over the hole in the tube. This 'repair' took him all the way from Boksburg to Johannesburg, and the tyre was even standing up the next morning."



Motor cyclists on parade at the Midland Motor Volunteer Mobilisation Test last week. The machines shown in the photograph are the James, Enfield, Rover, A.J.S., and Rudge.

Police Trappers join up.

The latest draft of Metropolitan police to join up include two of the best known trappers in South London.

Alcohol.

What is being done to convince an obstinate Government that it is necessary for the absurd restrictions regarding alcohol fuels to be amended?

Capt. Vernon Busby.

Capt. Vernon Busby's father writes us stating that his son was not mobilised, but travelled all night to reach Birmingham to enlist on August 6th, 1914, and went to France four days later.

Spring Frames.

"It is virtually certain that after the war there will be put on the market not one but several spring frames that will meet the requirements of users in this country and overseas."—*Bicycling News.*

A New Model.

Most of those in the know in motor cycling matters think that the flat twin will be the solo engine of the future, and there is no doubt that one of *the* flat twins will be the new model Brough. This, which exists complete only on paper, but of which the engine has undergone very thorough bench tests, is one of the most fascinating and well-thought-out designs we have seen. The utmost care is evident in the working out of every detail; even the frame lugs are tapered so as to prevent unsightly corners where they join the tubes, while the engine is now carried in a duplex frame cradle, which is detachable, so that the whole power unit may be removed *in situ* with its supporting tubes.

Equipment.

Signs are not wanting that our suggestions on the turning out of machines complete with equipment are meeting with approval. The new Brough model, for instance, is to incorporate a Lucas dynamo lighting set as standard, the set being an entirely new one designed primarily for use on solo machines. The new Brough also uses 28in. × 3in. tyres (but the height of the saddle is only 29½in. from the ground), an internal expanding rear brake and a front brake of the Lea-Francis type, and a special steering head and front fork adjustment.

Induction Pipe Design.

We have on several recent occasions indicated the necessity for some form of induction pipe heating on post-war machines. In the new model Brough this matter is fully looked after, and the design adopted should prove most efficient, for heat is obtained both from the cylinders and from the crank case.

Another interesting little detail about this striking machine is that the solid crankshaft has ⅝in. square roller bearings, and all ring has been eliminated from the outside flywheel—a bugbear that many makers have unsuccessfully fought against.

Power.

The new Brough engine, though only of 500 c.c., gives 14 h.p. at 4,200 r.p.m., and has attained the extraordinary speed of 5,600 r.p.m., the power output at this speed being 13.2 h.p.

Petrol at Atlantic Ports.

Petrol costs the Allies 11¾d. per gallon at Atlantic ports.

The T.T. Red Flag.

"Arguing that alcohol has long been the stormy petrel of politics, a correspondent of the *Licensed Victuallers' Gazette* considers that the possibilities of ensuring a home-produced motor fuel might be increased were alcohol to be called benzoated hydrocarbon or B.C.H. Although the suggestion is made somewhat facetiously, there may be something in it!"—*The Autocar.*

Capital, Labour, and the Millennium.

We have already referred to those innumerable committees working with the excellent end in view of ensuring the millennium for us all after the war. One of these committees has now come forward with several rather sensible suggestions, the underlying point of which is that the Government should only take action in commercial matters after consulting a joint body representative of both employers and workpeople. As this committee points out, any Orders issued by the Government on the joint advice of both parties should be likely to find general acceptance. Whether the actuality will work out to the ideality is a matter that only test can prove, but all these schemes and their promoters deserve at least a fair trial.

As the present is such an ideal time for experimenting with all kinds of schemes, it is suggested that the following policy should be immediately adopted: "That the Government will undertake to obtain, and wherever possible accept, advice on these matters from bodies equally representative of both labour and capital."

New President and Vice-presidents of the S.M.M.T.

Mr. Albert Brown, of Messrs. Brown Bros., Ltd., has been elected president of the Society of Motor Manufacturers and Traders, and Messrs. Frank Lanchester and T. H. Woollen have been appointed vice-presidents.

The Indian Flat Twin Lightweight.

Elmer Bergstrom, on an Indian light twin, created a new record on May 23rd this year by riding 799 miles in twenty-four hours on the Tacoma Speedway, and would have done better but for a fog that compelled him to cut down his speed to the safety margin during the night.

To run on Paraffin.

Anticipating a potential demand for a sidecar combination that will run on paraffin, a designer in the Midlands is designing a special engine for this purpose. It is larger, heavier, and has a lower compression ratio than the conventional type of engine.

American Motor Cycle Scrap.

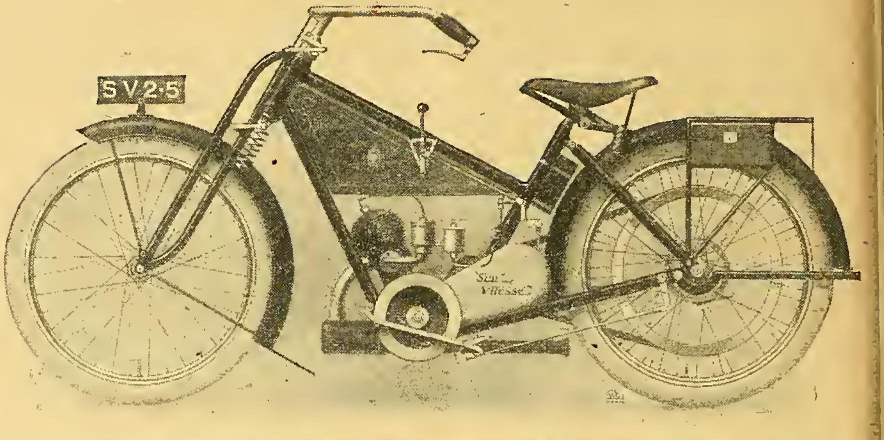
It may be remembered that last summer we had an interesting article in this journal describing the accumulation of motor cycle scrap resulting from the hard work British Army motor cycles have had to undergo behind the British lines. The same thing is happening to the American machines. In a recent copy of an American journal which has reached us there is a photograph of a group of Indian sidecars smashed during service with the American forces in France. There is evidence that these machines are being overhauled and restored in the same efficient manner as our own.

THE MOTOR CYCLE AS HAY CART.

Mr. Prothero asks that the grass that grows on the country wayside should be gathered. Parties of men have now been organised to gather the grass on Sundays, and the photograph shows a 4 h.p. Bradbury carrying the grass to the rick yard.

THE POST-WAR SUN-VITESSE TWO-STROKE.

An Entirely New Lightweight embodying many Striking Departures from Accepted Practice.



This new model, with an inclined engine unit, is quite distinctive from former Sun machines. The two-speed gear box mounted above the chain stays gives an almost straight line of drive.

NEW models are few and far between in these days; there is therefore added interest in the new lightweight which is to form one of the chief items in the after-the-war programme of the Sun Cycle Co., of Aston Brook Street, Birmingham. This firm, in conjunction with the makers of the Vitesse engine unit, have gained a reputation for sound work in past years, and their lightweight should give much satisfaction.

They have effected a complete redesign, and the result is a mount of appearance altogether different from that of the former Sun-Vitesse models. Primarily, it is intended to be produced at a remarkably low figure. One model only is to serve for riders of both sexes, and simplicity throughout is the chief feature.

The designer of this model is Mr. J. Duffy, manager of the Valveless Two-stroke Engine Co., Ltd., Broad Street, Birmingham, who has had a long experience with two-stroke machines. He holds that there is still much to be learned regarding the simple two-stroke engine, and he believes that most of the usual faults can be eliminated by careful design and the study of various points, such as the ratio of crank case compression to cylinder compression.

The frame is a type of loop complete in itself; that is to say, its strength is unaffected, whether the engine is in place or not.

The Power Unit.

The cylinder is of usual construction, except in one or two minor details, but it is inclined forward at about 27° to the vertical. The crank case bolts solidly into the frame lugs without bearer plates. It has a one-piece aluminium casing having a bearing on one side only—a well-tried method which is perfectly satisfactory. The bearing is of considerable length, plain phosphor-bronze bushed for most of its length, with a ball bearing on the inner end. The other side of the crank case consists of a movable cover plate held in place by five bolts. When this is removed and the cylinder lifted, the whole shaft, big end, connecting rod, and piston can be dismantled without shifting the crank case. The shaft has a small cover stud screwed into the unsupported end. The big end has a plain bearing; the gudgeon pin is fixed in the little end by a cotter pin, and takes its bearing in the piston.

Magneto Drive and Transmission.

It will be seen that all these constructional details make for simplicity and reduction in the cost of manufacture.

The chain drive to the countershaft is utilised to drive the magneto—a method which will require much testing before an opinion can be definitely given upon it—but provision is made for a separate drive without altering the design, should the combined drive prove unsatisfactory. The magneto is mounted in an unusual position to obtain this combined drive; it is enclosed in a lug inserted in the down tube, with a hinged clamp over it to facilitate removal.

The gear box is mounted above the frame with the idea of providing as straight a line of drive as possible from the engine-shaft through the countershaft to the back wheel.

This model is designed to allow of easy conversion from single-speed to two-speed, the fitting of the gear box and magneto drive being a simple matter, without alteration to the general build. In the two-speed model, the driving chain is enclosed in a neat aluminium cover.

The type of gear box has not yet been decided upon, but in all probability a special gear will be made for this particular model. The carburetter is a complete departure from the usual practice. We are not permitted to disclose its details, but it has given extremely satisfactory results for some time past, and it may be destined to play an important part in the elimination of much of the trouble to which two-strokes are prone.

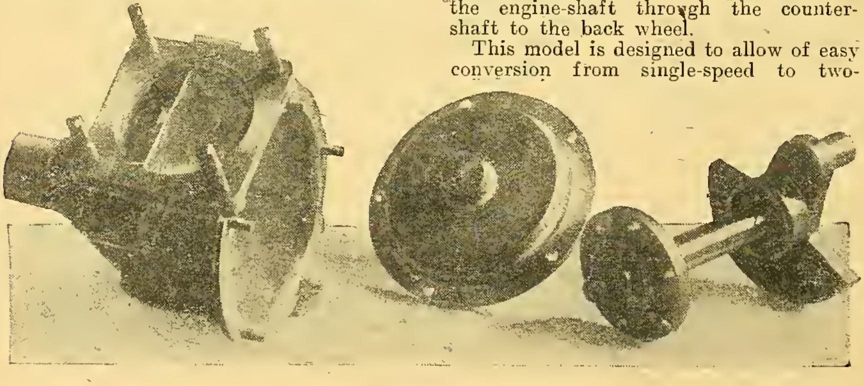
The unusual frame design gives room for a large tank holding nearly two gallons; a separate oil tank is fitted under the saddle on the down tube. Lubrication is by drip feed in the usual way, with one lead to the cylinder wall. After being used there the oil drops into a small reservoir formed in the crank case casting, from which oilways are drilled to the main shaft bearing. A drain plug is fitted to the crank case sump.

The front forks are simplified, and consist of two tubes of similar shape on each side, a point which aids manufacture and lessens the cost. Aluminium footboards and front and back brakes of the internal expanding type are provided, the back brake being operated by a left heel lever and the front by Bowden cable from the handle-bars.

Price and Production.

There are many points in this new model which may prove distinct advances on previous two-stroke design, and the Sun Co. are hoping to produce it in large quantities when the motor cycle world comes into its own again. It is early to talk of prices, as the future cost of materials and labour is quite impossible to estimate at present, but if the cost of production returns to something approaching the pre-war basis, the price of a single-speed model is likely to be nearer £20 than £30, and the two-speed model about £5 or £6 more.

Such a promising design should certainly form a distinct forward step in the progress and popularity of the post-war two-stroke lightweight.



The crank case with cover removed. Note the small oil reservoir above the shaft bearing. The shaft is shown with the boss of the outside flywheel attached.

THE MOTOR CYCLE AVIATION SECTION

The First Airship.

Giffard, a Frenchman, constructed an airship driven by a 5 h.p. steam engine in 1852.

R.A.E.

Probably few people know that the huge aircraft factory, which up to April last was always known as the R.A.F., is no longer so named, but has been officially rechristened R.A.E.—Royal Aircraft Establishment—presumably to distinguish it from R.A.F. (Royal Air Force).

The King.

The King recently visited one of the large aircraft repair depots, Royal Air Force, in England. During his tour of inspection to the Motor Transport Repair Section, His Majesty made a special point of visiting the motor cycle repair shops, in which he showed a keen interest, spending some little time chatting with several of the mechanics.

Royal Air Force Decorations.

It is officially announced that the colours of the ribbons of the new R.A.F. decorations and medals are as follow:

Distinguished Flying Cross, purple and white.

Air Force Cross, red and white.

Distinguished Flying Medal, purple and white.

Air Force Medal, red and white.

The ribbon will in all cases be worn so as to show a coloured band at the top.

One Thousand Horse-power Bombing Machine.

The four-engined German bombing machine which was brought down by the French near to Nanteuil-le-Haudouin is a copy of a Russian model with which experimental flights were made before the war. The following particulars of the reconstituted machine appeared in a recent number of our French contemporary *L'Auto:*

The motive power consists of four six-cylinder water-cooled engines of 260 h.p., two driving screws of the pusher type, and two driving screws of the tractor type. The armament comprises four machine guns—two mounted forward and two aft—and the bombs carried weighed three tons. In flight order, for a journey of five hours at a speed of about 70 m.p.h., the total weight with 660 gallons of petrol and a crew of eight is 15 tons. The crew is composed of a captain, an observer, two pilots (with connected control), a wireless operator, and four gunner-mechanics. The body is divided into two compartments, communicating by means of a side passage.

Hun Slang.

The German flying men called an aeroplane a "box," as compared with our word "'bus." A big bomber is an "apple barge." The body of the machine is the "shop window." An alternative slang term for the machine is "packing case" (many German planes have fuselages cowled and faired with plywood). Bombs are "liver sausages" or "eggs."

Hun Raids on Hospitals.

The recent Hun bomb and machine gun attacks on our hospitals in France form yet another example of his ruthless logic in warfare and his absolute contempt for his own plighted word. Our hospital system in France was enlarged, partly to counter his torpedo attacks on hospital ships and partly to save tonnage. His raids on Etaples and other Red Cross centres are simply designed to force us to use tonnage in transporting our wounded, or, alternatively to hamper the French railways. Before long he will realise that the new policy appals the few remaining neutrals, and he will then produce some plausible yarn that we use the Red Cross to protect our base dumps of ammunition, etc.

Stampeding the Transport.

According to recent information, one of the most successful dodges for pilots who are sent to raid enemy communications in daylight takes the form of ignoring the infantry in a marching column and stampeding the transport. A few well-placed bullets or a single, small, deftly aimed bomb may stampede a team of horses harnessed to a heavy waggon.

A Pitfall for Tyros.

The embryo pilot does not easily grow accustomed to putting his joystick back in neutral after a momentary correction of his "trim." It is rather difficult to explain this subconscious trick, as motorists naturally straighten out their steering after a divergence. Possibly the cause is that the joystick reminds the beginner of a gear lever.

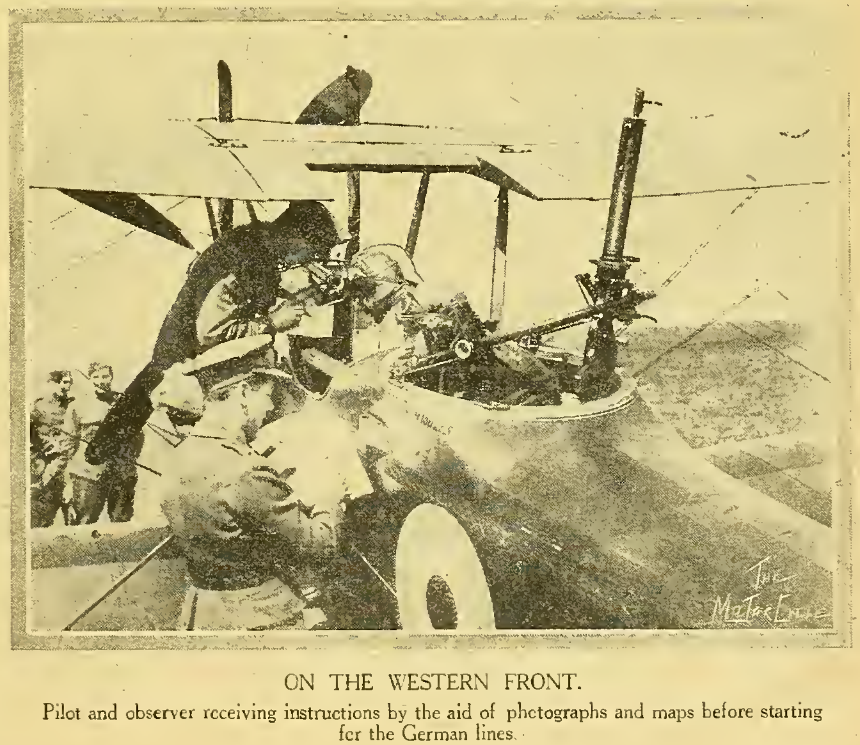
Questions We Dare Not Answer.

How do anti-aircraft gunners distinguish between British and German planes at night?

How does a defending British pilot ascertain whether the planes he views are Gothas or not?

When shall we bomb Essen?

When shall we bomb Berlin?



ON THE WESTERN FRONT.

Pilot and observer receiving instructions by the aid of photographs and maps before starting for the German lines.

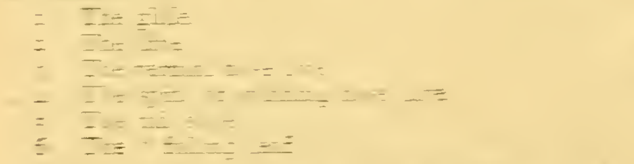
STUNT FLYING

PART V. By "Torque."

In this instalment our contributor describes several methods of descending.

The [illegible] stunts described in the last instalment may be used as a means of dropping a [illegible] feet or so. As most of our [illegible] [illegible] "stunt" descents are seldom desired or safe; they would bring [illegible] within reach of [illegible] guns. A short drop [illegible] is a very different matter, and [illegible] to get a machine out of a tangle, and [illegible]. [illegible], on the other hand, when fighting over his own soil, frequently indulges in quick descents, sometimes to get away as fast as possible, sometimes to tempt our men to follow him over a nest of concealed guns. There is great variety in the methods of descending, though these may be tabulated:—

Fig. 2.



Normal gliding angle. Nose dive. Vertical nose dive.

1. The glide.
2. The dive.
3. The vertical nose dive.
4. The spin or spinning nose dive.
5. The tail slide.
6. The "falling leaf."

The "glide" is the normal method of descent, and [illegible]. In a glide a pilot merely [illegible] down his engine [illegible] and the [illegible] with the nose falling, along a path slanting downwards at an angle of about 1 in 8. During a descent gravity soon takes up the work performed by the engine in flat or climbing flight, and provokes a reaction from the planes. This reaction is not powerful enough to render flat flight or climbing possible, but it cushions the descent. The machine glides safely and comfortably earthwards at its "natural gliding angle," which may be somewhere about 1 in 8. The pilot can increase this gliding angle by any amount up to the vertical at his pleasure; he has merely to lift the tail up by using his elevators, and at one time the term "dive" was reserved in flying parlance for descents at a steep angle. Similarly the speed of a glide or dive can be affected by keeping the engine fully on. Finally, the path of the dive can be modified by the use of the rudder. In all stunt descents the limit is fixed by two factors. The first is the altitude from which the descent is made; the second is the amount of stress which the structure of the machine can stand. To name examples, all the steep descents have to be converted into glides before safe landing or a resumption of horizontal flight is possible; and the conversion of a steep angle into the natural angle occupies some distance. Secondly, when a machine is flattened out of a vertical nose dive into a glide, a colossal strain is thrown on the controls, the planes, and the bracing wires. A machine which is damaged by gunfire, or is aged and somewhat feeble in its parts, cannot be subjected to such stresses.

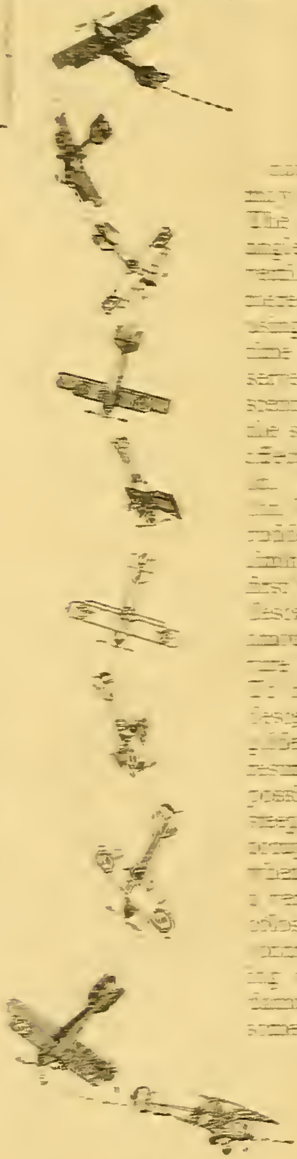


Fig. 1.

The spinning nose dive.

The Spinning Nose Dive

The spinning nose dive is a continuous spiral descent, and has already been described in *The Motor Cycle* under "Flying Feats and Tactics." It is obtained by throttling down the engine and stalling the machine with the rudder hard over. [illegible] it was thought

Stunt Flying.—

impossible to extricate a machine from a spin. To-day it is a deliberate manœuvre. The early machines often met their doom in spins, for two reasons. The first was that, when a machine spins, the rudder and elevator "change places," as the cant term is. More accurately, when a machine is tilted over on to its side, the elevators begin to control its side-to-side motion instead of the fore-and-aft inclination, which is their normal business; and simultaneously the rudder surrenders control of the side-to-side motion to the elevators, and steals from them control of the fore-and-aft motion. This was very disconcerting to pioneers experimenting in a new science. If they had thought the matter out previously to ascending and could have kept their heads when the dizzy spin suddenly developed, they were still up against a purely practical difficulty. The machine had not spun far before it developed a special spinning momentum, which made it extremely loth to resume the straight path; and the leverage of the control surfaces was insufficient to overcome this spinning momentum. With modern controls a pilot can wrench a machine out of a spin; or if he centralises his controls, the 'bus will do it on its own.

The tail-slide is less mysterious than other stunts. The elevator is used to force up the nose of the machine till it is trying to climb at an impossibly steep angle. It will eventually stall, with its longitudinal axis nearly or quite vertical. Gravity will then get to work, as the planes are in no position to furnish lift, and it falls like a plummet, tail first. The natural nose heaviness gradually pulls its nose down, and if it had sufficient altitude at the commencement of the slide it merges harmlessly into a normal glide.

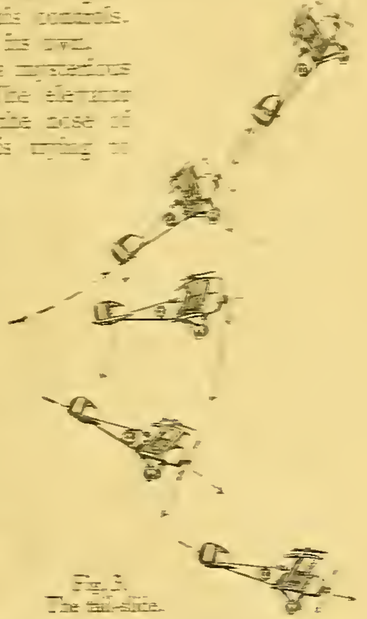

Fig. 3.
The tail-slide.

The Falling Leaf

The "falling leaf," like the "roll," belongs rather to the catalogue of exhibition tricks than to the list of fighting stunts, and is perhaps the prettiest in the trick-flier's bag. The nose of the machine is tilted up just enough to prevent a normal glide developing at once, and the engine is throttled down. The machine will then drop more or less vertically until it gets its nose down and develops a glide. As it drops the pilot works the wingtips to rock it gently from side to side, first over towards the right wing tip, then towards the left, and so on. The distance during which this tumble can be maintained is limited, of course. As forward way is lost, the elevators can no longer be used to keep the nose up, and the "falling leaf" ends in a glide, as the powerful weight in front pulls the nose down.

The fighting value of these stunts varies. In manœuvre it is the unexpected that tells. The pilot who stalls his machine when an enemy is diving at him is merely reading a leaf from the book of the footballer who stops dead to evade a rush tackle. It is even conceivable that to glide a few hundred feet at the slow natural angle and in a straight line might disconcert an attacking foe, who might be expecting some very complex manœuvre. As I said before, to keep the enemy guessing is the golden rule, and it is probable that every conceivable stunt is occasionally employed in warfare, though the favourites are those which facilitate lightning changes of altitude or direction, so that the rapid forms of descent are used at least a thousand times for every once that slower loops are resorted to. The steeper descents are very apt to over-oil the front cylinders. This point is a help when one is trying to escape with a Hun back; the smoking exhaust may delude your assailant into fancying you are on fire. But it is a grave danger when you are over the Hun lines, and a frightful nuisance if you intend to attack again in a moment or two, as one or more plugs may oil up when you recommence to climb. Consequently, really steep dives are usually broken off after a short drop unless the pilot is trying to escape.

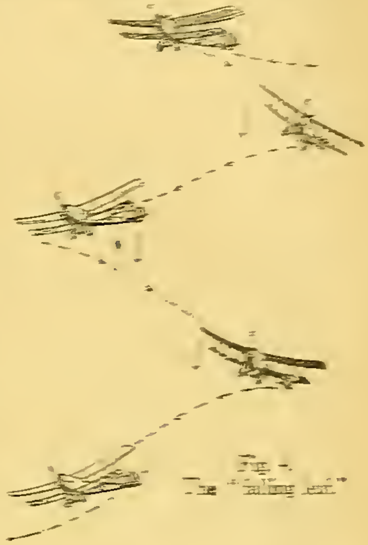

Fig. 4.
The "falling leaf."

It is, of course, possible to achieve fiendish speeds by diving steeply with the engine fully on, and all pilots are nervous of what can be done in this line. There are three dangers in such an act. The first is that the plane itself will collapse when it is pulled out of a dive at speeds approaching 200 m.p.h. The second is that the engine will be revved up to speeds for which it was not designed, and something may "give." A third is that it is not good for even the finest physique to undergo marked changes of atmospheric pressure in a very brief period.

CHEAPER THAN A CAR?

According to Mr. G. Holt Thomas, a small aeroplane is considerably cheaper to run than any car. A machine capable of 100 m.p.h. and of carrying a load of 250 lb. (including the pilot and fuel) can be maintained (including repairs, housing, etc.) for an average sum of 1½d. per mile, and therefore represents the cheapest form of long distance locomotion, with the two exceptions of the motor cycle and third-class travel. The housing of an aeroplane, however, would be the most difficult question to some

RICHTHOFEN'S DIARY.

(REVIEWED BY "TORQUE.")

AN APPRECIATION OF A GERMAN AIRMAN.

MR. C. G. GREY has done us all a service in translating and publishing the diary of Baron von Richthofen, the crack German scout, who was recently shot down by a British airman after downing eighty Allied machines. The general impression in the R.A.F. is that the dead baron was a gentleman, and, as far as German military orders permitted him to be, a sportsman. Accepting this impression as just to his memory, the slimy trail of a propagandist Hun editor is smeared over what remains of the simple, boyish pages of this dead hero's diary. Here and there a page still stands as originally written, and rings true, as, for example, the record of his hero worships when he was an obscure subaltern, his sorrow at leaving his pals when he was transferred, his experiences in his first solo flight, and his first fight. For the rest, by suppression and insertion and ingeniously faked implications and innuendoes, his ingenuous record has been marred by the hand of some psychological underling. With this reservation the book is splendid reading: and any reader sufficiently sophisticated to trace the hand of the official German editor will take a real liking to the lovable boy whose brief career as a soldier is *camouflaged* in this book.

To quote instances of suppression, superficial reading of the book creates the impression that Richthofen was in the daily habit of shooting down one or more English pilots before breakfast. The Baron made his first flight over the lines in June, 1915, and was killed in April, 1918. By implication he shot down over 1,000 Allied machines: in sober fact his bag averaged rather under four per month. He is further made to write as if he wandered about alone, or with perhaps one companion scout, searching the vacant air for enemy planes. On occasions the German pilots unquestionably fight like tigers, taking all risks: when a push is afoot the Hun Higher Command does not spare pilots or machines. But neither Richthofen nor any other German pilot normally pursues the offensive regardless of danger. Fritz is, above all things, logical. He has fewer machines than we have, and his machines are not so good. His correct policy is to conserve his flights, whilst missing no chance of weakening ours by a prudent war of attrition. So in normal times and on quiet sectors the official Hun tactics are somewhat as follows:

(1.) To fight, as much as may be, behind his own lines.

(2.) To confine attacks to surprise dives, and to go down if the surprise swoop fails.

(3.) To patrol in large formations and restrict solitary fights to special emergencies.

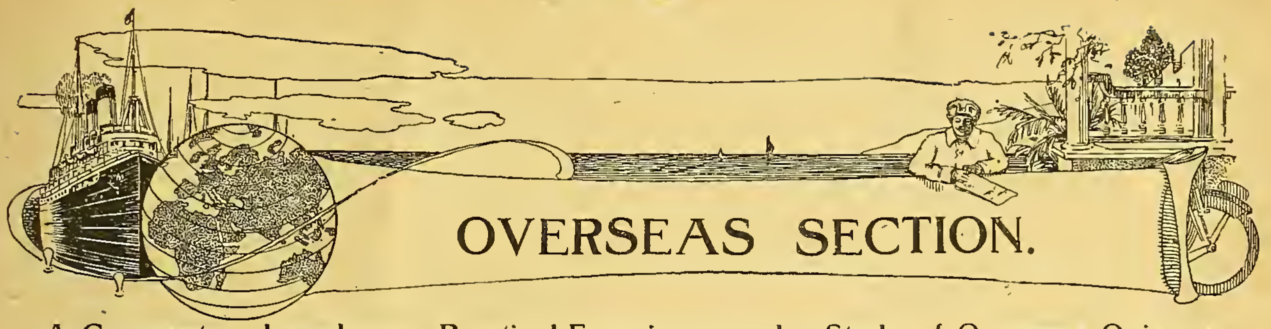
(4.) To keep a sharp look-out for damaged Allied planes.

Whether the baron liked these tactics is another matter: his General would see that he adopted them, except when an aerial push heralded an infantry push, and bolder deeds were essential. But for these tactics the baron would never have survived for $2\frac{3}{4}$ years. Moreover, being logical enough to adopt such tactics, the Hun is logical enough to see that an honest admission on the point would make poor reading in Entente and neutral countries: so the exact reverse is suggested throughout most of the book.

It would be very interesting to know whether the Hun censor has excised the baron's more recent references to Allied men, machines, and methods. What is said is extremely contemptuous. The British pilots appear as foolhardy and inexpert: the French as cowards and given to shady tricks. These references are possibly authentic. In his earlier days the baron undoubtedly met a number of British pilots whose training had been grossly inadequate, especially in gunnery: and we can guess how bravely these half-trained boys went to meet death at the hands of a man who had training and experience behind him.

The diary cunningly implies that casualties in the German air service are practically unheard of, and that when they occur they are due to sheer bad luck. As edited by the German Censor, the book is a magnificent example of wily Hun propaganda, and it is rather a pity that it has been allowed to appear in English without a covering preface pointing out in downright fashion that the work is, on the whole, a cunning fake.

R.A.F. men salving bombs from a wrecked German aeroplane brought down on the Western Front.



OVERSEAS SECTION.

A Commentary based upon Practical Experience and a Study of Overseas Opinons.

Clutches for Overseas Mounts. It is difficult to arrive at a decision as to which is the best type of clutch to withstand the continuous stopping and general hard usage to which this component is often subjected Overseas. Naturally, the best design of clutch is one having a very ample friction surface, so that it operates under light pressure, thus reducing the grinding process to which the surfaces are subjected, but the question as to the best material remains.

In the early days of improved transmission small clutches were the common order; one can recall heavy tricar outfits having cone clutches no larger than saucers, and motor cycles with the same fitment, but of even less diameter, with the result that even with the enormously powerful springs employed slip was inevitable and the friction faces literally peeled away. The multiple-disc hub clutch was the next step, and though this afforded a much greater friction surface it ran at such low speed and was subjected to such heavy torque that its gripping powers generally proved inadequate. To-day we have the countershaft high speed clutch of large diameter, operating under moderately light pressure, and giving entirely satisfactory results under the normal conditions of riding.

But the conditions Overseas are not always normal, and often the clutch comes in for more than its share of abuse. Should it be unreliable in operation the gear box suffers, and on its wearing properties largely depends the general reliability of the machine. Even though the clutch be sufficiently large, it must be made of the proper material to withstand the hard wear it is likely to receive, and it might be worth while briefly to review the various types of clutch employed in present-pay practice.

* * *

Present-day Designs. The dry plate cork insert clutch is one of the most popular types, and for the highways and byways of Great Britain it is excellent. This type has won its popularity chiefly on account of its sweetness of engagement, though its simplicity and cheapness of production have perhaps had no little to do with it. In the universal model, however, the cork insert clutch falls short of the mark in that it is not indestructible. The corks can be reduced to the smouldering point with comparatively little effort when a heavy load is carried over extremely difficult going, and though in England this point may never be reached during the ordinary course of touring, we ourselves have known it to occur—not merely once, but often—under extreme conditions. The cork inserts wear well and are comparatively easy to renew, no fresh part being required from the makers, and while this is a great point in their favour, the heat question is a serious drawback.

Next we have the dry plate clutch furnished with a fireproof and renewable lining in conjunction with metal—American pattern. This type of clutch is, if anything, better than the cork insert variety, in that it cannot be burnt out, but its wearing properties are not equal to those of the metal-to-metal wet plate clutch. Also, in common with other types of clutch, the surfaces of which permit a certain amount of yield, the point of "take off" is somewhat indefinite, and the delicacy of control rather a matter of speculation. It is, however, an excellent type of clutch, perhaps better adapted to the heavy and powerful type of mount than to the light solo machine.

* * *

The Metal-to-metal Clutch. Lastly, we have the metal-to-metal, probably phosphor bronze to steel, wet plate clutch. This is a type we have always favoured on account of its wearing properties, its indestructibility, and its smooth action.

One great point in favour of the metal-to-metal wet plate clutch is that the plates being thin, a great number can be packed into a very limited space, with the result that a very large friction surface can be obtained, and consequently a light spring used, hence its adaptability to hand control. The objection to the type is that, unless the adjustment be perfect, the clutch is never quite free, which is extremely bad for the gear box and not very convenient for the rider.

Though it is practically impossible for this type of clutch actually to cause failure, it is not without its drawbacks. The oil film between each plate is a matter of theory only after an hour's stopping, and thereafter the plates are run dry. To obtain good results from a metal plate clutch it should be propped open when the machine is left standing after hard use, as this permits the little lubricant that may be about to regain the friction surfaces, but the fact remains that for 70% of its time the metal plate clutch is running dry, so the question arises as to whether it is worth while to make any provision whatever for oiling it. Would it not be better to design and construct the clutch to run without lubricant?

From the Overseas riders' point of view, the objection to the metal-to-metal type is that it is necessary to keep a few spare plates in hand. Though a hardy clutch, in one way it is a more delicate one than the composition lined, because, after a certain point, there is nothing for it but renewals if perfect operation is to be resumed.

Overseas Section.—

A Desirable Design.

SUMMING up, then, the choice lies between the dry plate composition-lined and the wet plate metal-to-metal. The former demands no special provision in the way of an oil-proof front chain case, while the latter does. The latter, however, is infinitely more applicable to handle-bar control—not only on account of the lightness of the spring that can be employed, but because there is no yield on the friction faces, and therefore a very small range of movement is necessary. In the Overseas model, however, the necessity for spares should be cut down to an absolute minimum, and it is easier to purchase a square yard of composition lining than it is to obtain specially cut plates.

We have arrived, then, at the fact that every type of clutch wears out and requires renewals. What should be aimed at in the Overseas model is to provide a clutch, whether wet plate or dry plate, which will *not* wear quickly. If six plates are considered necessary for British use, then at least nine plates will be necessary for use in pioneer lands. Because a machine has stood the most scorching six days' test in England it is by no means certain that it will stand up to Overseas use.

IN THE LAND OF THE VINES.

A convoy of motor cycle machine guns in Italy led by an officer on a W.D. Triumph. Little has been heard of late of this particular arm, but it is doing good work on many fronts.

A Selection of Letters from Readers scattered all over the World.

A Two-stroke in N.S.W.

MR. G. W. ANDERSON, of Gilgandra, New South Wales, writes the following appreciative letter of his experiences with a Connaught two-stroke:

"I take great interest in your paper, *The Motor Cycle*. The only trouble is that it does not come regularly enough, as sometimes I do not get it for months, and then four or five at once. Many do not turn up at all.

"I thought I would let you know of my experience of my Connaught motor cycle. I have had it nearly two and a half years, and have done 7,000 odd miles, and the engine has cost me only 7s. 6d. for new small end bush and 2s. 6d. for new piston ring, which speaks well for the simplicity and few working parts of a two-stroke. I have an Albion two-speed gear, but very, very seldom use second gear, as there is plenty of power in the engine to go anywhere on top. I always average 125 miles to the gallon, and this is not done by any faking, as the carburetter is set exactly the same as when delivered to me. This mileage is registered by a Corbin-Brown speedometer.

"*Re* two-stroke rattle, I always find that the Connaught starts to rattle as soon as the top ring starts sticking in the piston ring groove, and the rattle always disappears as soon as it is cleaned. I have found this always without fail. The only objection I have is that the lubrication is messy, but there is no doubt that it works well. As for four-stroking, I never get a sign of it. The carburetter is an Amac with 24 jet.

"I can average 20 to 30 m.p.h. without any sign of overheating or petering out. The flexibility of the engine is simply marvellous, as the roads are bush tracks and very sandy in places, and the sandy patches are where one appreciates flexibility. The original belt is still in use and looks practically new. I have fitted two new tyres."

War Lessons and the Machine of the Future.

Although not an "Overseas" letter in our usual interpretation of the term, the following communication from "ELDON," B.E.F., France, is given here, as it deals primarily with Overseas matters:

"May I be allowed to air my views on your article dealing with the subject of 'Overseas Trade after the War' in your issue of May 30th?

"It is all very well to say that British manufacturers may have been brought, through war requirements, to see the possibilities of 'quantity' production, but what about the radical changes in design which have been proved necessary by the tests of war work with the various Expeditionary Forces? The requirements of the Overseas market have for years been drummed into us by our Colonial brothers, and the war has completely demonstrated the truth of their complaints.

"The Army authorities no doubt have excellent arguments in defence of their refusal to allow any alteration in the design of motor cycles supplied to them, but the fact remains that, owing to this refusal, the many improvements which could, and no doubt would, have been made have been denied the splendid trying-out they would have received on Active Service. In the case of those manufacturers whose products were not made use of by the War Department, of what

Overseas Section.—

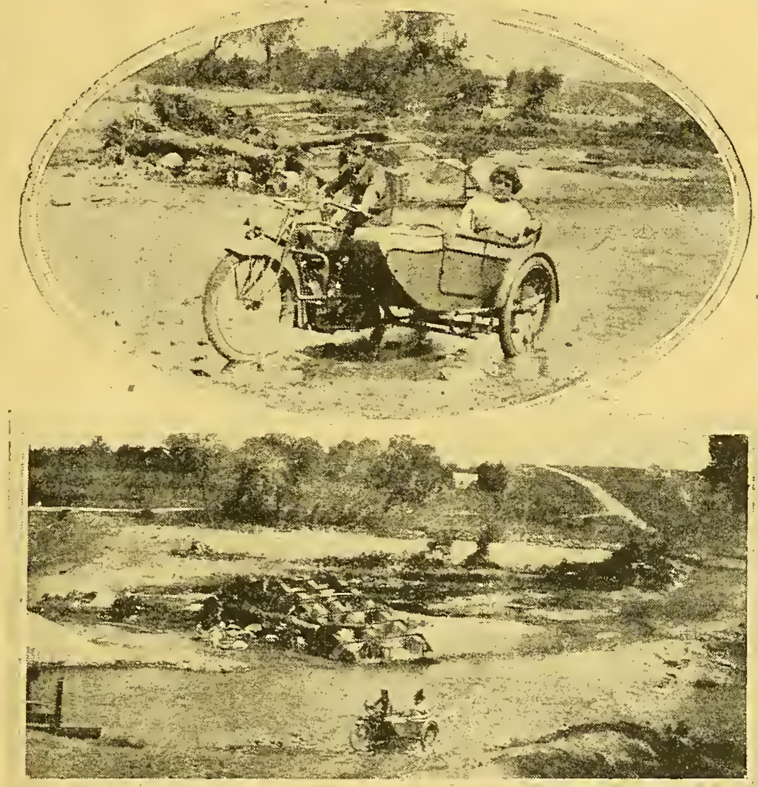
assistance can the war have been to them in finding out the weak spots in their designs?

"Then there must have been dozens of small concerns who had just entered, or were on the point of entering, the motor cycle market when war broke out. Some of these people must have had new and good designs, but, owing to the war, they were squashed, and may never rise again.

"'Quantity production' sounds all very fine and large, but in order to attain it, you must have your market: and in order to get your market, you must have the *right article.*

"So far, I fail to see that manufacturers have learned anything in the direction of radically improving the design of their machines during the war. The 'post-war' models I see so largely advertised look to me very little different from the 1914 models.

"May I conclude by saying that it tickles me immensely to read the gushing effusions in advertisements and elsewhere to the effect that Mr. So-and-so has ridden a — h.p. Triglas for 3,000 miles and had no trouble at all. Three thousand miles! Heavens, I should think not! If I had a modern machine that gave me any mechanical trouble inside four times that distance, I should sell to the first unsuspecting 'mug' that came along."



Showing the devastation wrought by the floods near Johannesburg recently. A heavy girder bridge spanning Crocodile River was completely swept away. The photograph shows Mr. L. Tregoning's Harley-Davidson crossing the drift.

Roads in the Johannesburg District.

MR. L. TREGONING, writing from Mayfair, Johannesburg, says: "I am sending some photographs which may perhaps interest you as showing the effects of the recent heavy rains. Most of the roads outside the town are in a pretty bad state. The photographs show the bridge at Mulder's Drift before and after the floods. It is situated about nineteen miles from Johannesburg, and spans the Crocodile or Limpopo River about six miles from its source. The flood at its highest was well over the hand rails. All traffic has now to use the old drift, where the motor cycle is seen. It is a fair specimen of a South African river crossing.

"Some correspondents who write regarding Colonial models seem to want a Rolls-Royce ambulance, or, better still, an ox waggon. I see one wants not less than 8in. ground clearance. Perhaps he would like the engine on top of the tank.

"I wish your valuable paper every success."

English and American Machines in Canada.

The following is a further contribution to the subject raised by Mr. Warne, of Toronto, in two previous letters:

"I notice in *The Motor Cycle*, Overseas Section (April 25th), Mr. W. R. Warne, of Toronto, Canada, is answering the criticism of his letter written October 25th, 1917. I may state that I also hail from Canada, and Toronto happens to be my home town. I wonder if the Editor, or some reader, would be interested enough to drop a line to the T.M.C., Toronto, enquiring just what make of machine Mr. W. R. Warne did ride. I have had the pleasure of riding Triumph machines from the fixed engine 1911 plugger stage to the 1915 three-speed model, with and without a sidecar, over all kinds of roads, and not once in those five years of 'experimental' riding on five different models did I have a single breakdown or a moment's delay. Since then, and between those dates, I have ridden nearly all of the American makes —if not all—and I am sorry to say the same 'record of service' cannot be given to them.

"I was the owner of a 1914 American 7-9 h.p. twin, single gear of 4½ to 1. This machine was used entirely as a solo machine for over a year. During that time it was driven at very high speeds over the worst roads in the country—sand, rock, and mud. When this machine was sold it was ready for the scrap-heap, being beyond repair.

"Now the Triumphs were given practically the same abuse and not one failed. When they were finally sold they were equal in reliability to new machines, if not in looks, and now I want it understood that I am not limiting myself to one machine as a 'test example.' Far from it. I claim any American machine will wear out under the same strain long before a good English-made ''bus' will, and people who have ridden both types *hard* will back me up in all I say.

"Except as a private rider, I have no other interest in Mr. Warne's letter.

"This much from

A ROUGH-RIDING
CANADIAN."

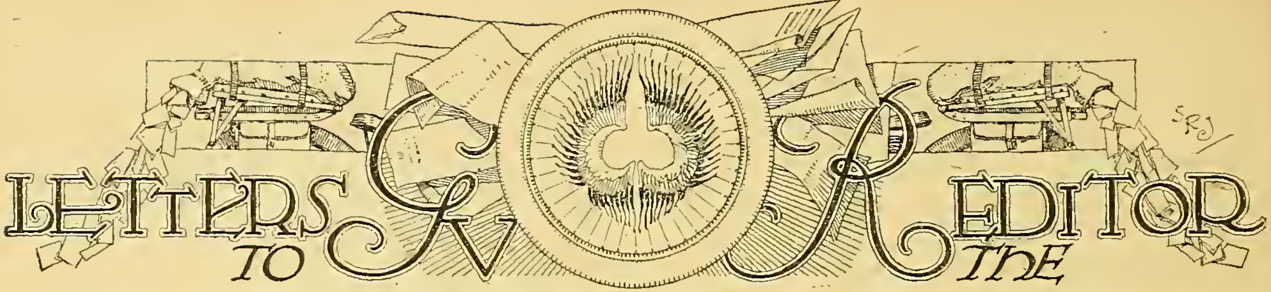
MR. W. GREENWOOD, of Toronto, sends us the following further contribution to the above discussion:

"In your issue of April 25th Mr. Warne seems surprised that all the British makers are not tumbling over one another to get his advice, as only one wrote him. I think the makers will hesitate before they establish showrooms, workshops, stores, and offices in Toronto, with branches in Montreal and the Western capitals, as he suggests. Why the principal headquarters in Toronto? Montreal is a larger city, and all goods are landed there. Why bring them to Toronto and then have to send them back to the Montreal depôt—330 miles? There is no doubt that the originator of this great scheme would be consulted in this matter. Mr. Warne quotes me as saying: 'In the pre-war competition only two British machines competed.' I said that *two Triumphs* started and finished first and second. What would Mr. Warne have said about the preponderance of the American machines had I quoted the following?

"'T.M.C. HILL-CLIMB.

"'From *Canadian Motorcycle*, January, 1913.

"'A significant feature of this event was the fact that all the contestants rode British mounts, the Triumph being almost universally used, with the exception of one rider who rode a Rudge. British machines with their small wheels are admirably adapted to work of this kind, and that they could take the steepest hills without trouble was made evident by the manner in which they took the test hill which was as steep as the majority encountered in country riding. The speed at which the hill was climbed by the various contestants can be closely guessed at when it is known that to do the distance in 25s. a speed of 26 m.p.h. was necessary. After the trial one competitor rode up the hill in 22s. dead, or over 30 m.p.h. The hill is 960ft. long, and has a grade of 1 in 6.'"



LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address

HYDROGEN FROM WATER.

Sir,—I have followed the discussion *re* hydrogen as a fuel, and have come to the conclusion that the following might be of some use. Why should not an accumulator be used, as I have electrolised water in a U tube by means of one with good results? The tank could be lined with porcelain or glass, and a pipe let in at the top to convey the gas to the induction pipe. I fail to see why this could not be used with, at any rate, partial success. Both oxygen and hydrogen would be used, both going through the same pipe. I may add that I have *not* fitted it to my machine, and it is purely theoretical. HENRY CLAY.

Sir,—I was much interested in "Pilot's" letter. Like everyone else, we suffer from the petrol restrictions, but for some time past we have been experimenting with water as a fuel. The alterations have been made on a 7-9 h.p. twin.

At first we had no voltmeter to test the magneto with, but one bright youth volunteered to try with his tongue; we now work unmolested. By pulling a string an ingenious arrangement of rollers, emery paper, and friction discs is set in motion, and after about ten minutes' work the cylinder heads become red hot. These boil the water situated in little tanks above them, and the steam passes through a network of tubes into the frame. In the frame we have seccotined an immense quantity of iron filings, and as the steam passes over these the oxygen combines and the hydrogen goes on its weary way. By means of scoops and blowers the hydrogen is brought into the cylinders and fired by the red hot heads. On this machine we can reverse; it all depends on the compression. If we tighten up the cylinder holding-down nuts we get normal compression and pre-ignition, and back we go. If we slack off the nuts we get low compression, and it works splendidly. We cannot understand why "Pilot" gets his misfiring, as we indulge in speeds approaching 90 m.p.h., and we think he must have a worm on the needle valve of his top feed carburetter. CADET.

Dartmouth.

THE SINGLE-CYLINDER IN COMPETITIONS.

Sir,—Anyone who is guided by facts, and not by fads or fancies, must find it impossible to answer the able article by Dean Barry in favour of the single. Unfortunately, there are a great number of people who *will* vote for anything new, no matter whether it is an improvement or not. To-day, the single still stands unrivalled as the most efficient and practical machine on the market. There is one point, however, which I think your correspondent has overlooked. He seems to infer that for sidecar work the choice lies between the over-powered big twin and the under-powered 3½ h.p. single. Admitting that a lot of pleasure can be got from the latter, it is still a fact that there are many occasions when the rider will want more power. Here, what is, I think, the most practical sidecar mount comes in—the "big single." I can only speak from experience of the Norton, but this machine certainly "fills the bill," and I have yet to find a better. The engine gives 7 h.p. on the back wheel at 1,100 r.p.m., and without racing 10-12 h.p. can be got. This is all that can be got out of the best 5-6 h.p. twin on the market, and the engine is vastly easier to keep in tune, and far less trouble on the road owing to its simple construction and few working parts.

The only fault I have to find with it is its name, the "Big Four"—a remnant of old times when the motor cycle engine was not nearly so efficient as it is to-day.

If an engine of 560 c.c. is called by other makers a "four," it is obvious that one of the 633 c.c. should be called by another name. I have no interest in any motor cycle company, but I think that the big single should certainly be better known and tested. If this were done, I think there would be few twins to be seen on the road.

Beech, Alton. M. HITCHCOCK.

STUNT FLYING.

Sir,—I cannot profess to compete with W. G. Aston either in draughtsmanship or technical calibre; but I rather fancy the point he has raised is mainly one of terminology. I have read his analysis of the "roll," and feel that I have rather rushed in where angels fear to tread, as his inimitable pencil shunned the task of depicting an aeroplane following the path of a "pulled out corkscrew." But I notice that he limits the "roll" to corkscrews commencing with a "zoom." Now, to take an extreme instance, a spinning nose dive might be described as a "roll," being a corkscrew with a vertical axis, whereas Mr. Aston's roll is a corkscrew with a horizontal axis. It is further possible to make a machine follow a corkscrew path with an inclined axis. Are all these manœuvres "rolls"? Mr. Aston would limit the term "roll" to corkscrews with an approximately horizontal axis, or, rather, to a horizontal corkscrew with a wilting tip. Some R.A.F. instructors definitely assert that a "roll" can be performed with the engine on or off. Mr. Aston says it is impossible to "roll" unless you commence with a "zoom." Many Service pilots are dropping the term "roll," apparently because of this ambiguity, and prefer the term "side loop."

I think we should all be interested if Mr. Aston would treat us to a technical analysis of corkscrews with axes of various inclinations. TORQUE.

A SATISFACTORY GEAR BOX.

Sir,—I have seen several appreciations of the A.B.C. engine in your columns from time to time, but I cannot remember any special reference to the A.B.C. gear box.

I have had occasion to dismantle mine recently, and thought perhaps some of your readers might be interested to know how it has worn.

During the last two years and a half I have ridden the machine daily, winter and summer, covering some 20,000 miles, mostly over very bad roads. During this time the clutch had to be adjusted once, and to do this a small nut had to be given three turns. This was the only attention, other than periodical oiling, that the gear box has had till about a month ago, when a slight grinding, which was felt rather than heard, began to develop. On examination, the four self-centring Skefko ball races on which the main and layshafts run, as well as all the spur wheels, shafts, etc., inside the box, were still in perfect condition. One brass bush had developed play to the extent of four-thousandths of an inch (measured by micrometer), and the roller bearing, on which the clutch spins, owing to oil channels getting clogged up and to the breaking of a roller, had developed one-thirty-second of an inch play. Considering the long, hard wear that the gear box has had, I think this is no mean record.

While the gear box was dismantled and on the bench, it happened that two standard English cars, 10 h.p. and 12 h.p. respectively, were in the shop for gear box repairs, and although the A.B.C. box was only half the size and less than half the weight, it was, in my opinion, both stronger and more efficient than either of the others. A.I.C.

DIFFICULT STARTING.

Sir,—Mr. Ellison's tip is capital. I have had four B.S.A.'s, and have nothing but praise for the sturdiness of the mount and its meek acceptance of mud and misuse.

My only grumble is on the score of vibration, and as I am subject to attacks of Anno Domini, I want to know how to save my feet doing a step-dance on the footboards. Terry links ward off neuritis from the arms all right, but anything over 20 m.p.h. castigates my ignorance.

(Rev.) W. M. W. PITCHFORD.

Sir,—I have read the letters in *The Motor Cycle* regarding the B.S.A. 4¼ h.p. machine.

I have owned four B.S.A.'s. The last one—a 1916 model—had 13,000 miles to its credit after seven months from leaving the works. Its repair bill came to a few coppers for a kick-starter crank spring. Tyres, of course, I have omitted, and I have done Manchester to Tynemouth (180$\frac{3}{10}$ miles by Cowey) in eight hours, during the winter months at that. I have nothing but praise for the machine.

To come now to the difficult starting which a lot of big single riders experience. I have generally found when I have been asked to inspect these machines that the trouble was due to the carburetter, the jet adjusting screw being opened too much.

I find the best setting of this for starting is to have it one-quarter open, air lever closed, and throttle a third open, magneto advance lever two-thirds advanced (depending on the slack in magneto driving chain, of course), a few drops of petrol through the compression tap, put engine into low gear, and kick start (a hefty kick), and if the machine is in anything like trim it will start up the first or second kick, and when once running the jet adjusting screw can be adjusted to the correct setting. The B.S.A. carburetter is the finest, in my opinion, fitted to any motor cycle, and the B.S.A. machine throughout is one of the most easily adjusted on the market. I only know of one nut that is at all difficult to get at on the machine. I ride all makes, but I always get on a B.S.A. with the knowledge I shall have a good run.

To those who do not mind using a little more oil, and have the time to do the extra decarbonising it entails, I should like to say that the B.S.A. engine can be flooded with oil, and seems to revel in it.

The B.S.A. front belt rim brake if lubricated and adjusted properly is a most efficient one. E. FOSTER.

THE FOUR-CYLINDER F.N.

Sir,—The gears mentioned are standard. "Canterbury" will find the 6 to 1 gear not too low, unless he keeps the engine in top hole form. I presume his is an a.o.i.v. When building the engine up again I should advise fitting in a piece of fine gauze under the extra air inlet, and also a piece where the carburetter is joined to the induction pipe; they will assist vaporisation.

Personally, I prefer a four-cylinder machine, and must say the 1913 F.N. I recently sold gave me good service. I could do 75 to 80 m.p.g. As for speed, he will find his engine doing "some" revs. if he gets up to 35 m.p.h. The F.N., in my opinion, is not one on which record speeds can be made. I always found this class of machine very economical and as comfortable as a car.

The weakest part of the machine is the frame. I could never understand why a stronger tube was not used, and "Canterbury" will find a sidecar a severe strain on the steering head. LK 1831.

Stroud Green.

FLAT TWIN INDUCTION SYSTEMS.

Sir,—We notice in publishing the description of the new Raleigh twin opposed particular attention was drawn to the induction system.

It will no doubt interest you to learn that in 1910 we produced a 5 h.p. opposed twin engine, embodying an almost identical feature, with the exception that, in addition to part of the induction pipe cast integral with the crank case, the remainder of the pipe formed a part of the cylinder casting, there being no union nuts or flanges of any description, the ports in the cylinders registering with the pipe in the crank case when the cylinders were bolted in position.

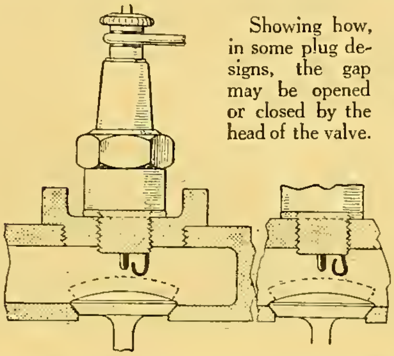
We have also at present an engine embodying this system in a modified form, and in the 1914 T.T. race we used an induction in which the carburetter lead was part and parcel of the timing case, two short pipes connecting these to the cylinders.

Another similarity between the early 5 h.p. Douglas and the Raleigh is to be found in the frame construction, both using straight duplex down tubes and other frame members.

DOUGLAS MOTORS, LTD.

FAULTY SPARKING PLUGS.

Sir,—From an article by "Road Rider," written some time ago, I see that a correspondent suffers from sparking plugs "which automatically widen their sparking gap in use." He suggests faulty plugs, but may I suggest the following as the cause? The plug projects too far into the cylinder, so that the valve immediately beneath it hits the lower electrodes and knocks them further from the central electrode, as shown in the sketch. I once had a similar trouble on an old Minerva, but with a different type of plug, so that the points automatically closed up.



Showing how, in some plug designs, the gap may be opened or closed by the head of the valve.

G. BAGSHAWE (Lt., 9th/13th Tank Corps).

R.G.A. DESPATCH RIDERS.

Sir,—There seems to be a great deal of controversy in your columns regarding D.R.'s belonging to R.E. and R.A.F., but one seldom reads anything concerning the D.R.'s of the R.G.A. In my opinion, these D.R.'s do more hard work and under far worse conditions than any other D.R.'s. The R.G.A. rider starts where the R.E. rider leaves off, and continues his work up to the firing line, and as for the R.A.F. riders they seldom come within four or five miles of the batteries. I do not wish to belittle the work of the R.E. and R.A.F. riders, but in the majority of cases they have a "cushy" job compared with the battery riders. These men have to do their own repairs and adjustments, often under very bad conditions and with poor tools. The battery rider gets a variety of jobs, driving officers to O.P.'s or as near as possible, taking despatches to Brigade H.Q.'s, collecting small gun parts from ordnance workshops, etc. He has to be ready to go anywhere at a minute's notice, day or night, wet or fine, over the worst roads, solo or sidecar.

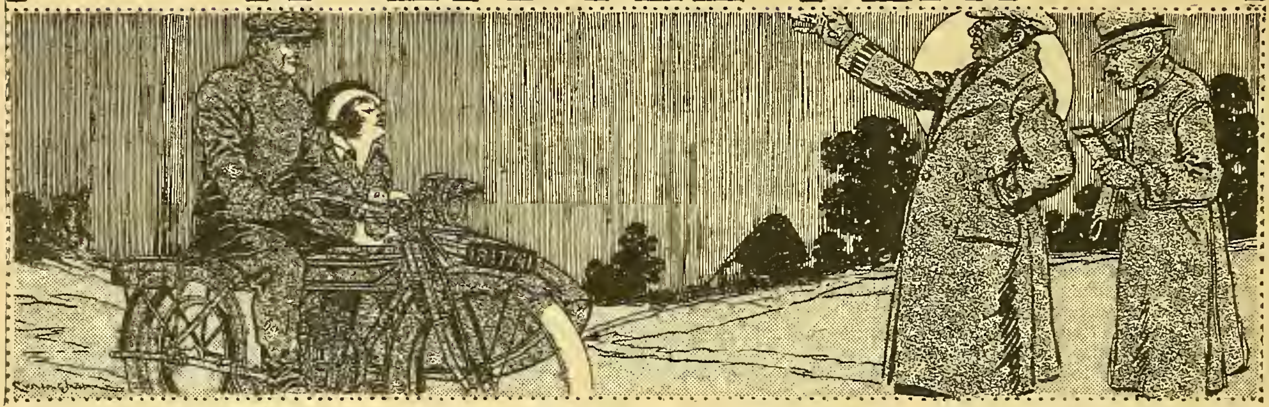
With regard to military utility of machines out here. We have three flat twin solos and one sidecar combination in our battery, and are constantly having trouble with front fork springs and spindles breaking, gear boxes working loose and causing chains to fly off, front down tubes of frame fracturing, etc. The sidecar chassis also give a lot of trouble, especially the springs and transverse rear tube, due mostly to being built too low and fouling edges of shell holes, large stones, ruts, etc. The power units on the whole are fairly good, but the kick-starter very often shirks its duties. These machines are not nearly so comfortable to ride as the single, the heavier weight and better riding position of the latter making it far easier to sit over bumpy roads. Engine vibration does not count on this work.

I may say I hold the rank of Staff-Sergeant Artificer, and in that capacity I do a good deal of riding to ordnance workshops, etc., and also do repairs to the machines if possible. My experience of motor cycles dates as far back as the days of surface carburetters and accumulator ignition, and I also have been out here in the R.G.A. since April, 1915, so I think I may claim to know what I am writing about.

I have been a regular reader of *The Motor Cycle* since its early days, and look forward eagerly to its arrival here every week. The articles it contains are just now very interesting, especially the descriptions of new ideas in engine design, transmissions, etc. At present I am busy with elimination of misfires, leaky pistons, and other mechanical misbehaviour of six females of the howitzer kind; but am looking forward to the time to come. TIFFY.

B.E.F.

A LITTLE PLAY



In one Defence-of-the-realm Act. By Bilbo.

DRAMATIS PERSONÆ:

1st Special Constable	A Knowing Bird.
2nd Special Constable	A Cure.
Motorist	A Caution.
Lady Passenger	A Oner.

SCENE: Any suburban road in any town.

TIME: 12.30 a.m. on any wet night in November, 1917.

N.B.—Although written in blank verse, nothing is to be inferred from this.

Ist and 2nd Specials discovered slowly patrolling the road with their collars turned up, trying to look useful.

1st Special (dejectedly): 'Tis weary work, this dull monotony,
From ten to two on chilly autumn nights
With nothing ever doing.

2nd Special (more dejectedly): Aye, it is,
And long before the hour of twelve has struck
You've torn the war to tatters and discussed
The many possibilities ahead
Were you but in command of our brave lads
On sea or land. That wearies me still more.

1st Special: At all events you cannot doubt my aunt
In Lancashire who knows that man—

2nd Special: I am
Fed up with all your aunts. You talk too much.

1st Special: There is naught else to do. In these hard times
It is not worth the burglar's while to steal,
And drunkards find their liquor hard to get,
Thus we have leisure.

2nd Special: True, and only those
Who talk remain at home, and we are all
Half suffocated in a flood of words
Poured out by such as you.

1st Special: Oh, very well,
If you don't like it—Ha! methinks I hear
A distant rhythmic beat betokening
The swift approach of some bold motorist
Who braves alike the weather and the Act.

2nd Special (brightening): Now may the gods reward the man who first
Remembered our lack-lustre hours of ease
And passed these regulations.

1st Special: Here he comes;
So do you flash your lamp and I will blow
A blast upon my whistle that would stop
Sir Douglas Haig himself. Then you shall see
Some sport, I warrant you. Now, watch me close,
Mark how I play him like a spinning trout,
Or even as a cat will tease a mouse.

[*Enter Motorist and Lady Passenger.*]

Halt! Halt! I say, and tell us by what right
You squander precious juice upon the road.

Motorist: Don't be alarmed, my dear; that awful sight
Which rises up before us in the murk
Is but a face—at least, I think it is.

1st Special: Now then, come off it.

Motorist: Yes! it moves; it speaks;
It is a face. I thought it was. But still
That's not his fault, poor chap.

Lady Pass.: How sad to think
Of any fellow-creature bearing such
Affliction through his life.

Motorist: Yes, yes, indeed,
Poor chap; it must be hard.

Lady Pass.: But we were taught
As children that we ought to pity those
In such a sorry state.

Motorist: I must admit
I've never met a greater tragedy,
And I have seen some sights.

1st Special: Come, none o' that,
Or you will make it harder for yourself.

Motorist: I think the voice is even worse, don't you?

Lady Pass.: It takes me back again to my old home,
Where corn-crakes got their feet wet in the dew,
And, having caught their death of cold, would come
Beneath my window half the night, and croak
With husky raucous voices.

1st Special: Look 'ee here,
Possess us of the facts that we demand,
And let me warn you that each word you speak
May be brought up as evidence in Court,
So drop this rot.

Lady Pass.: I wonder if it bites!

2nd Special: That goes down for a start to Number Two.

1st Special: The facts, I say, and failing an excuse
For this unpatriotic pleasure trip—

Motorist: Who talks of "pleasure" on a night like this?

1st Special: We'll hale you and your passenger forthwith
Before the strictest magistrate in town
To answer for your fault.

Motorist: I do believe
It is addressing us.

1st Special: Put that down sharp.

2nd Special: I've got it, man.

Motorist: Am I to understand
That all I say is being taken down
By Bolo Bert who stands with solemn frown
And licks his pencil at your side?

1st Special (grinning): You are.

Motorist: And will be read verbatim to the beak?

1st Special: You bet your life.

2nd Special: I'll read it word for word.

A Little Play.—

Motorist: Then let me tell you that your ruby nose,
Which glows like any rear light through the gloom—
Your hat, your hands, your uniform and boots,
And those anthropoid ears which catch the breeze:
That face—that lamentable face—in short,
Your whole get-up, doth like me not; so if
Your pretty little friend has got that down,
And promises to speak the speech before
The public court as I have tutored him,
That's all I ask. Life has no more to give.
And now, hence, fellow, let us on.

2nd Special (smiling largely): That's all
Down right enough.

1st Special: Then you can cut it out;
And do try not to be an owl, you owl.

2nd Special: An owl I may be, my nose is not
A tail lamp, nor my ears—

1st Special: Oh, do shut up.
Now then, me lad, this sort of thing won't do.
You't better drop it quick and let me see
Your licence and your petrol card; come on—

Motorist: Come where?

1st Special (assuming official manner): Perdooce yer licence
and—

Motorist: Say "Please."

1st Special: I want none o' your lip.

Motorist: You're not at home
In Germany, you know, just now.

2nd Special: Ho! Ho!

Lady Pass.: *I* thought it looked Teutonic, too.

2nd Special: Ha! Ha!

1st Special to 2nd do.: If you don't mind I'll break your
silly neck
In twenty diff'rent places.

2nd Special: Try it on
And see what happens.

Lady Pass.: Do!

1st Special: I will. But first
To settle your affair, my bonnie boy,
Just let me see your petrol card at once.

Motorist: I have no card.

1st Special: So much the worse for you,
For now you must explain yourself at length—
Where from? Where to? And what the business is
Which occupies you on a night like this.

Motorist: I don't see why I should. My starting point
Concerns you not. My goal is my affair.
My business is *my* business. And, what's more,
I hate all fools.

2nd Special: Ha! Ha! Mark how I play
Him like a spinning trout or as a cat
Will tease a mouse.

1st Special: That's done it. Now you come
Alonger me.

Motorist: What for?

1st Special: The law demands.

Motorist: I said I hated fools. Well, so I do,
And if you were not quite so plaguey smart
You'd see this cylinder of gas—

2nd Special: Ha! Ha!
I've got that down. It makes a decent line—
"When Gas meets Gas," or "Gas bags both." Ho! Ho!

1st Special: That puts the lid on.

2nd Special (reading his notes): "Anthropoid—"

1st Special: All right
My Bolo Bertie—

2nd Special: You say that again—

1st Special: Who licks his pencil, wasn't it?

2nd Special: Aye, aye,
And more he licks if need arise.

1st Special: Such as?

2nd Special: A nose which glows—a face—

1st Special: Now will I give
You something for yourself.

2nd Special: Again I say,
You try it on.

Lady Pass.: Yes, do!
(He does. In fact, they give one another a good deal. And under cover of this largesse the motorist drives on, calling out, "Chin-chin.")

1st Special: "Now will I give
You something for yourself."
2nd Special: "Again I say,
You try it on."
Lady Pass.: "Yes, do!"

* * *

THE ETERNAL QUESTION.

We have already referred to the rumour emanating from some unknown source, and once having quite a vogue, that petrol was to be released for unrestricted use during some period in July or August. The rumour is false.

Even if petrol were available, it is very improbable that its use would be legalised, for there are several indications that political questions have a certain bearing on the decision of the Petrol Control Department. The total abolition of private motoring was undoubtedly largely due to the Government's impression that the continued support of a section of the Labour Party was dependent upon the suppression of what is known as "joy-riding."

These sentiments, unreasonable and unpleasant as they may seem, have accounted for a considerable portion of our trouble. It is, perhaps, worth while to emphasise this aspect of the case to such bodies as those existing primarily for the securing of preferential treatment in petrol matters to certain sections of the community. Those people regarded, rightly or wrongly, by the Labour Party as their natural enemies were, in the obvious nature of things, able to use their motors after many motorists had given them up. Continued protests could only have one result, that under which we are now suffering—the total prohibition of motoring. And now those very agitators who caused the prohibition are loudest in their protests against it.

QUESTIONS & REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Carburetter Adjustment.

? I should be glad if you would enlighten me on the following subjects. I am the possessor of a 2½ h.p. New Imperial-Jap, fitted with a B. and B. single-jet carburetter: (1.) What is the bore, stroke, and c.c. of this engine? (2.) With the air lever fully open and throttle two-thirds open the best results are obtained. If the throttle is opened further it decreases the speed if anything. I considered fitting a larger choke tube, but the makers inform me that it is part and parcel of the carburetter and is not to be removed. (3.) I am using a 31 jet, which is rather large. Would a smaller jet improve things, and what size would you recommend?—J.B.S.

(1.) The dimensions of the engine are 70 mm. × 76 mm. = 293 c.c. (2.) Perhaps with a smaller jet you will be able to open the throttle fully. (3.) Probably the next size smaller. It is best to experiment.

Dismounting a Clutch.

? I have a 1914 3½ h.p. Premier fitted with a hub clutch. I wish to overhaul the clutch, and would be glad if you would tell me the way to take it to pieces. I have taken the wheel out of the machine and the cone and balls out, and have removed the belt rim, but cannot get the free-wheel off nor the end plates of the cone box (the hub cups). I have unscrewed the one on the free-wheel side about twelve threads, but it will not come out any more, although it will turn round. (1.) Does it need the pressure on the clutch springs releasing before unscrewing any more? A few hints on the dismantling and assembling of the clutch would be greatly appreciated. (2.) Does the Fit-All engine-shaft gear, made by Lake and Elliot, contain an adjustable pulley the same as an N.S.U.? (3.) Also what per cent. of decrease has the Fit-All from top to second gear? (4.) What is Messrs. Lake and Elliot's address? (5.) Is a Roc hub gear fitted with a free engine clutch?—J.G.

(1.) The left-hand hub disc is a left-hand thread. This should be taken off, and then the spring should be compressed and the locking ring removed, which should enable you to withdraw the section of the hub to which the free wheel is attached. In this case the Premier booklet should be of assistance to you. (2.) The Fit-All gear does not incorporate an adjustable pulley. (3.) Fifty per cent. reduction. (4.) Messrs. Lake and Elliot, Ltd., Albion Works, Braintree, Essex. (5.) Yes.

Running Costs.

? What do you consider is the cost per mile of running a motor bicycle just now, taking in tyre and other replacements, petrol, licences, etc.? The bicycle referred to is a 1914 Triumph, has been in use for four years, and the runs are mostly short.—J.D.

Your question does not allow of a definite answer, as everything depends upon the way in which the machine is treated and also upon the mileage run. We should say, however, that 1½d. per mile would leave a margin.

Two-stroke Timing and Lubrication.

? I have purchased a second-hand 1913 Scott, and have experienced the following troubles: (1.) The engine will not fire regularly, pops periodically in the exhaust pipe, and stops. I have timed the magneto thus: Spark fully advanced, piston ¼in. off top dead centre on the compression stroke. Is this correct? When running under load, the engine refuses to pull, if I retard the spark much. (2.) I cannot get any power out of the engine at all, unless I keep the carburetter needle raised so as to cause flooding. Why is this? (3.) I have experienced trouble with the driving chain to the back wheel. I took the machine to a garage, and was informed that it makes no difference with so long a drive whether the two sprockets are in absolute alignment or not; the only reason for the chain riding on the teeth was due to its having stretched. Is this the sole cause of its coming off?—R.B.W.

(1 and 2.) The trouble is caused either by a weak mixture or faulty timing of the magneto. The piston should be on dead centre and the points just fully broken when the spark lever is fully retarded. The popping in the exhaust pipe is probably caused by a weak mixture, accentuated somewhat by the late timing. You should first of all, therefore, time the magneto correctly and note the result. The reason that you cannot obtain any power from the engine unless the float needle is raised and jet flooded may be due to the fuel level in the float chamber being too low or the jet being too small. We presume you have made certain that there is no obstruction in the flow of fuel from tank to float chamber and float chamber to jet. (3.) The advice given to you at the garage is quite incorrect, as in all chain drives it is essential that the sprockets are perfectly aligned. The fact that the chain rides on the teeth is probably due to the sprockets affected being considerably worn. The cause of its coming off is partly due to the wheels being out of line, and partly to a stretched chain.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

READER'S REPLY.

Faulty Flywheel Key.

The query on page 576 of the issue of June 13th is rather an interesting one. There may not have been anything the matter with the material of the key, or surely it would have gone wrong between 1914 and 1918. I should feel more inclined to think "A.G." had upset the timing and put an extra strain on the key, which probably did not split in half, but sheared. It looks as if, in addition to tougher material, it wanted to be of stronger section. Some flywheels are fitted without a key at all, being merely jammed tightly on the taper.—V.A.H.

RECOMMENDED ROUTES.

LEICESTER TO SAFFRON WALDEN.—J.T.

Leicester, Market Harborough, Kettering, Thrapston, Huntingdon, Godmanchester, Cambridge, Chesterford, Saffron Walden. Distance approximately 85 miles.

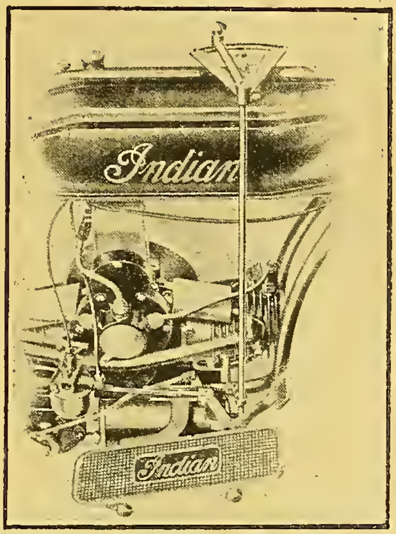
HALTWHISTLE TO BURTON-ON-TRENT.—E.D.

The best road is through Hexham to Newcastle, and then the Great North Road *viâ* Chester-le-Street, Neville's Cross, Ferryhill, Darlington, Scotch Corner, Boroughbridge, Aberford, Ferrybridge, to Doncaster; here to the right, and through Worksop, Mansfield, and Derby to Burton. If you do not mind rough roads and hills, a more interesting route will be: Haltwhistle, Knaresdale, Alston, Ashrigg, Middleton-in-Teesdale, Barnard Castle, Scotch Corner, and then on as above.

A FEATURE OF THE

1918 Indian LIGHT TWIN.

THE POWER PLANT
AND
GEAR CONTROL.



We regret that we are not in a position to supply motorcycles at the present time. But we can send 1918 descriptive list on application.

This applies to Great Britain only.

How many Miles per Cover?

A TYRE is worth the mileage it gives you—not what you pay for it. If you would know the value of a tyre (how it wears, if it is easily punctured or cut) you must ask a user of that Tyre—Many users of Beldam All British Tyres have recorded their experiences in a little Booklet entitled "Testimony," which will be sent post free on request. It will help to make clear to you why "once used always used" applies to Beldam Tyres, and that Quality, which means good service, always counts. It is because of the high quality of design, material, and workmanship that Beldam Tyres wear so long, and give such satisfaction.

Retreads

INVEST in a Beldam Retread: it costs shillings—it saves pounds. Read this testimony:

"I have done over 5,000 miles on the last retread you did for me about twelve months ago. I think it is money well spent in Beldam Retreads."
—A. G. W.

Send old covers of any make and we will quote you cost of retread.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☛ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

GODFREY'S

'I come from New Zealand, where SQUARE DEALS and Godfrey's mean the same thing."
(From an old Testimonial.)

"I am writing to you because I have heard you are RELIABLE in every way."
(Extract from a recent Letter.)

GODFREY'S have a WORLD-WIDE reputation for RELIABILITY, because the machines they sell are RELIABLE.

They are reliable, because each and every machine is dismantled and thoroughly overhauled before re-sale.

GODFREY'S have a large stock of New and Second-hand Solo and Sidecar Outfits equal to the most exacting work.
